> /solve/set/poor-mesh-numerics/print-poor-elements-count

- Number of marked cells based on default criteria       = 5
- Number of marked cells based on cell quality criteria  = 11
- Number of marked cells based on user-defined criteria  = 0
```

`/solve/set/poor-mesh-numerics/reset-poor-elements?`

Reset the poor cells included from user-defined registers and cell-quality metrics. The poor cells identified from the internal mesh check will be retained.

28.21.6. Warped-Face Gradient Correction

The warped-face gradient correction (WFGC) is designed to improve gradient accuracy for all gradient methods—cell based, node based and least squares based gradients. WFGC is recommended for 3D simulations on polyhedral, hexahedral, and hybrid meshes (meshes containing a mix of hexahedral and polyhedral cells), and it is enabled by default for any mesh that contains polyhedra. Note that these types of mesh cells may not have perfectly planar faces, which can affect the overall accuracy of the Green Gauss surface integral.

WFGC computations aim to resolve gradient accuracy degradation due to very high aspect ratio, cells with non-flat faces in the boundary layer, and highly deformed cells where the formal cell centroid lies outside of the control volume.

WFGC has two modes, fast mode and memory saving mode. Fast mode does not increase gradient computation time for static meshes (except for cases that use the **Green-Gauss Node Based** gradient method with a turbulence model), but it does require additional memory. There is roughly a 22% increase in memory for a basic flow solution, but this additional overhead does not change as more models

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(turbulence, species transport, radiation, and so on) are enabled. Memory saving mode does not increase memory consumption, but it slows down iteration execution time for static and dynamic meshes.

Important

Enabling **Warped-Face Gradient Correction** through the **Solution Methods** task page enables fast mode. To switch to memory saving mode, you must use the TUI command `solve/set/warped-face-gradient-correction/enable?` and enter `no` in response to the `use fast mode?` prompt.

WFGC does *not* correct for cells with left-handed faces. If your mesh contains left-handed faces, you must use poor mesh numerics to obtain a stable solution.

28.22. Solution Steering

For additional information, see the following sections:

28.22.1. Overview of Solution Steering
28.22.2. Solution Steering Strategy
28.22.3. Using Solution Steering

28.22.1. Overview of Solution Steering

Solution steering in the density-based implicit solver provides you with an expert system that will help navigate the flow solution from a starting initial guess to a converged solution with minimum user interaction. When you apply solution steering, you will be required to select the type of flow that best characterizes the solution domain and the maximum desired accuracy, and then allow the solver to take the solution to convergence. As the solver proceeds with the solution iteration, certain solver parameters will be adjusted behind the scenes to insure that a converged solution to steady-state is possible.

Important

Solution steering is available only for steady-state flows in the density-based implicit solver.

28.22.2. Solution Steering Strategy

The convergence to steady-state solution is achieved in two stages. The parameters that are used in these stages are determined and set based on user input for the type of flow that can best characterize the solution domain. The type of flows available for selection are classified based on flow compressibility as well as the dominant flow Mach number in the solution domain.

The following flow types are available:

- Incompressible (if the flow is incompressible, that is density is constant)
- Subsonic (if the flow is compressible and M<0.75)
- Transonic (if the flow is compressible and 0.65<M<1.2)
- Supersonic (if the flow is compressible and 1.10< M<2.5)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Hypersonic (if the flow is compressible and 2.0< M)

Important

There is no exact Mach number cut-off for these regions, therefore, the above Mach number ranges are just a simple guideline to help you select a flow type.

Solution steering will typically perform full multigrid (FMG) initialization followed by two iterative stages. The purpose of each stage is described below.

28.22.2.1. Initialization

Immediately before the start of the iteration, solution steering will perform full multigrid initialization to obtain the best possible initial starting solution.

Stage 1:

The purpose of Stage 1 is to navigate the solution from the difficult initial phase of the solution toward convergence by insuring maximum stability. During this stage, the solution is advanced gradually from 1st-order accuracy to maximum accuracy (user specified and typically 2nd-order) at a constant low CFL value.

Stage 2:

In this stage the solution is driven hard towards convergence by regular adjustments of the CFL value to insure fast convergence as well as to prevent possible divergence.

In stage 2, the residual history is monitored and analyzed through regular intervals to determine if an increase or decrease in CFL value is needed to obtain fast convergence or to prevent divergence.

28.22.3. Using Solution Steering

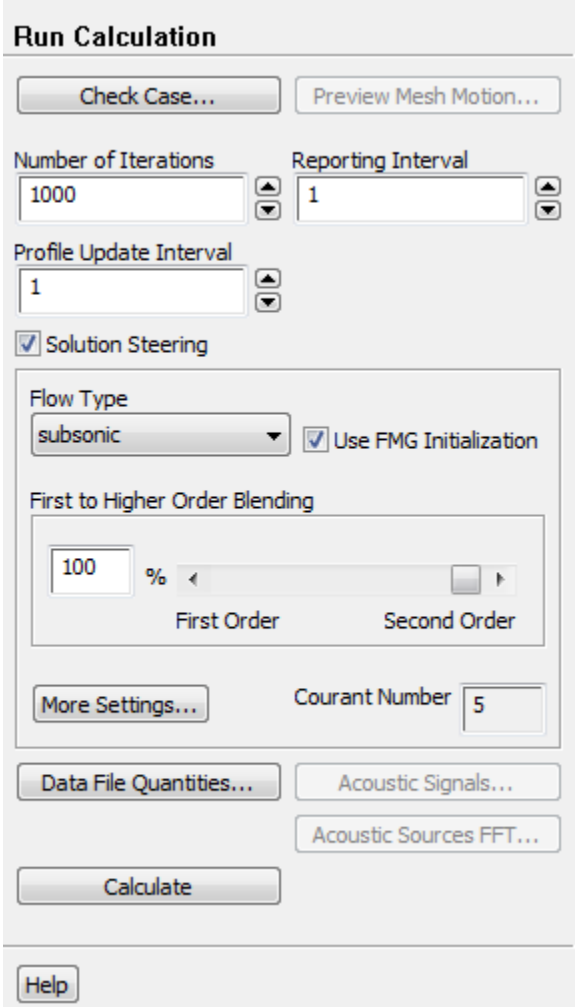
Solution steering is disabled by default. However, when the following criteria are met, the solution steering feature will become available for selection:

Feature	Setting
Solver Type	Density Based
Solver Formulation	Implicit
Time Formulation	Steady
Data is valid (either data file has been read or flow has been initialized)	

To turn on solution steering, enable the **Solution Steering** option as shown in Figure 28.53: The Run Calculation Task Page with Solution Steering Enabled (p. 1677).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.53: The Run Calculation Task Page with Solution Steering Enabled



The **Run Calculation** task page will then expand to display the solution steering main controls (see Figure 28.53: The Run Calculation Task Page with Solution Steering Enabled (p. 1677)). To obtain a flow solution using solution steering, you will need to perform the following:

1. Select the type of flow.
2. Select the maximum accuracy desired (first to second order blending).
3. Click **Calculate**.

You can also adjust the number of iterations, or customize the parameters of the solution steering if the default setting is not sufficient for the type of flow problem being solved.

Before using solution steering, you will need to prepare and set up the case as usual as described in the Getting Started Manual.

After **Solution Steering** is enabled, specify the following:

Flow Type

allows you to select the flow type that best describes the flow in the solution domain. Five choices are available: **incompressible**, **subsonic**, **transonic**, **supersonic**, and **hypersonic**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

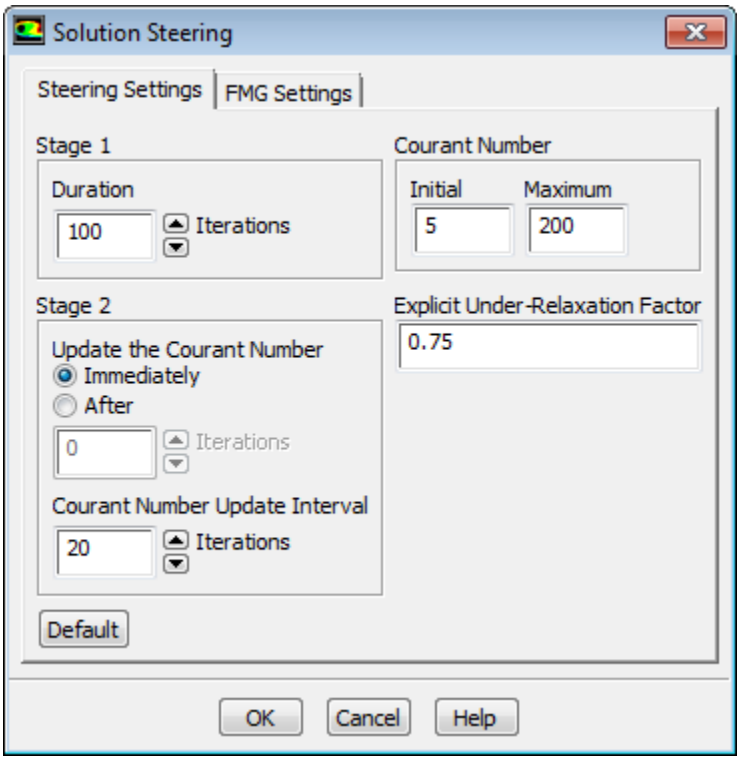
FMG Initialization
when enabled allows for full multigrid initialization before starting stages 1 and 2. FMG initialization is enabled by default.

First to Higher Order Blending
allows you to reduce the desired solution accuracy by selecting a blending factor less than 100%. The default setting is 100%. See First-to-Higher Order Blending in the Theory Guide for more information. The blending factor will be grayed out if **Second Order Upwind** discretization for the **Flow** equations is not selected in the **Solution Methods** task page. The solution accuracy may be reduced (typical values are 75% or 50%) if it is not possible to obtain a converged solution with the maximum second-order accuracy (that is blending = 100%)

Courant Number
in the **Run Calculation** task page is a non-adjustable field displaying the current CFL number, which allows you to view it during the calculation.

More Settings...
opens the **Solution Steering** dialog box, providing a host of settings that control the solution steering strategy, as shown in Figure 28.54: The Solution Steering Dialog Box (p. 1678).

Figure 28.54: The Solution Steering Dialog Box



The **Solution Steering** dialog box, shown in Figure 28.54: The Solution Steering Dialog Box (p. 1678), contains two tabs. The **Steering Settings** tab sets the solution steering parameters and the **FMG Settings** sets the full multigrid initialization parameters.

In the **Steering Setting** tab, you can modify the parameters used in Stages 1 and 2.

Stage 1
Duration is the number of iterations in stage 1. The CFL number used during these iterations is set in the **Initial** field, in the **Courant Number** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Stage 2

The Courant number update in stage 2 can start immediately after the end of stage 1, or after a certain designated number of iterations. If the Courant number update is to start immediately after stage 1 then **Immediately** should be selected (this is the default option). If the Courant number update is desired after some lagged period of iterations, then **After** should be selected and the lag in the number of iterations should be entered in the field below it. The frequency at which the Courant number is updated is defined in **Courant Number Update Interval** field.

Courant Number

Initial is the starting Courant number and **Maximum** is the maximum allowed Courant number. The solution steering algorithm will not allow the solver to exceed the maximum Courant number, but will allow the solver to use a Courant number less than the initial Courant number if divergence in the solution has occurred.

Explicit Under-Relaxation Factor

allows the solution to be under-relaxed to improve convergence. The under-relaxation value is determined by the **Flow Type** that you selected in the **Run Calculation** task page, when **Solution Steering** was enabled. In general, you do not need to alter the default value set in this field. Refer to Under-Relaxation of Variables in the Theory Guide for more information about explicit relaxation.

Default

is available in the **Steering Settings** tab to reset any changes made to the parameters to their original default values.

In the **FMG Settings** tab (Figure 28.55: The FMG Settings Tab in the Solution Steering Dialog Box (p. 1680)), the **Number of multigrid levels** and **Number of Cycles** in each **Level**, as well as the **FMG Courant Number** used in the FMG initialization can be adjusted. The default values used in the multigrid settings are determined from the type of flow that you selected, the size of the mesh, and the flow dimensionality. The **Default** button is used to reset any changes to the original default values. For more information about FMG initialization, refer to Full Multigrid (FMG) Initialization (p. 1595).

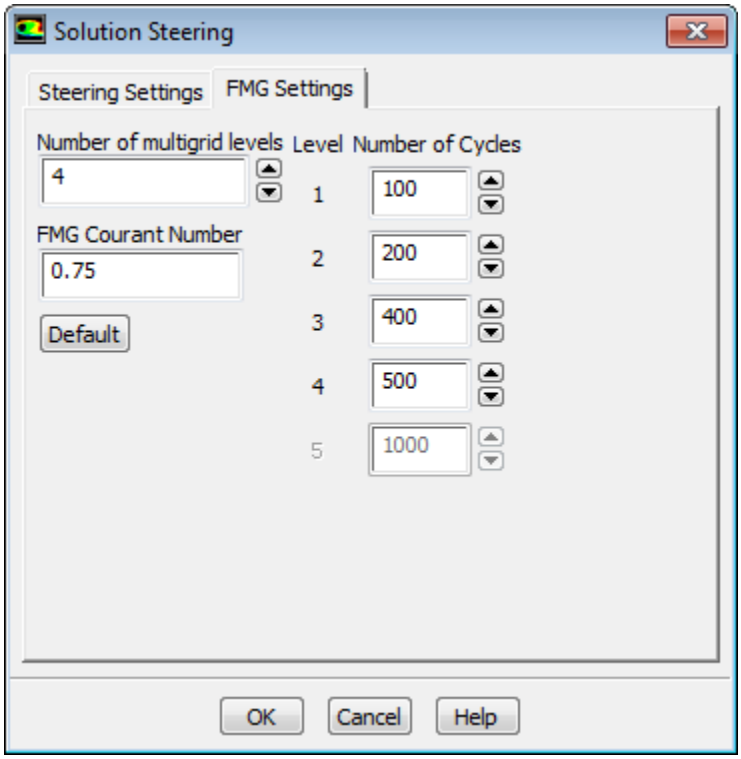
Figure 28.55: The FMG Settings Tab in the Solution Steering Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 29: Adapting the Mesh

The solution-adaptive mesh refinement feature of ANSYS Fluent allows you to refine and/or coarsen your mesh based on geometric and numerical solution data. In addition, ANSYS Fluent provides tools for creating and viewing adaption fields customized to particular applications. For information about the theory behind mesh adaption in ANSYS Fluent, see Adapting the Mesh in the Theory Guide. Information about using the adaption process in ANSYS Fluent is described in detail in the following sections.

29.1. Using Adaption
29.2. Boundary Adaption
29.3. Gradient Adaption
29.4. Dynamic Gradient Adaption
29.5. Isovalue Adaption
29.6. Region Adaption
29.7. Volume Adaption
29.8. Yplus/Ystar Adaption
29.9. Anisotropic Adaption
29.10. Geometry-Based Adaption
29.11. Registers
29.12. Mesh Adaption Controls

29.1. Using Adaption

Two significant advantages of the unstructured mesh capability in ANSYS Fluent are:

- reduced setup time compared to structured meshes
- the ability to incorporate solution-adaptive refinement of the mesh

By using solution-adaptive refinement, you can add cells where they are needed in the mesh, thus enabling the features of the flow field to be better resolved. When adaption is used properly, the resulting mesh is optimal for the flow solution because the solution is used to determine where more cells need to be added. Thus, computational resources are not wasted by the inclusion of unnecessary cells, as occurs in the structured mesh approach. Also, the effect of mesh refinement on the solution can be studied without completely regenerating the mesh.

Note

When you perform mesh adaption in a parallel computation, a load balancing step will be performed by ANSYS Fluent by default.

The automatic load balancing will not occur in conjunction with dynamic adaption. See Dynamic Gradient Adaption (p. 1690) for information on dynamic adaption, and Load Balancing (p. 2044) for information on load balancing in parallel ANSYS Fluent. For information about the static adaption process, see Static Adaption Process in the Theory Guide.

For additional information, see the following sections:

29.1.1. Adaption Example

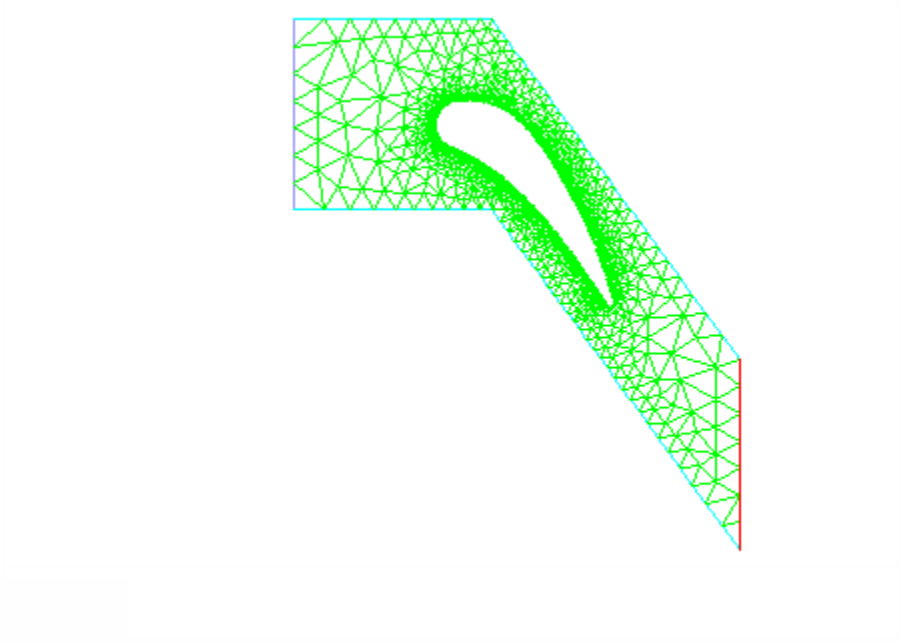
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.1.2. Adaption Guidelines

29.1.1. Adaption Example

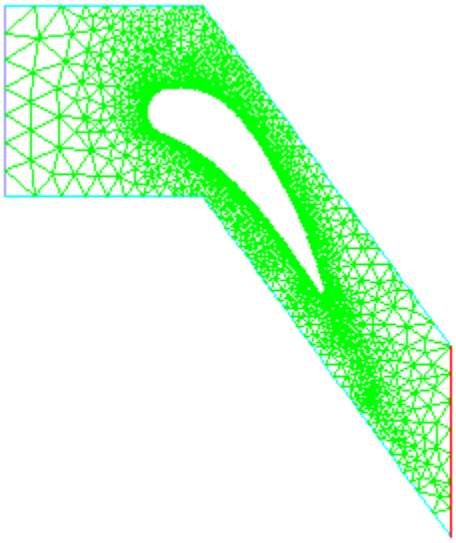
An example of the effective use of adaption is in the solution of the compressible, turbulent flow through a 2D turbine cascade. The initial mesh around the blade is fine, as shown in Figure 29.1: Turbine Cascade Mesh Before Adaption (p. 1682). The surface node distribution thus provides adequate definition of the blade geometry, and enables the turbulent boundary layer to be properly resolved without further adaption. On the other hand, the mesh on the inlet, outlet, and periodic boundaries is comparatively coarse. To ensure that the flow in the blade passage is appropriately resolved, solution-adaptive refinement was used to create the mesh shown in Figure 29.2: Turbine Cascade Mesh after Adaption (p. 1683).

Figure 29.1: Turbine Cascade Mesh Before Adaption



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 29.2: Turbine Cascade Mesh after Adaption



While the procedure for solution adaption will vary according to the flow being solved, it is instructive to examine the adaption process used for the turbine cascade shown in the previous figure. Though this example involves compressible flow, the general procedure is applicable for incompressible flows as well.

1. Display contours of pressure adaption function to determine a suitable refinement threshold (see Gradient Adaption (p. 1688)).

2. "Mark the cells within the refinement threshold, creating a refinement register (see Adaption Registers in the Theory Guide and Gradient Adaption (p. 1688)).

3. Repeat the process described in steps 1 and 2, using gradients of Mach number as a refinement criterion.

4. To refine in the wake region, use isovalues of total pressure as a criterion (see Isovalue Adaption (p. 1691)). This causes cells within the boundary layer and the wake to be marked, since these are both regions of high total-pressure loss.

5. Use the Manage Adaption Registers Dialog Box (p. 2728) to combine the three refinement registers into a single register (see Manipulating Adaption Registers (p. 1701)).

6. Limit the minimum cell volume for adaption to prevent the addition of cells within the boundary layer, where the mesh was judged to be fine enough already (see Mesh Adaption Controls Dialog Box (p. 2730)).

7. Refine the cells contained in the resulting adaption register (see Manipulating Adaption Registers (p. 1701)).

8. Perform smoothing using the Improve Mesh Dialog Box (p. 2715); see Improving the Mesh by Smoothing and Swapping (p. 230) for details.

The effect of refining on gradients is evident in the finer mesh ahead of the leading edge of the blade and within the blade passage (Figure 29.2: Turbine Cascade Mesh after Adaption (p. 1683)). The finer mesh in the wake region is due to the adaption using isovalues of total pressure.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.1.2. Adaption Guidelines

The advantages of solution-adaptive refinement, when used properly (as in the turbine cascade example in Adaption Example (p. 1682)), are significant. However, this capability must be used carefully to avoid certain pitfalls. Some guidelines for proper usage of solution-adaptive refinement are as follows:

- The surface mesh must be fine enough to adequately represent the important features of the geometry.

  For example, it would be bad practice to place too few nodes on the surface of a highly-curved airfoil, and then use solution refinement to add nodes on the surface. The surface will always contain the facets contained in the initial mesh, regardless of the additional nodes introduced by refinement.

- The initial mesh should contain sufficient cells to capture the essential features of the flow field.

  Consider the following example, in which you want to predict the shock forming around a bluff body in supersonic flow. To obtain a reasonable first solution, the initial mesh should contain enough cells and also have sufficient resolution to represent the shape of the body. Subsequent gradient adaption can be used to sharpen the shock and to establish a mesh-independent solution.

- Polyhedral cells are not eligible for adaption. The presence of polyhedral cells in a mesh may or may not limit the eligibility of other cells for adaption, depending on the manner in which the polyhedral cells were created:

  – If the domain was converted to polyhedra (see Converting the Domain to a Polyhedra (p. 199)), then no part of the mesh can be adapted (even if hexahedral cells are present in the mesh after conversion).

  – If the polyhedra are a result of converting skewed tetrahedral cells (see Converting Skewed Cells to Polyhedra (p. 204)) or converting the transitional cells of a hexcore mesh, then the nonpolyhedral cells may be adapted. The polyhedral cells, however, will be automatically unmarked from the register when adaption is initiated and will remain unchanged.

- Obtain a reasonably well-converged solution before performing an adaption. If you adapt to an incorrect solution, cells will be added in the wrong region of the flow.

  Use careful judgment in deciding how well to converge the solution before adapting, because there is a trade-off between adapting too early to an unconverged solution and wasting time by continuing to iterate when the solution is not changing significantly. This does not directly apply to dynamic adaption, because here the solution is adapted either at every iteration or at every time step, depending on which solver is being used.

- Write a case and data file before starting the adaption process. If you generate an undesirable mesh, you can restart the process with the saved files. This does not directly apply to dynamic adaption, because here the solution is adapted either at every iteration or at every time step, depending on which solver is being used.

- Select suitable variables when performing gradient adaption. For some flows, the choice is clear. For instance, adapting on gradients of pressure is a good criterion for refining in the region of shock waves. In most incompressible flows, however, it makes little sense to refine on pressure gradients. A more suitable parameter in an incompressible flow might be mean velocity gradients. If the flow feature of interest is a turbulent shear flow, it will be important to resolve the gradients of turbulent kinetic energy and turbulent energy dissipation, so these might be appropriate refinement variables. In reacting flows, temperature or concentration (or mole or mass fraction) of reacting species might be appropriate.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Do not over-refine a particular region of the solution domain. It causes very large gradients in cell volume. Such poor adaption practice can adversely affect the accuracy of the solution.

29.2. Boundary Adaption

This section describes how to perform boundary adaption. For more information, see Boundary Adaption in the Theory Guide.

For additional information, see the following section:
29.2.1. Performing Boundary Adaption

29.2.1. Performing Boundary Adaption

You can perform the boundary adaption in three different ways based on:

- number of cells

  In this case, the distance of a cell from the boundary is measured in number of cells.

- normal distance

  In this case, the cell refinement is based on the normal distance of a cell from the boundary.

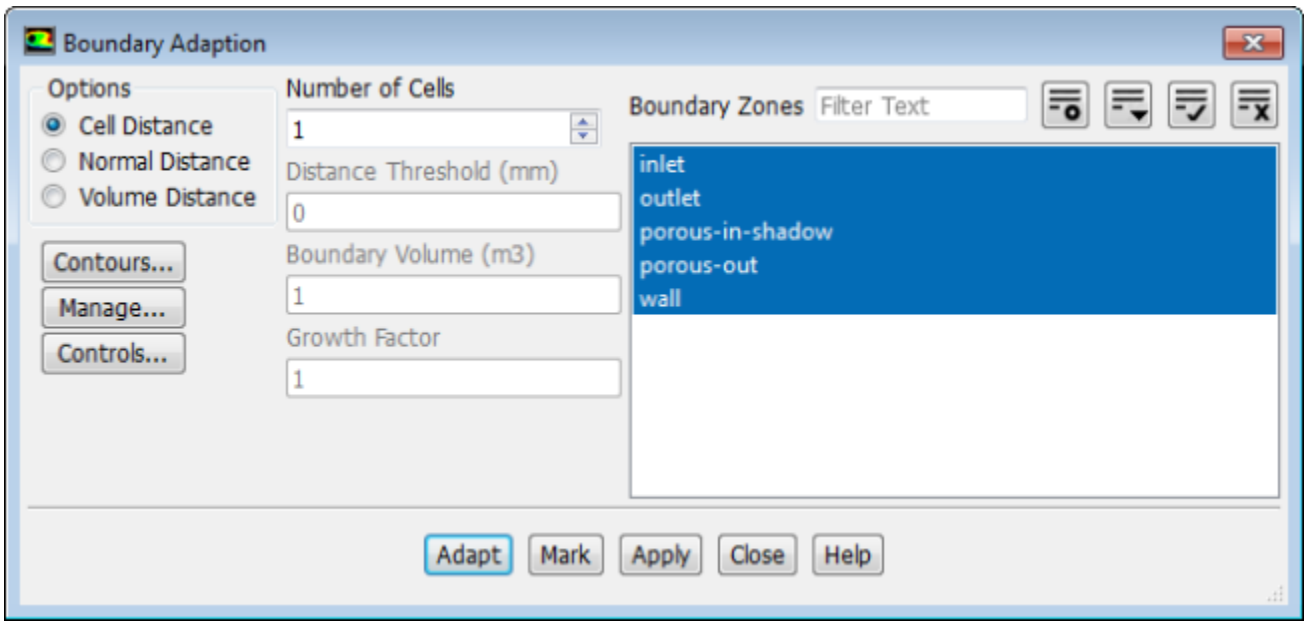
- target boundary volume

  In this case, the cell refinement is based on a target boundary volume and growth factor.

You can use any of these methods in the Boundary Adaption Dialog Box (p. 2673) (Figure 29.3: The Boundary Adaption Dialog Box (p. 1685)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Boundary...

Figure 29.3: The Boundary Adaption Dialog Box



29.2.1.1. Boundary Adaption Based on Number of Cells

The procedure for performing adaption based on the distance of a cell from the boundary in terms of the number of cells is as follows:

1. In the Boundary Adaption Dialog Box (p. 2673) (Figure 29.3: The Boundary Adaption Dialog Box (p. 1685)), select **Cell Distance** under **Options**, choose the boundary zones near which you want to refine cells in the **Boundary Zones** list, and click **Apply**.

   This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Click the **Contours...** button to open the Contours Dialog Box (p. 2676).

   a. Enable **Filled** contours, disable **Node Values**.

   b. Select **Adaption...** and **Boundary Cell Distance** in the **Contours of** drop-down list.

   c. Select the appropriate surfaces (3D only).

   d. Click **Display** to see the location of cells with each value of boundary cell distance.

      By displaying different ranges of values (as described in Specifying the Range of Magnitudes Displayed (p. 1759)), you can determine the cell distance of the cells you want to adapt.

3. Set the **Number of Cells** to the desired value.

   - If you retain the default value of 1, only those cells that have edges (2D) or faces (3D) on the specified boundary zone(s) (that is, those cells with a boundary cell distance of 1) will be marked or adapted.
   - If you increase the value to 2, cells with a boundary cell distance of 2 will also be marked/adapted, and so on.

4. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).

5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.2.1.2. Boundary Adaption Based on Normal Distance

The procedure for performing refinement based on a cell's normal distance from the boundary (that is, the distance between the centroid of a cell and the boundary) is as follows:

1. In the Boundary Adaption Dialog Box (p. 2673), select **Normal Distance** under **Options**, choose the boundary zones near which you want to refine cells in the **Boundary Zones** list, and click **Apply**.

   This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Open the Contours Dialog Box (p. 2676) by clicking on the **Contours...** button.

   a. Enable **Filled** contours, disable **Node Values**.

   b. Choose **Adaption...** and **Boundary Normal Distance** in the **Contours of** drop-down list.

   c. Select the appropriate surfaces (3D only).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. Click **Display** to see the location of cells with each value of normal distance.

   By displaying different ranges of values (as described in Specifying the Range of Magnitudes Displayed (p. 1759)), you can determine the normal distance of the cells you want to adapt.

3. Set the **Distance Threshold** to the desired value. Cells with a normal distance to the selected boundary zone(s) less than or equal to this value will be marked or adapted.

4. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).

5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.2.1.3. Boundary Adaption Based on Target Boundary Volume

This boundary adaption allows you to produce exponentially larger (or smaller) cells as you get further from the boundaries. The cells are marked for refinement based on the following equation:

$$V_n > V_{boundary} e^{\alpha d} \tag{29.1}$$

where V_n is the cell volume, $V_{boundary}$ is the specified boundary volume (**Boundary Volume**), α is the exponential growth factor (**Growth Factor**), and d is the normal distance of the cell centroid from the selected boundaries. $V_{boundary} e^{\alpha d}$ is the target volume for a cell.

The procedure for this type of boundary refinement is as follows:

1. In the Boundary Adaption Dialog Box (p. 2673), select **Volume Distance** under **Options**, set the **Boundary Volume** and **Growth Factor** to the desired values, select the boundary zones in the **Boundary Zones** list where you want the **Boundary Volume** to be applied, and click **Apply**.

   This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Open the Contours Dialog Box (p. 2676) by clicking the **Contours...** button.

   a. Enable **Filled** contours, disable **Node Values**.

   b. Choose **Adaption...** and **Boundary Volume Distance** in the **Contours of** drop-down list.

   c. Select the appropriate surfaces (3D only).

   d. Click **Display** to see the contours of the target volume.

      By displaying different ranges of values (as described in Specifying the Range of Magnitudes Displayed (p. 1759)), you can determine the normal distance of the cells you want to adapt.

   You can modify the values of the inputs (**Boundary Volume**, **Growth Factor**, and/or **Boundary Zones**), click **Apply** in the **Boundary Adaption** dialog box, and then redisplay the contour plot to visualize the modified target volume distribution.

3. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.3. Gradient Adaption

This section describes how to perform gradient adaption. For more information, see Gradient Adaption in the Theory Guide.

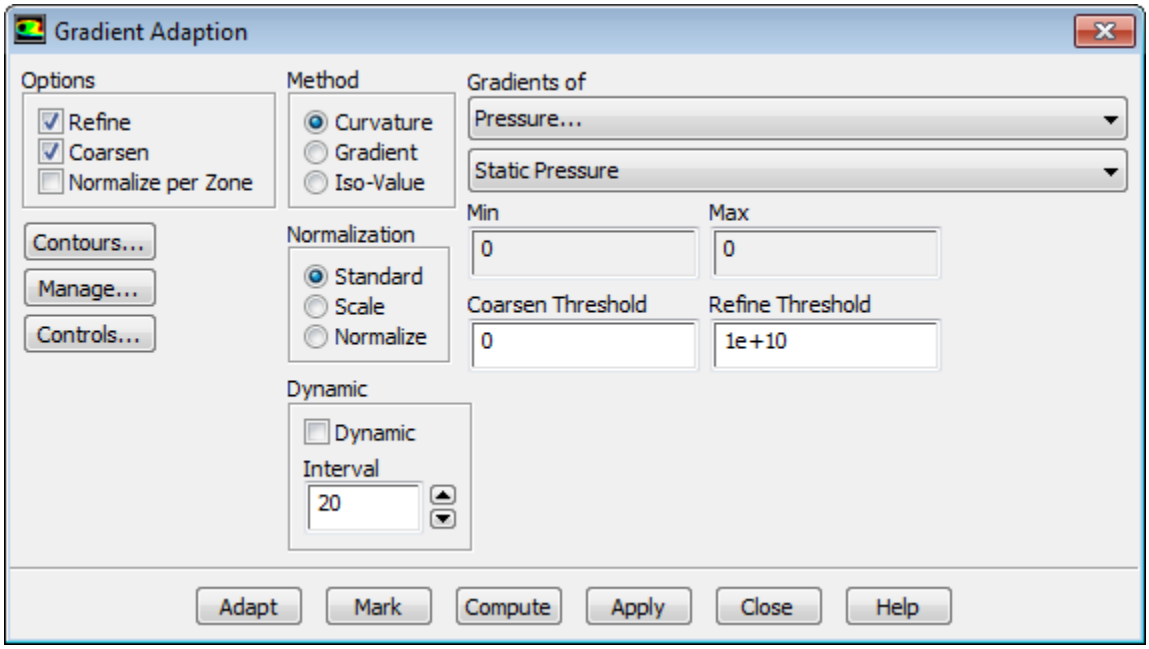
For additional information, see the following section:
29.3.1. Performing Gradient Adaption

29.3.1. Performing Gradient Adaption

The Gradient Adaption Dialog Box (p. 2710) (Figure 29.4: The Gradient Adaption Dialog Box (p. 1688)) allows you to perform gradient adaption.

Setting Up Domain → Adapt → Mark/Adapt Cells → Gradient...

Figure 29.4: The Gradient Adaption Dialog Box



The procedure for performing gradient adaption is as follows:

1. Select the appropriate adaption method.

   - **Curvature** is the default method, and is recommended for problems with smooth solutions.
   - **Gradient** is recommended for problems with strong shocks (for example, supersonic inviscid flows).
   - **Iso-Value** is recommended for problems where derivatives are not helpful, or when you want to customize the adaption criterion (using custom field functions, user-defined scalars, and so on).

2. Select a **Normalization** method:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Standard**, if normalization of the gradient or curvature is not to be performed.
- **Scale**, if the gradient or curvature is to be scaled by the average value in the domain.
- **Normalize**, if the gradient or curvature is to be scaled by the maximum value of the variable in the domain (that is, the gradient or curvature is bounded by [0, 1]).

Using either scaling or normalization makes the setting of the refine and coarsen thresholds much simpler, and almost independent of the current solution and specific problem.

This is especially important when using the automated dynamic adaption process.

3. Select the required solution variable in the **Gradients of** drop-down list.
4. Click **Compute**.
5. Click **Contours...** to open the Contours Dialog Box (p. 2676).

   a. Enable **Filled** contours, disable **Node Values**, and select **Adaption...** and **Existing Value** in the **Contours of** drop-down lists.

   b. Select the appropriate surfaces (3D only).

   c. Click **Display** to see the location of cells with each curvature value.

      By displaying different ranges of values (as described in Specifying the Range of Magnitudes Displayed (p. 1759)), you can determine the range of curvatures for which you want to adapt cells.

      If you are using normalization, the range for the curvatures of any variable will always be [0, 1].

6. Set the values for **Refine Threshold**.

   Cells with gradient values above this value will be either marked or refined.

7. Select the **Normalize per Zone** option for cases where different flow conditions exist for different zones.

   This approach of *zonal normalization* normalizes (that is, scales) each zone of the domain, in contrast to normalization on the whole domain. This approach is useful for dynamic adaption (see Dynamic Gradient Adaption (p. 1690) for details), where you want to solve the flow problem involving different flow intensities in the different cell zones.

   If you use gradient adaption for the whole domain, the small gradients may be neglected in comparison to large gradients depending on the adaption threshold. Enabling **Normalize per Zone** in the Gradient Adaption Dialog Box (p. 2710) will scale or normalize each zone independently, which means the strongest gradient for each zone is considered separately for adaption of that zone.

   Note

   If you expect gradients of different intensities throughout the domain and you want to resolve them, separate the domain into different zones for precise zonal normalization. This approach is referred as zonal adaption.

8. If you want to coarsen the mesh, set the **Coarsen Threshold** to a nonzero value. Cells with gradient values below the specified value will be either marked or coarsened.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. To set adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click **Controls...** to open the Mesh Adaption Controls Dialog Box (p. 2730).

10. To mark the cells for adaption (refinement/coarsening), click **Mark**. You can then place the cells in an adaption register, which can be manipulated (as described in Manipulating Adaption Registers (p. 1701)). To perform the adaption immediately, click **Adapt**.

Note

To disable refinement, coarsening, or marking for refinement/coarsening, disable the **Refine** or **Coarsen** option before marking or adapting.

29.4. Dynamic Gradient Adaption

This section describes how to perform dynamic gradient adaption. In contrast with the static gradient adaption (Gradient Adaption in the Theory Guide), dynamic gradient adaption is a fully automated process. For time dependent and for steady-state problems, you can perform the entire solution without changing the initial settings. That is, you can let the solver periodically perform adaptions without changing/entering any parameter.

Note

Dynamic gradient adaption based on custom field functions is not supported when running ANSYS Fluent in parallel.

For additional information, see the following section:
29.4.1. Dynamic Gradient Adaption Approach

29.4.1. Dynamic Gradient Adaption Approach

The dynamic gradient adaption executes the gradient adaption automatically. Though all options of gradient adaption are valid for the dynamic gradient adaption, some specific settings are recommended:

In the **Gradient Adaption** dialog box:

- Enable the **Refine** and **Coarsen** options.
- The **Normalize per Zone** enables zonal normalization for the dynamic adaption. See Performing Gradient Adaption (p. 1688) (step 7) for details.
- For **Normalization**, use either the **Scale** or the **Normalize** option.

  *The non-normalized values of the gradient or the curvature of a variable (obtained by selecting **Standard** for the **Normalization**) are generally strongly solution dependent, and therefore would require re-adjustment of the **Coarsen Threshold** and **Refine Threshold** as the solution proceeds.*

- For dynamic adaption, scaling is preferred if you want to resolve regions of small values of the gradient (or curvature/isovalues) accurately, in addition to the region of highest gradient (or curvature/isovalues).

  Scaling does not take very high values of the gradient or curvature into account to the degree that normalization does.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The starting values for **Refine Threshold** and **Coarsen Threshold** are 1e10 and 0 respectively.

  The more refinement you want, the smaller these values should be.

- Specify the **Interval** between two consecutive automatic mesh adaptions. Depending on whether you are performing a steady-state or a time-dependent solution, specify **Interval** in iterations or time steps, respectively.

  This value depends on the type of problem solved and the time step used (where applicable). For steady-state problems, values of 100 or higher are reasonable. For time-dependent problems, values of 10 or lower are often required.

  If you are using the density-based explicit solver with explicit transient formulation, your input will be in number of iterations.

In the **Mesh Adaption Controls** dialog box:

- Set values for **Min # of Cells**, **Max # of Cells**, **Max Level of Refine**, or **Min Cell Volume**.

  The limits for the **Min # of Cells** and **Max # of Cells** can affect the **Coarsen Threshold** and **Refine Threshold** values. If either the **Min # of Cells** or the **Max # of Cells** are violated, the **Coarsen Threshold** or the **Refine Threshold** are adjusted to fulfill the limits for the **Min # of Cells** or the **Max # of Cells**.

- The default value for **Max Level of Refine** is 2, which is a good start for most problems. If required, you can increase this value.

  Important

  Even in a 2D problem, the default value of 2 can increase the number of cells by a factor of 16 in the adapted regions. A value of zero leaves this parameter unbounded: in this case, you should use a suitable limit for **Min Cell Volume**.

29.4.1.1. Examples of Dynamic Gradient Adaption

Example 1: Steady-state problem

Consider a supersonic flow over a blunt body. To determine the wave drag for such problem, first resolve the shock wave. Start with a coarse mesh and set up dynamic adaption. As you start iterating the solution, the solver will produce a blurred shock, probably in an incorrect location. After the adaptions, the shock will become sharper and move into the correct location.

Example 2: Time-dependent problem

Consider a traveling shock wave. To determine the precise pressure amplitudes and arrival times at a number of locations, you must resolve the shock wave over the time, so that you can maintain the correct shock strength and its location. Dynamic adaption is efficient in this case, as it refines the mesh near the shock, and at the same time, it coarsens the mesh wherever needed.

29.5. Isovalue Adaption

This section describes how to perform isovalue adaption. For more information, see Isovalue Adaption in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

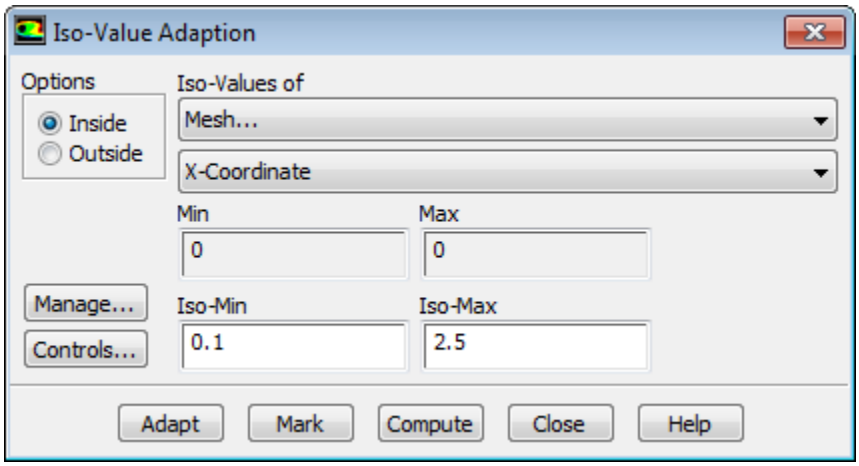
For additional information, see the following section:
29.5.1. Performing Isovalue Adaption

29.5.1. Performing Isovalue Adaption

You can perform isovalue adaption in the Iso-Value Adaption Dialog Box (p. 2722) (Figure 29.5: The Iso-Value Adaption Dialog Box (p. 1692)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Iso-Value...

Figure 29.5: The Iso-Value Adaption Dialog Box



The general procedure for performing isovalue adaption is as follows:

1. Select the desired solution variable in the **Iso-Values of** drop-down lists and click **Compute** to update the **Min** and **Max** fields.
2. Choose the **Inside** or **Outside** option and set the **Iso-Min** and **Iso-Max** values.
   - If you choose **Inside**, cells with isovalues between **Iso-Min** and **Iso-Max** will be marked or refined.
   - If you choose **Outside**, cells with isovalues less than **Iso-Min** or greater than **Iso-Max** will be marked or refined.
3. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).
4. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.6. Region Adaption

This section describes how to perform region adaption. For more information, see Region Adaption in the Theory Guide.

For additional information, see the following section:
29.6.1. Performing Region Adaption

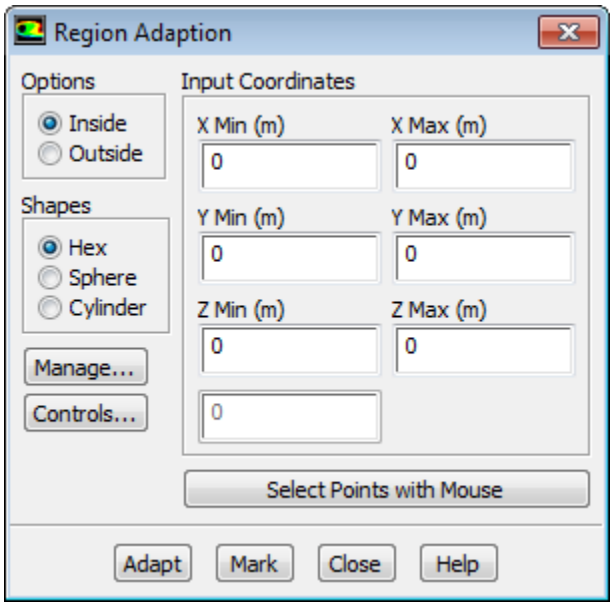
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.6.1. Performing Region Adaption

You will perform region adaption in the Region Adaption Dialog Box (p. 2782) (Figure 29.6: The Region Adaption Dialog Box (p. 1693)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Region...

Figure 29.6: The Region Adaption Dialog Box



The procedure for performing region adaption is as follows:

1. In the Region Adaption Dialog Box (p. 2782), select the **Inside** or **Outside** option.

   - If you choose **Inside**, cells with centroids within the specified region will be marked or refined.
   - If you choose **Outside**, cells with centroids outside the specified region will be marked or refined.

2. Specify the shape of the region.

   In 2D, you may specify a **Quad** (that is, a quadrilateral), **Circle**, or **Cylinder** by making a selection from the **Shape** group box. In 3D, your options include **Hex** (that is, a hexahedron), **Sphere**, or **Cylinder**.

3. Define the region by entering values into the dialog box or by using the mouse.

   In the dialog box, the inputs are as follows:

   - To define a hexahedron or quadrilateral, enter the coordinates of two points defining the diagonal of the box.

     For a hexahedron, define **X Min**, **Y Min**, and **Z Min**, as well as **X Max**, **Y Max**, and **Z Max**. For a quadrilateral, define **X Min** and **Y Min**, as well as **X Max** and **Y Max**.

   - To define a sphere or circle, enter the values for the **Radius** and the coordinates of its center: **X Center**, **Y Center**, and **Z Center** for a sphere, or **X Center** and **Y Center** for a circle.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To define a cylinder, enter the value for the **Radius** and the minimum and maximum coordinates defining the cylinder axis: **X-Axis Min**, **Y-Axis Min**, and **Z-Axis Min**, as well as **X-Axis Max**, **Y-Axis Max**, and **Z-Axis Max** for 3D, or **X-Axis Min** and **Y-Axis Min**, as well as **X-Axis Max** and **Y-Axis Max** for 2D. In 2D, this will be the width of the resulting rectangle.

4. To define the region using the mouse, click the **Select Points with Mouse** button. Using the right mouse button, select the input coordinates from a display of the mesh or solution field. After selecting the points, the values will be loaded automatically into the appropriate fields in the dialog box. See Controlling the Mouse Button Functions (p. 1800) for details about mouse button functions.

   You have the option of editing these values before marking or adapting.

   - To define a hexahedron or quadrilateral, select the two points of the diagonal in any order.
   - To define a sphere or circle, first select the location of the centroid and then select a point that lies on the sphere/circle (that is, a point that is one radius away from the centroid).
   - To define a cylinder, first select the two points that define the cylinder axis and then select a point that is one radius away from the axis.

5. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).

6. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.7. Volume Adaption

This section describes how to perform volume adaption. For more information, see Volume Adaption in the Theory Guide.

For additional information, see the following section:
29.7.1. Performing Volume Adaption

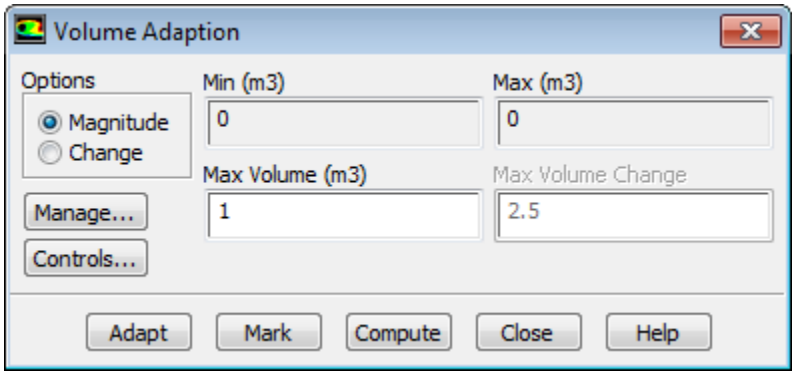
29.7.1. Performing Volume Adaption

You will perform volume adaption in the Volume Adaption Dialog Box (p. 2838) (Figure 29.7: The Volume Adaption Dialog Box (p. 1695)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Volume...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 29.7: The Volume Adaption Dialog Box



The procedure for performing volume adaption is as follows:

1. In the Volume Adaption Dialog Box (p. 2838), specify whether you want to adapt based on volume magnitude or volume change by selecting the **Magnitude** or **Change** option.

2. Click **Compute** to update the **Min** and **Max** fields. These fields will show the range of cell volumes or cell volume changes (defined in Volume Adaption Approach in the Theory Guide), depending on your selection in step 1.

3. Set the **Max Volume** or **Max Volume Change** value.

   a. If you have chosen to adapt based on volume **Magnitude**, cells that have volumes greater than **Max Volume** will be marked or refined.

   b. If you are adapting based on volume **Change**, cells with volume changes greater than **Max Volume Change** will be marked or refined.

4. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).

5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated, as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the refinement immediately.

29.8. Yplus/Ystar Adaption

This section describes how to perform Yplus/Ystar adaption. For more information, see Yplus/Ystar Adaption in the Theory Guide.

For additional information, see the following section:
29.8.1. Performing Yplus or Ystar Adaption

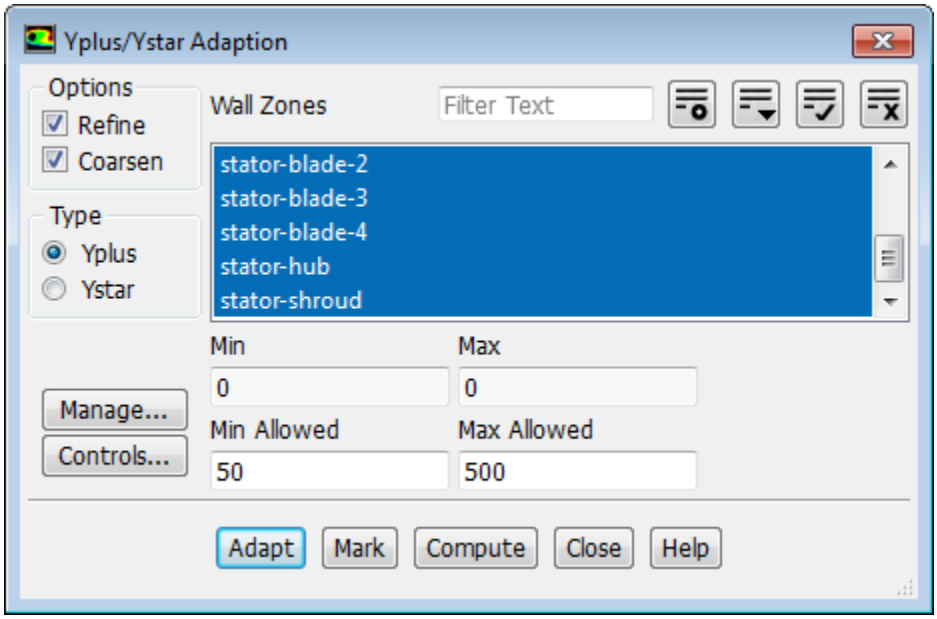
29.8.1. Performing Yplus or Ystar Adaption

You will perform Yplus or Ystar adaption in the Yplus/Ystar Adaption Dialog Box (p. 2842) (Figure 29.8: The Yplus/Ystar Adaption Dialog Box (p. 1696)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Yplus/Ystar...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 29.8: The Yplus/Ystar Adaption Dialog Box



The procedure for performing y^+ or y^* adaption is as follows:

1. In the Yplus/Ystar Adaption Dialog Box (p. 2842), select **Yplus** or **Ystar** as the adaption **Type**.
   - Select **Yplus** if you are using a y^+-insensitive wall treatment.
   - If you are using wall functions, you can select either type.
2. Select the wall zones for which you want boundary cells to be marked or adapted in the **Wall Zones** list, and click **Compute** to update the **Min** and **Max** fields. The values displayed are the minimum and maximum values for all wall zones, not just of those selected.
3. Set the **Min Allowed** and **Max Allowed**. Cells with y^+ or y^* values below **Min Allowed** will be coarsened or marked for coarsening, and cells with y^+ or y^* values above **Max Allowed** will be refined or marked for refinement.
4. (optional) If you want to set any adaption options (described in Mesh Adaption Controls Dialog Box (p. 2730)), click the **Controls...** button to open the Mesh Adaption Controls Dialog Box (p. 2730).
5. Click **Mark** to mark the cells for adaption (refinement/coarsening) by placing them in an adaption register (which can be manipulated as described in Manipulating Adaption Registers (p. 1701)), or click **Adapt** to perform the adaption immediately.

To disable refinement or coarsening, or marking for refinement or coarsening, turn off the **Refine** or **Coarsen** option before marking or adapting.

Note

y^+ and y^* values are only available for cells with faces on the wall.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.9. Anisotropic Adaption

This section describes how to perform anisotropic adaption. For more information, see Anisotropic Adaption in the Theory Guide.

For additional information, see the following sections:

29.9.1. Limitations of Anisotropic Adaption
29.9.2. Performing Anisotropic Adaption
29.9.3. Boundary Layer Redistribution

29.9.1. Limitations of Anisotropic Adaption

Since anisotropic adaption is available only for specific cell types, the following limitations exist:

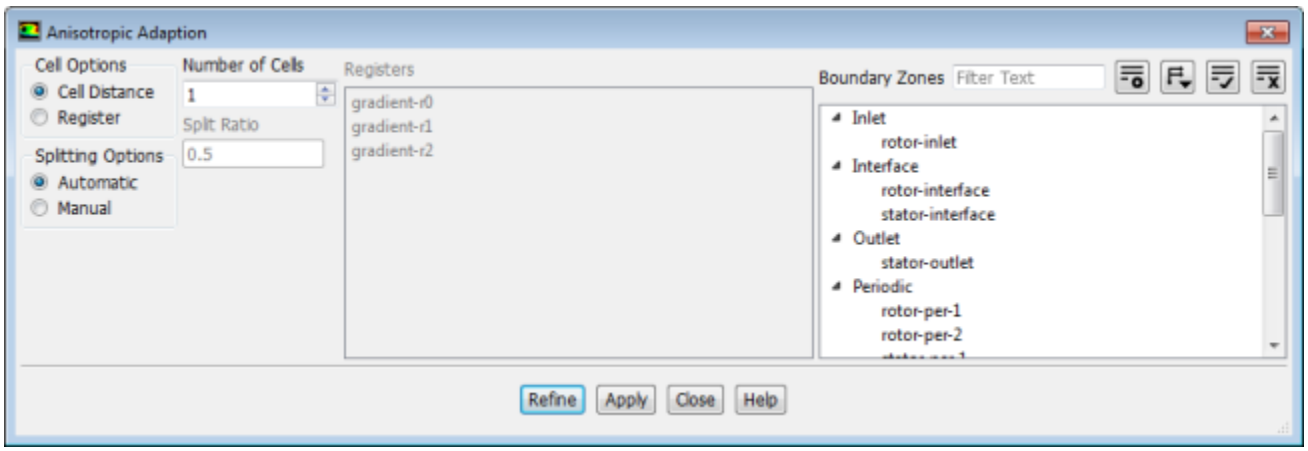
- It is only available in 3D.
- It only works for hexahedral cells or prism cells.
- Each cell can only be split into two, with a given splitting ratio in the normal direction of the boundary face. Multiple layers can be achieved by multiple refinement.
- Each cell to be split can only be reached once from any of the boundary faces; otherwise, the refinement will not be processed.
- Unlike other adaption functionalities, the subdivided cells cannot be coarsened again, because all the cells that are adjacent to the refined cells are converted into polyhedral cells.

29.9.2. Performing Anisotropic Adaption

You will perform anisotropic adaption in the Anisotropic Adaption Dialog Box (p. 2671) (Figure 29.9: The Anisotropic Adaption Dialog Box (p. 1697)).

Setting Up Domain → Adapt → Mark/Adapt Cells → Anisotropic...

Figure 29.9: The Anisotropic Adaption Dialog Box



The procedure for performing anisotropic adaption is as follows:

1. In the Anisotropic Adaption Dialog Box (p. 2671), select **Cell Distance** or **Register** from the **Cell Options** group box. This allows you to control the marking of boundary layer cells. Select **Cell Distance** and enter

the **Number of Cells** to be adapted and marked using the distance from the boundary zone. Select **Register** to adapt and mark cells using an existing **Register**.

2. The **Splitting Options** control how the splitting ratio is computed. It is defined as follows:

$$\text{splitting ratio} = \frac{\text{height of the splitting point to the base face}}{\text{original height of the cell}}$$

By default, **Automatic** is selected, resulting in the ratio being computed automatically from the mesh. If you selected **Manual**, enter the desired **Split Ratio**. If you choose to compute the split ratio automatically, the split ratio of the first layer is computed, and it may be 0.5 if the original cells are uniformly distributed, resulting in the height of the first layer being the same as the height of the second layer.

Important

Note that the **Split Ratio** that you enter is only applicable to the first layer, and all the other layers are split with a ratio of 0.5.

---

3. For the **Cell Distance** option, one or more boundary face zones must be selected before marking the cells for refinement.

4. For the **Register** option, select a register in the list. Note that one or more boundary face zones must be selected before doing the refinement.

5. Click **Refine** to refine the marked cells.

29.9.3. Boundary Layer Redistribution

After performing anisotropic adaption the boundary layer zone will generally not satisfy the original growth rate. To restore the desired growth rate you can use the `mesh/redistribute-boundary-layer` TUI command. You will be prompted to enter a face zone and the desired growth rate. The face zone you specify must be adjacent to the boundary layer zone that you want to redistribute.

```
>  mesh redistribute-boundary-layer
face zone id/name [] wall-fluid
growth rate [1.1] 1.2
```

Fluent will redistribute the nodes in a boundary region that extends into the mesh from the face zone you specify until one of the following criteria is encountered:

- the edge of the domain
- a change in zone
- a change in element type

As with anisotropic adaption itself, boundary layer redistribution is only available in 3D problems.

29.10. Geometry-Based Adaption

This section describes how to perform geometry-based adaption. For more information, see Geometry-Based Adaption in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

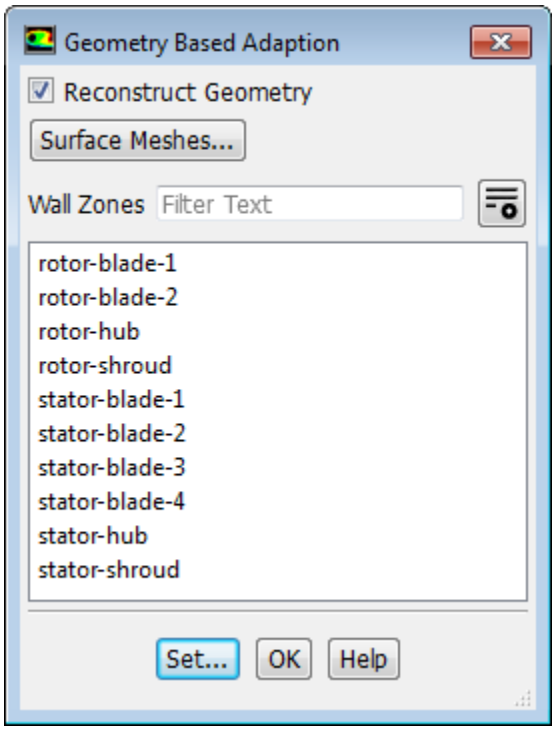
For additional information, see the following section:
29.10.1. Performing Geometry-Based Adaption

29.10.1. Performing Geometry-Based Adaption

The Geometry Based Adaption Dialog Box (p. 2709) (Figure 29.10: The Geometry Based Adaption Dialog Box (p. 1699)) allows you to reconstruct the geometry while performing boundary adaption.

Setting Up Domain → Adapt → More → Geometry...

Figure 29.10: The Geometry Based Adaption Dialog Box

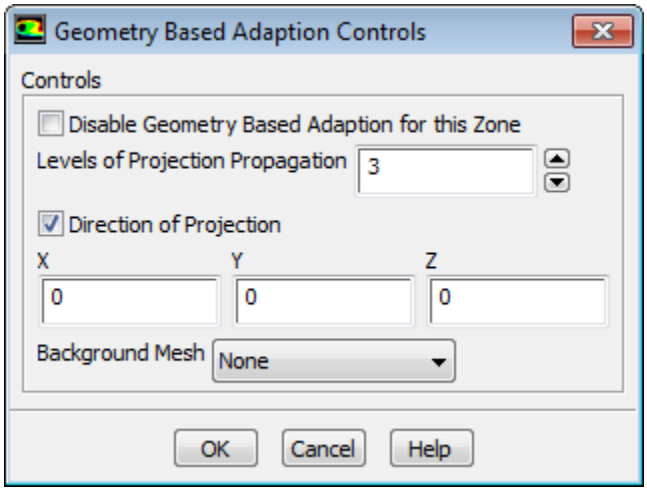


The procedure for performing geometry-based adaption is as follows:

1. Enable the **Reconstruct Geometry** option.
2. Under **Wall Zones**, select the zone you want to adapt and click **Set...**. The Geometry Based Adaption Controls Dialog Box (p. 2709) will open.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 29.11: The Geometry Based Adaption Controls Dialog Box



In the Geometry Based Adaption Controls Dialog Box (p. 2709), set the following parameters:

- Specify **Levels of Projection Propagation** to indicate the number of layers of the nodes you want to project.
- Enable **Direction of Projection** and specify the directions in which you want to project the nodes.

  This will make the **X** *,* **Y** *, and* **Z** *fields available. If you want node projection in the X direction, enter* 1 *for* **X** *. If you do not enable this option, the node projection will take place at the nearest point.*
- (optional) If you have a fine surface mesh for the geometry, you can use the **Background Mesh** option to load the surface mesh as a background mesh. This will project the nodes based on the background mesh and reconstruct the geometry more accurately.
- To disable the geometry reconstruction for any zone in the domain, enable the **Disable Geometry Based Adaption for this Zone** option.

3. To disable geometry-based adaption for the whole domain, disable **Reconstruct Geometry**.

   After setting the parameters for geometry-based adaption, proceed to perform mesh adaption.

29.11. Registers

This section describes how to use registers for adaption. For more information, see Registers in the Theory Guide.

Note

Similar to adaption registers, you can create cell registers, which are saved with the case file. For additional information on cell registers, see Creating Surfaces and Cell Registers for Displaying and Reporting Data (p. 1709) and Using Cell Registers (p. 1736).

For additional information, see the following sections:

29.11.1. Manipulating Adaption Registers
29.11.2. Modifying Adaption Marks
29.11.3. Displaying Registers

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.11.4. Adapting to Registers

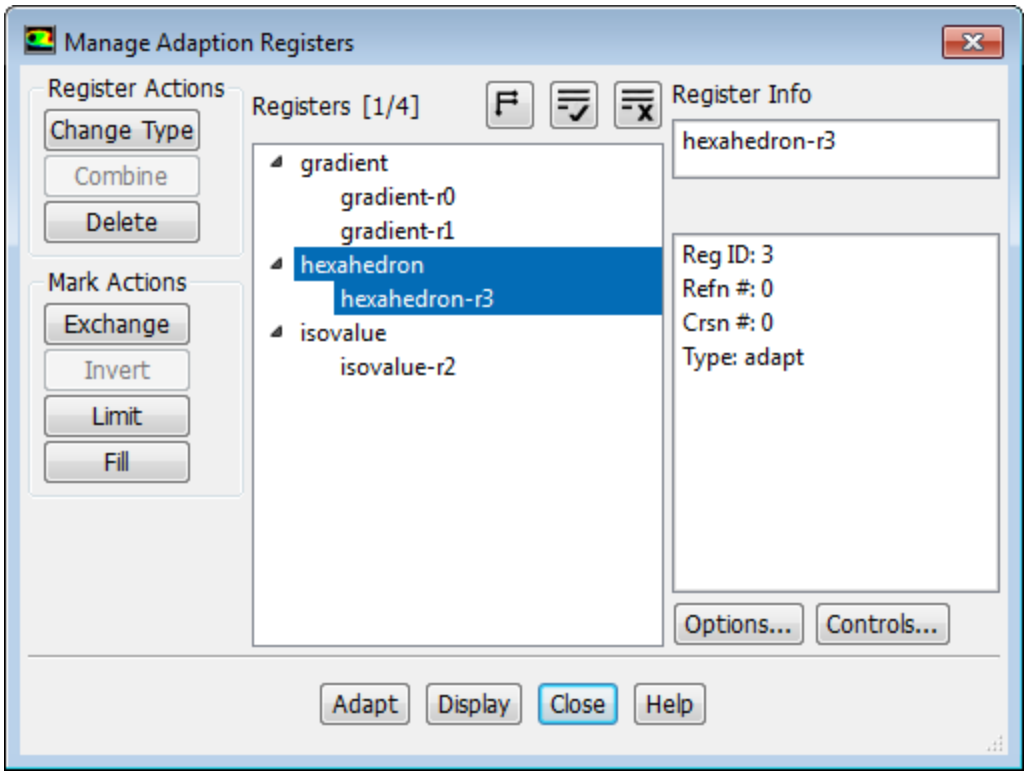
29.11.1. Manipulating Adaption Registers

You can manipulate, delete, and display adaption registers by marking cells for adaption. Since these registers are used to adapt the mesh, the ability to manipulate them provides additional control over the adaption process.

Management of adaption registers is performed in the Manage Adaption Registers Dialog Box (p. 2728) (Figure 29.12: The Manage Adaption Registers Dialog Box (p. 1701)). You can also open this dialog box by clicking on the **Manage...** button in any of the adaption dialog boxes.

Setting Up Domain → Adapt → Manage Registers...

Figure 29.12: The Manage Adaption Registers Dialog Box



You can modify and manipulate adaption registers by:

- changing the register types
- combining the registers
- deleting the registers

29.11.1.1. Changing Register Types

If the adaption register is converted to a mask, the cells marked for refinement are ACTIVE, and all other cells are INACTIVE (that is, the cells marked for coarsening are ignored). Generally, the adaption registers converted to masks are those that are generated by adaption functions that mark cells exclusively for refinement, such as region or isovalue adaption functions. The other major difference between adaption and mask registers is the manner in which they are combined.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To change the type of one or more registers from adaption to mask, or vice versa, do the following:

1. Choose the register(s) in the **Registers** list.

2. Click the **Change Type** button under **Register Actions**.

The new type of the register (if multiple registers are selected, the most recently selected or deselected register) will be shown as the **Type** under **Register Info**. Select each register individually to see what its current type is.

29.11.1.2. Combining Registers

After the individual adaption registers have been created and appropriately modified, they are combined to create hybrid adaption functions.

1. Any number of registers can be combined in the following manner:

   - All adaption registers are combined into a new adaption register.

   - All mask registers are combined into a new mask register.

   - The new adaption and mask registers are combined.

2. Any number of adaption registers can be combined in the following manner:

   - If the cell is marked for refinement in any of the registers, mark the cell for refinement in the new register (bitwise OR).

   - If the cell is marked for coarsening in all of the registers, mark the cell for coarsening in the new register (bitwise AND).

3. The mask registers are combined in a manner similar to the refinement marks. If any cell is marked ACTIVE, the cell in the new register is marked ACTIVE (bitwise OR).

4. Finally, in the combination of an adaption and mask register, only cells that are marked in the mask register can have an adaption mark in the combined register (bitwise AND).

For example, creating an adaption function based on pressure gradient may generate cells marked for refinement and coarsening throughout the entire solution domain. If this register is then combined with a mask register created from cells marked inside a sphere, only the cells inside the sphere will be marked for refinement or coarsening in the new register.

Note

The effect of masks depends on the order in which they are applied.

For example, consider two adjacent, circular masks. Applying one mask to the adaption register and then applying the other mask to the result of the first combination would give a much different result than applying the combination of the two masks to the initial adaption register. The second combination results in a greater possible number of marked cells.

To combine two or more registers, do the following:

1. Choose the registers in the **Registers** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the **Combine** button under **Register Actions**.

The selected registers will remain intact, and the register(s) resulting from the combination will be added to the **Registers** list. In some instances, three new registers may be created:

- a combination of the adaption registers
- a combination of the mask registers
- a combination of the two combined registers

For more information about combining registers, see Adaption Registers in the Theory Guide.

29.11.1.3. Deleting Registers

The primary reason for deleting registers is to discard unwanted adaption registers. This will reduce confusion and the possibility of generating undesired results by selecting these discarded registers. In addition, only 32 adaption registers can exist at one time. Therefore, you should discard unwanted registers to make room for new ones. You can delete any number of adaption registers.

To permanently delete one or more registers, do the following:

1. Choose the register(s) in the **Registers** list.
2. Click the **Delete** button under **Register Actions**.

29.11.2. Modifying Adaption Marks

The adaption marks are the identifiers that designate whether a cell should be refined, coarsened, or neutral. The operations used for modifying the adaption marks are:

- **Exchange**: This changes the cells marked for refinement into cells marked for coarsening, and all cells originally marked for coarsening into cells marked for refinement. This operation is applied to adaption registers that have only refinement marks.

  For example, the exchange operation can be used to coarsen a rectangular region. First, create an adaption register that marks a rectangular region of cells for refinement. Then use the **Exchange** operation to modify the cell marks, creating a rectangular region with cells marked for coarsening.

- **Invert**: This operation can only be used with mask registers. It toggles the mask markings, that is, all cells marked ACTIVE are switched to INACTIVE, and all cells marked INACTIVE are switched to ACTIVE.

  For example, if you generate a mask that defines a circular region, you can quickly modify the mask to define the region outside of the circle using the **Invert** operation.

- **Limit**: This operation applies the present adaption volume limit to the selected adaption register. For information on adaption limits, see Mesh Adaption Controls (p. 1705). You generally use this operation to determine the effect of the present limits on the adaption process. You can use the volume limit to create a uniform mesh by setting the limit to refine only the large cells. After all the cells have reached a uniform size, you can continue the refinement process to the desired resolution.

- **Fill**: This operation marks the cells in the adaption register that are not marked for refinement. You can use the **Fill** operation to combine multiple registers to make a new register.

  Note the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– When you combine registers, a cell will be marked for coarsening only if it is marked for coarsening in all of the registers.

– If you create an adaption register with an operation that only marks cells for refinement, but you do not want to prohibit coarsening, use the **Fill** operation before combining the register with any other registers.

The process for modifying adaption marks is as follows:

1. Choose the register(s) in the **Registers** list.

2. Click the **Exchange**, **Invert**, **Limit**, or **Fill** button under **Mark Actions**.

29.11.3. Displaying Registers

Viewing the cell markings is often helpful in the process of creating hybrid adaption functions. You can plot a marker at the cell centroid and/or a wireframe of the cell to view the state of the cell. By default, the cells marked for refinement are colored in red, and the cells marked for coarsening are marked in cyan. In addition, cells marked ACTIVE in a mask register are also colored red. These are the cells that are marked for adaption, but the final number of cells added or subtracted from the mesh depends on the adaption limits and the mesh characteristics.

To display a register, do the following:

1. Choose the register in the **Registers** list.

2. Set the display options by clicking on the **Options...** button.

3. Click the **Display** button.

29.11.3.1. Adaption Display Options

Various aspects of the adaption register display can be modified, such as the wireframe visibility and shading, marker visibility, color, size, and symbol. Also, you can select either surface or zone meshes for the display.

The adaption register display capability allows you to view the cells that are flagged for adaption.

- Depending on the dimension of the problem and the number of flagged cells, you can customize the adaption display options. The most common method for viewing flagged cells in 2D is to draw the mesh and filled wireframes, but this is impractical in 3D. In three dimensions, you can plot the centroid markers of the cells with the mesh of selected boundary zones.

- You can use markers and/or wireframes to display the flagged cells in an adaption or mask register. The marker is a symbol placed at the centroid of the cell. There is a refine marker and a coarsen marker. You can change the symbol, color, and size of these markers. A wireframe is composed of the edges of the triangle or tetrahedron. Its color is the same as the respective marker color, and can be filled, if required.

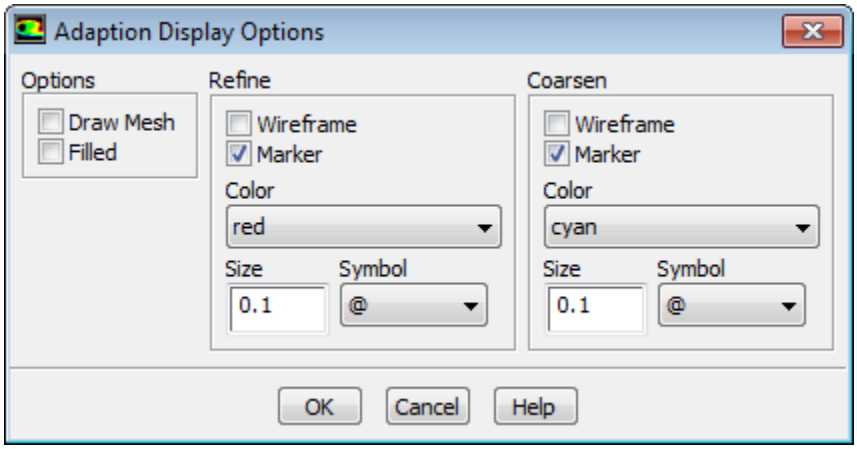
- Portions of the mesh can be drawn with the marker symbols or wireframes to aid in evaluating the location of marked cells.

All of these options are set in the Adaption Display Options Dialog Box (p. 2663) (Figure 29.13: The Adaption Display Options Dialog Box (p. 1705)). You can also open this dialog box by clicking on the **Options...** button in the Manage Adaption Registers Dialog Box (p. 2728).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Up Domain → Adapt → More → Display Options...

Figure 29.13: The Adaption Display Options Dialog Box



- To enable or disable the display of wireframes for cells marked for refinement/coarsening, turn the **Wireframe** option on or off under **Refine** and/or **Coarsen**. To draw filled wireframes (that is, using a solid color, instead of the outline) turn on the **Filled** option.
- To enable or disable the display of markers for cells marked for refinement/coarsening, turn the **Marker** option on or off under **Refine** and/or **Coarsen**. Use markers to specify their size in the **Size** field, and their symbol in the **Symbol** drop-down list.
- To change the color of the refine or coarsen markers/wireframes, select a new color in the **Color** drop-down list under **Refine** or **Coarsen**. By default, refine markers/wireframes are red and coarsen markers/wireframes are cyan.
- To include portions of the mesh in the register display, enable the **Draw Mesh** option. The Mesh Display Dialog Box (p. 2163) will open automatically, where you can set the mesh display parameters. When you click **Display** in the Manage Adaption Registers Dialog Box (p. 2728), the mesh display, as defined in the Mesh Display Dialog Box (p. 2163), will be included in the register display.

29.11.4. Adapting to Registers

These register tools provide you with the ability to create hybrid adaption functions customized to your flow-field application. The customized adaption function is used to direct the refinement and coarsening of the mesh.

To perform the adaption, follow these steps:

1. Choose the register in the **Registers** list.
2. Click the **Adapt** button.

29.12. Mesh Adaption Controls

ANSYS Fluent allows you to:

- Place restrictions on the cell zones.
- Limit adaption by cell volume or volume weight.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

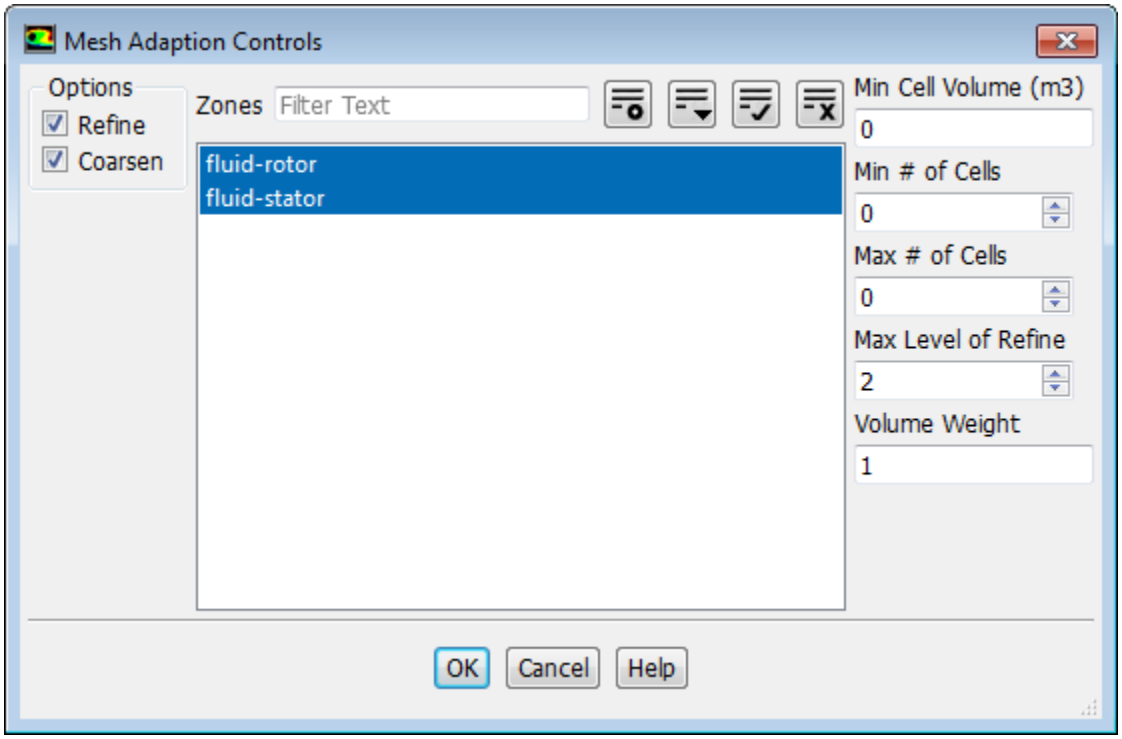
- Limit the total number of cells that can be produced from the adaption process.
- Modify the intensity of the volume weighting in the gradient function.
- Restrict the adaption process to refinement and/or coarsening, and control which nodes are eligible for possible elimination from the mesh during coarsening.

The parameters controlling the aspects of adaption are set in the Mesh Adaption Controls Dialog Box (p. 2730) (Figure 29.14: The Mesh Adaption Controls Dialog Box (p. 1706)).

You can open this dialog box by selecting **Controls...** from the **More** drop-down list in the **Setting Up Domain** tab (**Adapt** group box).

Setting Up Domain → Adapt → More → Controls...

Figure 29.14: The Mesh Adaption Controls Dialog Box



Note

Write a case and data file before starting the adaption process. Then, if you generate an undesirable mesh, you can restart the process with the saved files.

For additional information, see the following sections:

29.12.1. Limiting Adaption by Zone
29.12.2. Limiting Adaption by Cell Volume or Volume Weight
29.12.3. Limiting the Total Number of Cells
29.12.4. Controlling the Levels of Refinement During Hanging Node Adaption

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.12.1. Limiting Adaption by Zone

You can limit the adaption process to specified cell zones. The cells composing the fluid and solid regions of the analysis generally have very different resolution requirements and error indicators. Limiting the adaption to a specific cell zone and use different adaption functions to create the optimal mesh.

To limit the adaption to a particular cell zone (or to particular cell zones), select the cell zones in which you want to perform adaption in the **Zones** list. By default, adaption will be performed in all cell zones.

29.12.2. Limiting Adaption by Cell Volume or Volume Weight

The minimum cell volume limit restricts the refinement process to cells with volumes greater than the limit. Use this to initiate the refinement process on larger cells, gradually reducing the limit to create a uniform cell size distribution. Set this limit in the **Min Cell Volume** field. The input that you will give in this field for a 2D axisymmetric problem will be interpreted as the minimum cell area.

In addition, the gradient volume weight can be modified. A value of zero eliminates volume weighting, a value of unity uses the entire volume, and values between 0 and 1 scale the volume weighting. Set this value in the **Volume Weight** field. For more information, see Gradient Adaption Approach in the Theory Guide.

29.12.3. Limiting the Total Number of Cells

The maximum number of cells is a restriction that prevents ANSYS Fluent from creating more cells than required for the present analysis. In addition, it saves the time you would spend waiting for the mesh adaption process to complete the creation of these cells. However, this premature termination of the refinement process can produce undesirable mesh quality depending on the order in which the cells were visited, which is based on the cell arrangement in memory (random).

During the dynamic gradient adaption, the resulting number of cells after adaption is estimated. If this number exceeds the maximum number of cells, both the **Coarsen Threshold** and the **Refine Threshold** are updated. This is done to ensure the best possible mesh resolution with the specified number of cells. You can also specify the minimum number of cells. This is helpful if strong structures of the flow that were resolved with the adaption vanished (for example, left the domain) and you want to resolve the remaining weaker ones. This would otherwise require modifying the **Coarsen Threshold** and the **Refine Threshold**.

You can set the total number of cells allowed in the mesh in the **Max # of Cells** field. The minimum number of cells in the mesh can be set in the **Min # of Cells** field. The default values of zero places no limits on the number of cells.

Note

When using the parallel solver, the **Min # of Cells** and **Max # of Cells** values are not strictly obeyed, but provide an approximate limit to the minimum and maximum cell counts that the adaption algorithm will allow.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29.12.4. Controlling the Levels of Refinement During Hanging Node Adaption

You can control the number of levels of refinement used to split cells during nonconformal adaption by setting the **Max Level of Refine**. The default value of 2 is a good start for most problems. If this is not sufficient, you can increase this value.

Note

Even in a 2D problem, the default value of 2 can increase the number of cells by a factor of 16 in the adapted regions.

A value of zero leaves this parameter unbounded, and you should use a suitable limit for **Min Cell Volume**. For more information on hanging node adaption, see Hanging Node Adaption in the Theory Guide. For guidelines for limiting cell sizes and number of cells during dynamic gradient adaption, see Dynamic Gradient Adaption Approach (p. 1690).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 30: Creating Surfaces and Cell Registers for Displaying and Reporting Data

ANSYS Fluent enables you to select portions of the domain to be used for visualizing the flow field. The domain portions are called *surfaces*, and there are many ways to create them. Surfaces are required for graphical analysis of 3D problems because you cannot display vectors, contours, and so on, or create an XY plot for the entire domain at once. In 2D you can usually visualize the flow field on the entire domain, but to create an XY plot of a variable in a portion of the interior of the domain, you must generate a surface. In addition, in both 2D and 3D, you will need one or more surfaces if you want to generate a surface-integral report. Note that ANSYS Fluent will automatically create a surface for each boundary zone in the domain. Surface information is stored in the case file.

While you can create surfaces to visualize portions of the domain, you can create cell registers to visualize and perform operations on cell groupings. Similar to adaption registers (see Adapting the Mesh (p. 1681)), you can group cells by:

- Region
- Boundary
- Variable Limiter
- Field Variable
- Residuals
- Volume
- Yplus/Ystar

Cell registers are saved with the case file and can be used to display marked cells, adapt the mesh, apply poor mesh numerics, and report on the cells.

The following sections explain creating surfaces and cell registers:

30.1. Using Surfaces
30.2. Using Cell Registers

30.1. Using Surfaces

In order to visualize the internal flow of a 3D problem or create XY plots of solution variables for 3D results, you must select portions of the domain (surfaces) on which the data is to be displayed. Surfaces can also be used for visualizing or plotting data for 2D problems, and for generating surface-integral reports.

ANSYS Fluent provides methods for creating several kinds of surfaces, and stores all surfaces in the case file. These surfaces and their uses are described briefly below:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Zone Surfaces:

If you want to create a surface that will contain the same cells/faces as an existing cell/face zone, you can generate a zone surface. This kind of surface is useful for displaying results on boundaries.

Partition Surfaces:

When you are using the parallel version of ANSYS Fluent, you may find it useful to create surfaces that are defined by the boundaries between mesh partitions. You can then display data on each side of a partition boundary.

See Parallel Processing (p. 2009) for more information about running the parallel solver.

Point Surfaces:

To monitor the value of some variable or function at a particular location in the domain, you can create a surface consisting of a single point.

Line and Rake Surfaces:

To generate and display pathlines, you must specify a surface from which the particles are released. Line and rake surfaces are well-suited for this purpose and for obtaining data for comparison with wind tunnel data. A rake surface consists of a specified number of points equally spaced between two specified endpoints. A line surface is simply a line that includes the specified endpoints and extends through the domain; data points will be at the centers of the cells through which the line passes, and consequently will not be equally spaced.

Plane Surfaces:

If you want to display flow-field data on a specific plane in the domain, you can create a plane surface. A plane surface is simply a plane that passes through three specified points.

Quadric Surfaces:

To display data on a line (2D), plane (3D), circle (2D), sphere (3D), or quadric surface you can specify the surface by entering the coefficients of the quadric function that defines it. This feature provides you with an explicit method for defining surfaces.

Isosurfaces:

You can use an isosurface to display results on cells that have a constant value for a specified variable. Generating an isosurface based on x, y, or z coordinate, for example, will give you an x, y, or z cross-section of your domain. Generating an isosurface based on pressure will enable you to display data for another variable on a surface of constant pressure.

30.1.1. Zone Surfaces

Zone surfaces are useful for displaying results on boundaries. For example, you may want to plot contours of velocity magnitude at the inlet and outlet of the problem domain, or temperature contours on the domain's walls. To do so, you need to have a surface that contains the same faces (or cells) as an existing face (or cell) zone. Zone surfaces are created automatically for all boundary face zones in the domain, so you will generally not need to create any zone surfaces unless you accidentally delete one.

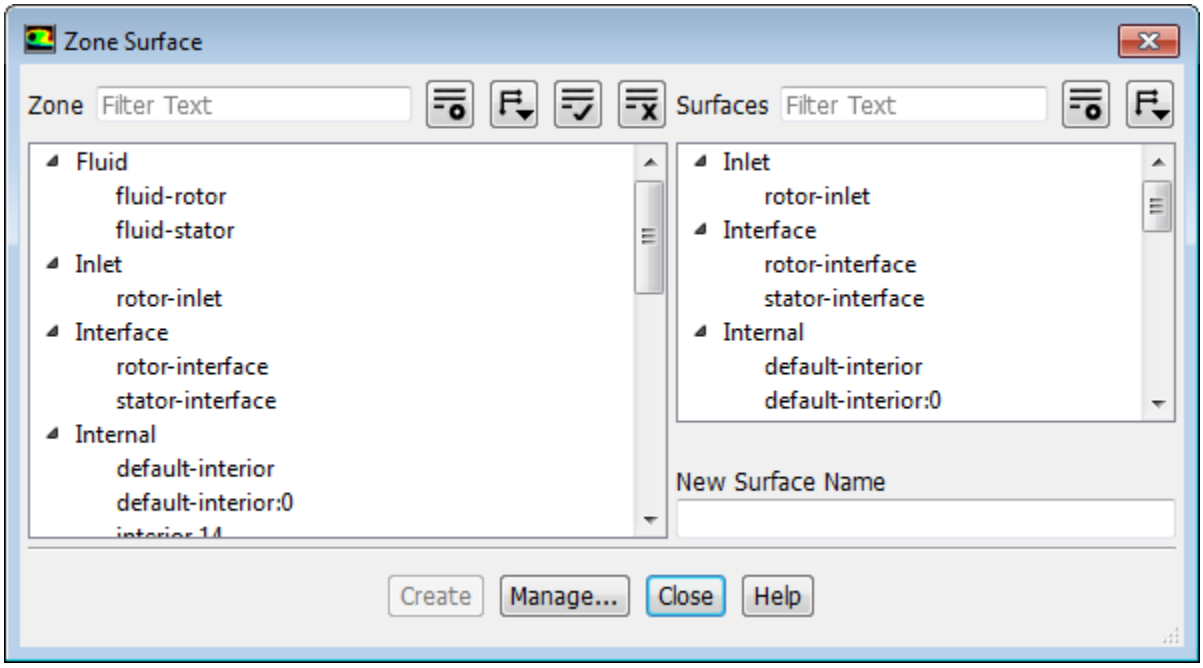
Use the text command: `surface/reset-zone-surfaces` to recreate any missing surface zones by resetting the case surface list.

To create a zone surface, you will use the Zone Surface Dialog Box (p. 2844) (Figure 30.1: The Zone Surface Dialog Box (p. 1711)).

Setting Up Domain → Surface → Create → Zone...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.1: The Zone Surface Dialog Box



The steps for creating the zone surface are as follows:

1. Select the zone(s) in the **Zone** list.

2. Enter a name in **New Surface Name** if you do not want ANSYS Fluent to assign a default name to the newly created surface. By default, Fluent assigns each surface the same name as the zone that it corresponds to. If a surface already exists with that name, Fluent assigns the surface a unique name using the `zone-surface` prefix (for example, `zone-surface-6`).

   If you do not want to use the default name, enter a new name in **New Surface Name**. If the **New Surface Name** that you enter is the same as a surface that already exists, Fluent assigns the new surface a unique name using the `zone-surface` prefix (for example, `zone-surface-7`).

   Important

   - The surface name that you enter must begin with an alphabetical letter. If your surface name begins with any other character or number, Fluent rejects the entry.
   - If you are selecting multiple zones, you do not have the option to choose the surface names. ANSYS Fluent automatically give the surfaces the same names as their corresponding zone.

3. Click **Create**. The new surface name is added to the **Surfaces** list in the dialog box.

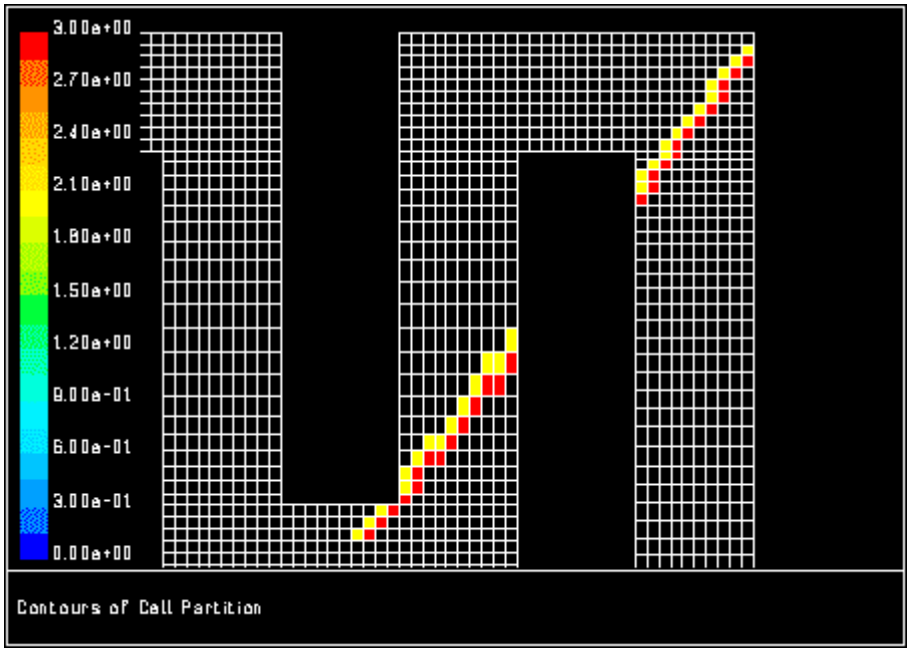
If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). For details, see Grouping, Renaming, and Deleting Surfaces (p. 1734).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

30.1.2. Partition Surfaces

If you are using the parallel version of ANSYS Fluent (see Parallel Processing (p. 2009)), you may find it useful to create data surfaces defined by the boundaries of mesh partitions. As described in Mesh Partitioning and Load Balancing (p. 2030), partitioning the mesh divides it into groups of cells that can be solved on separate processors when you use a parallel solver. A partition surface will contain faces or cells on the boundary of two mesh partitions. For example, you can plot solution values on the partition surface to determine how the solution is changing across a partition interface, as shown in the following figure:

Figure 30.2: Contours of Cell Partitions on Partition Surface Overlaid on Mesh

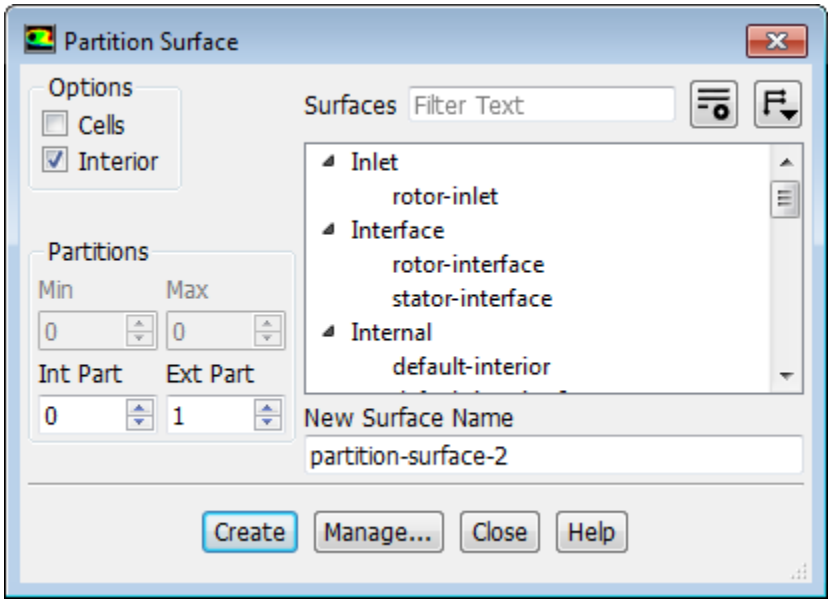


To create a partition surface, you will use the Partition Surface Dialog Box (p. 2766) (Figure 30.3: The Partition Surface Dialog Box (p. 1713)).

Setting Up Domain → Surface → Create → Partition...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.3: The Partition Surface Dialog Box



The procedure for creating the partition surface are as follows:

1. Specify the partition boundary in which you are interested by indicating the two bordering partitions under the **Partitions** heading. The boundary that defines the partition surface is the boundary between the "interior partition" and the "exterior partition". **Int Part** indicates the ID number of the interior partition (that is, the partition under consideration), and **Ext Part** indicates the ID number of the bordering (exterior) partition. The **Min** and **Max** fields will indicate the minimum and maximum ID numbers of the mesh partitions. The minimum is always zero, and the maximum is one less than the number of processors. If there are more than two mesh partitions, each interior partition will share boundaries with several exterior partitions. By setting the appropriate values for **Int Part** and **Ext Part**, you can create surfaces for any of these boundaries.

2. Choose interior or exterior faces or cells to be contained in the partition surface by selecting or clearing **Cells** and **Interior** under **Options**. To obtain a surface consisting of cells that are on the "interior" side of the partition boundary, select both **Cells** and **Interior**. To create one consisting of cells that are on the "exterior" side, select **Cells** and clear **Interior**. If you want the surface to contain the faces on the boundary instead of the cells, clear the **Cells** option. To have the faces reflect data values for the interior cells, select the **Interior** check box, and to have them reflect values for the exterior cells, clear it.

3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `partition-surface-6`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.)

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

4. Click **Create**. The new surface name is added to the **Surfaces** list in the dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). For details, see Grouping, Renaming, and Deleting Surfaces (p. 1734).

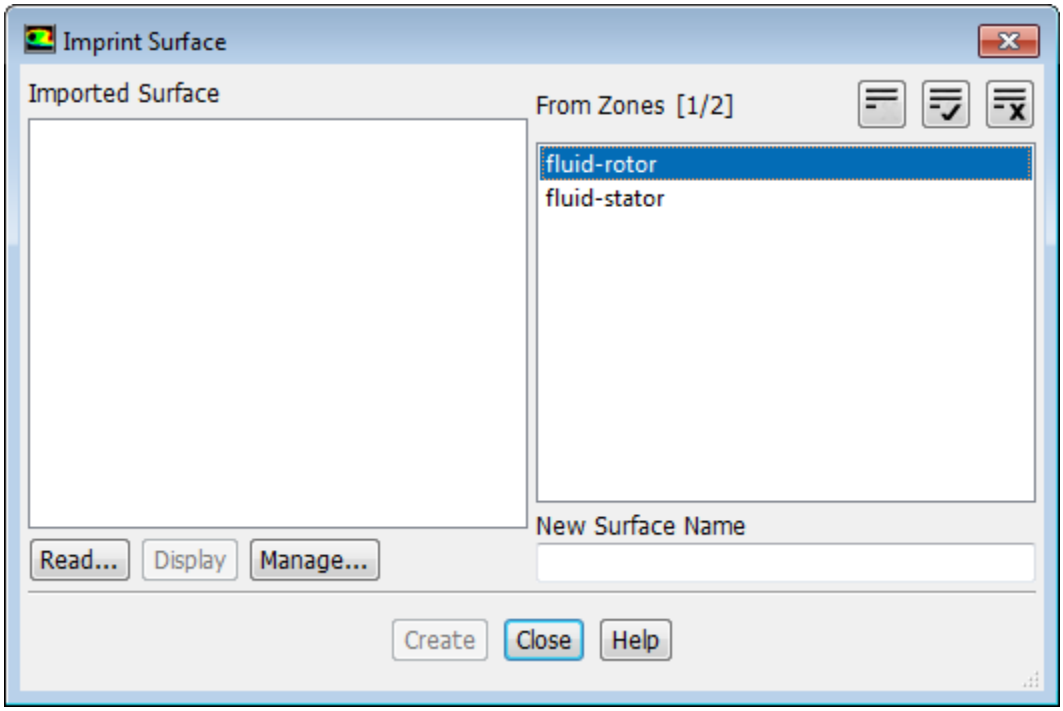
30.1.3. Imprint Surfaces

If you want to display results on surfaces that are more complicated than a simple point or plane, then you can import a custom surface representing the region of interest (`.stl` or `.msh` format) and "imprint" this surface into the current mesh. For example, you may want to visualize only a smaller custom portion of a much larger (complex) geometry.

To create an imprinted surface, use the Imprint Surface Dialog Box (p. 2714) (Figure 30.4: The Imprint Surface Dialog Box (p. 1714)).

Setting Up Domain → Surface → Create → Imprint...

Figure 30.4: The Imprint Surface Dialog Box



Create an imprinted surface as follows:

1. Click **Read** and select your geometry file (`.stl` or `.msh` format) using the **Select File** dialog box.

   Specify the units the mesh was created in (default is meters).

2. Click **OK** to upload your file.

   The name of your geometry file appears in the **Imported Surface** *dialog box.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select the zone where your geometry is located in the **From Zones** group box.

> **Note**
>
> If you do not specify a zone, Fluent uses the entire domain for imprinting. For a large mesh this could be time consuming.

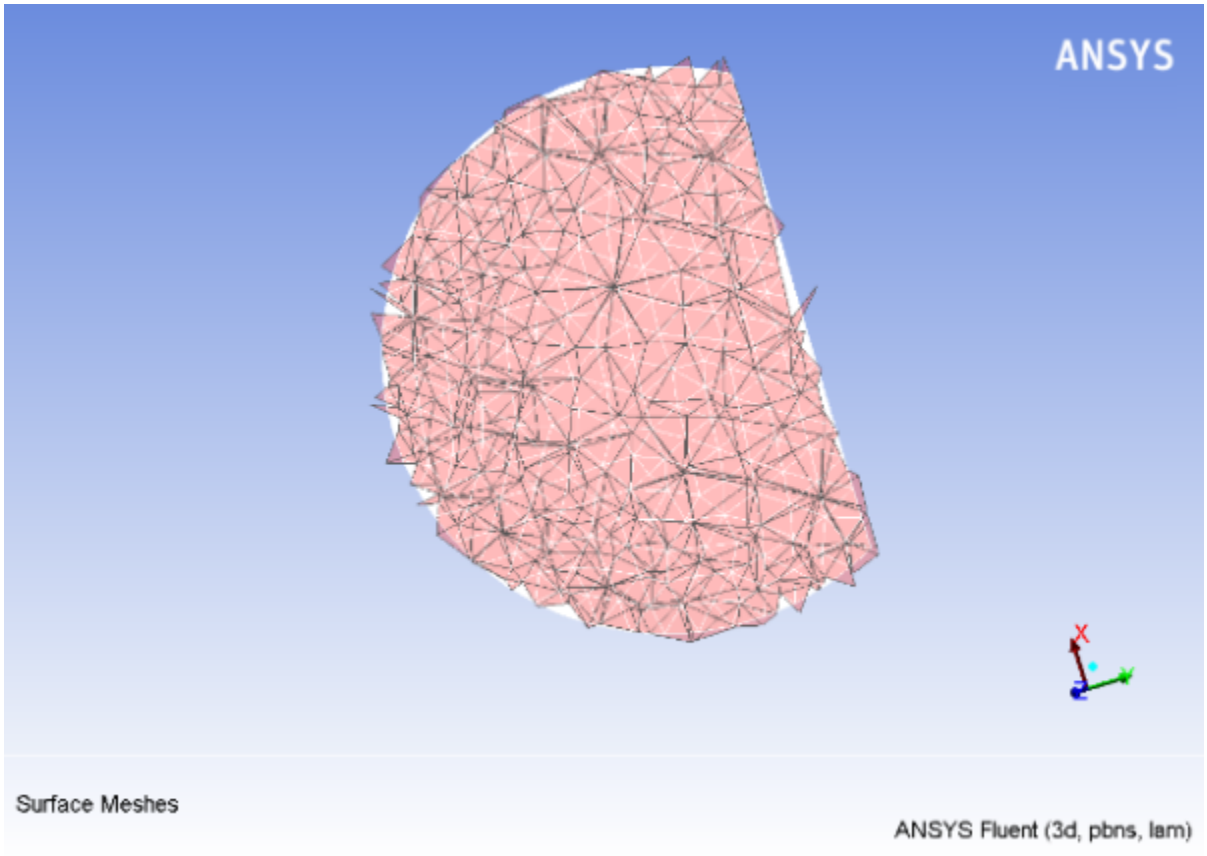
4. Enter a name for your new surface in the **New Surface Name** dialog box.

   The default name is `<orig-name>(imprint)<id>`.

5. Click **Create** to create the new surface.

When an imported surface is imprinted, a postprocessing surface that coincides with the imported surface is created. The imprinted surface will not have facets for the portions of the original surface that lie outside the domain. Different postprocessing operations such as contour and vector plots, and surface integrals can be performed on this surface. However, the edges of the imprinted surface may not coincide with those of the original surface, if the edges of the original surface do not coincide with mesh edges. An example is shown in the following picture.

Figure 30.5: Imprinted Surface (pink) Superimposed Over Imported Surface (white)



As you can see in Figure 30.5: Imprinted Surface (pink) Superimposed Over Imported Surface (white) (p. 1715), there are deformities around the edges of the imprinted surface.

Important

If you want to create an imprint surface from multiple disconnected source surfaces, it is better to create multiple imprint surfaces (one per source surface) and, if required, group them together after they are created. For information on grouping surfaces, see Grouping, Renaming, and Deleting Surfaces (p. 1734).

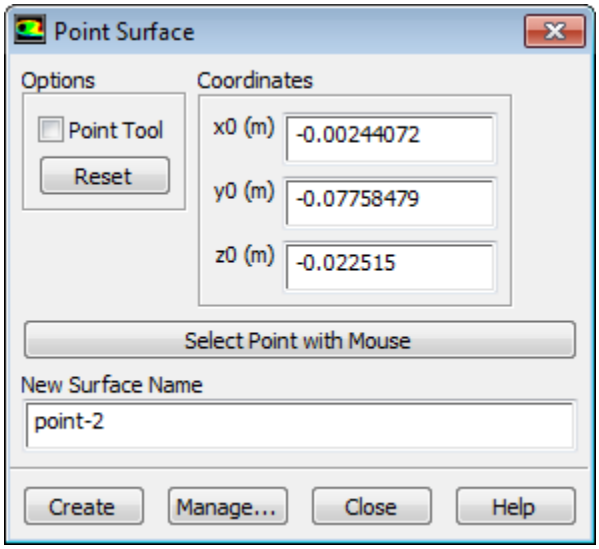
30.1.4. Point Surfaces

You may often be interested in displaying results at a single point in the domain. For example, you may want to monitor the value of some variable or function at a particular location. To do this, you must first create a "point" surface, which consists of a single point. When you display node-value data on a point surface, the value displayed is a linear average of the neighboring node values. If you display cell-value data, the value at the cell in which the point lies is displayed.

To create a point surface, use the Point Surface Dialog Box (p. 2780) (Figure 30.6: The Point Surface Dialog Box (p. 1716)).

Setting Up Domain → Surface → Create → Point...

Figure 30.6: The Point Surface Dialog Box



Create a point surface as follows:

1. Specify the location of the point. There are three different ways to do this:
   - Enter the coordinates (**x0, y0, z0**) under **Coordinates**.
   - Click **Select Point With Mouse** and then select the point by clicking on a location in the active graphics window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Use the **Point Tool** option to interactively position a point in the graphics window. You can set the initial location of this point using one of the two methods described above for specifying the point's position (or you can start from the position defined by the default **Coordinates**). See Using the Point Tool (p. 1717) for information about using the point tool.

2. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `point-5`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.)

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

3. Click **Create** to create the new surface.

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). For details, see Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.4.1. Using the Point Tool

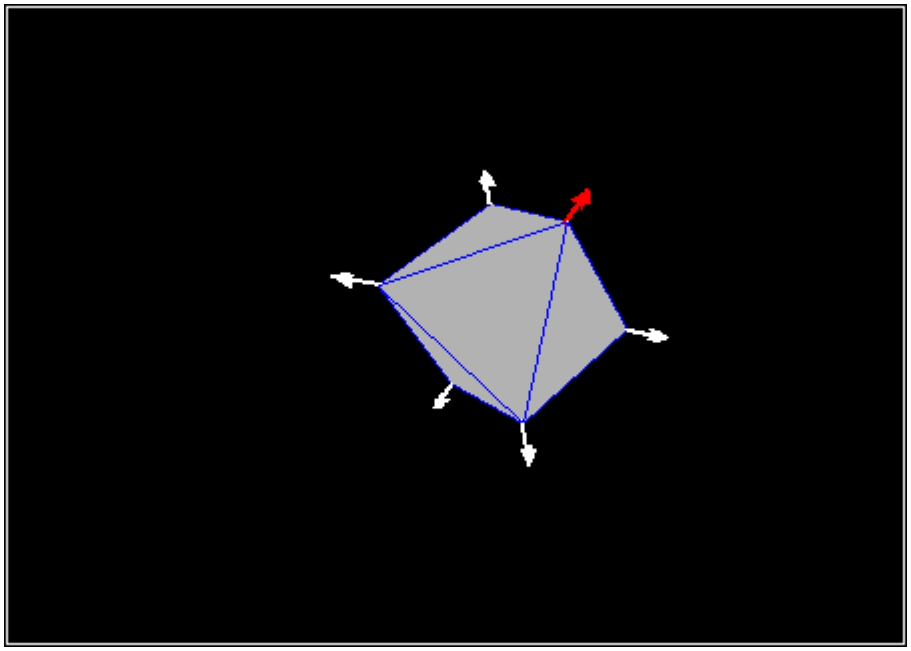
The point tool enables you to interactively fine-tune the definition of a point using graphics. Starting from an initial point, you can translate the point until its position is as desired. For example, if you need to position a point surface at the center of a duct, just past the inlet, you can start with the point tool near the desired location (such as on the inlet), and translate it until it is in the proper place. (You may find it helpful to display mesh faces to ensure that the point tool is correctly positioned inside the domain.)

30.1.4.1.1. Initializing the Point Tool

Before enabling the **Point Tool** option, set the **Coordinates** to suitable starting values. You can enter values manually, or use the **Select Point With Mouse** button. Often it is convenient to display the mesh for an inlet or isosurface on or near where the point is to be located, and then select a point on that mesh to specify the initial position of the point tool. Once you have specified the appropriate **Coordinates**, turn on the tool by enabling the **Point Tool** option. The point tool, an eight-sided polygon, will appear in the graphics window, as shown in Figure 30.7: The Point Tool (p. 1718).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.7: The Point Tool



You can then translate the point tool as described below. The point surface you create will be located at the center of the point tool.

30.1.4.1.2. Translating the Point Tool

To translate the point tool in the direction along the red axis, click the mouse-probe button (the right button by default) anywhere on the gray part of the point tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion. For information about changing the mouse functions, see Controlling the Mouse Button Functions (p. 1800).

To translate the tool in the transverse directions (that is, along either of the other axes), press **Shift**, click the mouse-probe button anywhere on the gray part of the point tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. In 2D, there will be only one set of green arrows because there is only one other direction for translation. If you find the perspective distracting when performing this type of translation, you can turn it off in the Camera Parameters Dialog Box (p. 2587) (opened from the Views Dialog Box (p. 2583)), as described in Controlling Perspective and Camera Parameters (p. 1808).

30.1.4.1.3. Resetting the Point Tool

If you "lose" the point tool, or want to reset it for any other reason, you can either click **Reset** to return the point tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the point tool will lie at the center of the domain.

30.1.5. Line and Rake Surfaces

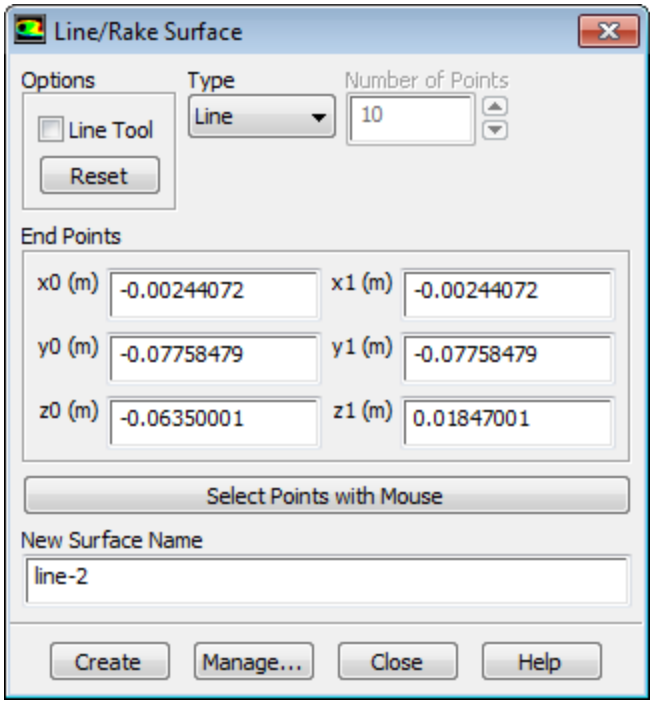
You can create lines and rakes in the domain for releasing particles, obtaining data for comparison with tunnel data, and so on. A rake consists of a specified number of points equally spaced between two specified endpoints. A line is simply a line that extends up to and includes the specified endpoints; data points will be located where the line intersects the faces of the cell, and consequently may not be equally spaced.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To create a line or rake surface, you will use the Line/Rake Surface Dialog Box (p. 2727) (Figure 30.8: The Line/Rake Surface Dialog Box (p. 1719)).

Setting Up Domain → Surface → Create → Line/Rake...

Figure 30.8: The Line/Rake Surface Dialog Box



The steps for creating the line or rake surface are as follows:

1. Indicate whether you are creating a **Line** surface or a **Rake** surface by selecting the appropriate item in the **Type** drop-down list.

2. If you are creating a rake surface, specify the **Number of Points** to be equally spaced between the two endpoints.

3. Specify the location of the line or rake surface. There are three different ways to define the location:

   - Enter the coordinates of the first point (**x0, y0, z0**) and the last point (**x1, y1, z1**) under **End Points**.

   - Click **Select Points With Mouse** and then select the endpoints by clicking on locations in the active graphics window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)

   - Use the **Line Tool** option to interactively position a line in the graphics window. You can set the initial location of this line using one of the two methods described above for specifying endpoints (or you can start from the position defined by the default **End Points**). See Using the Line Tool (p. 1720) for information about using the line tool.

   Note that when you use the second or third method described above, the coordinates of the **End Points** are updated automatically.

4. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ID (for example, `line-5` or `rake-6`). If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

5. Click **Create** to create the new surface.

If you want to check that the new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.5.1. Using the Line Tool

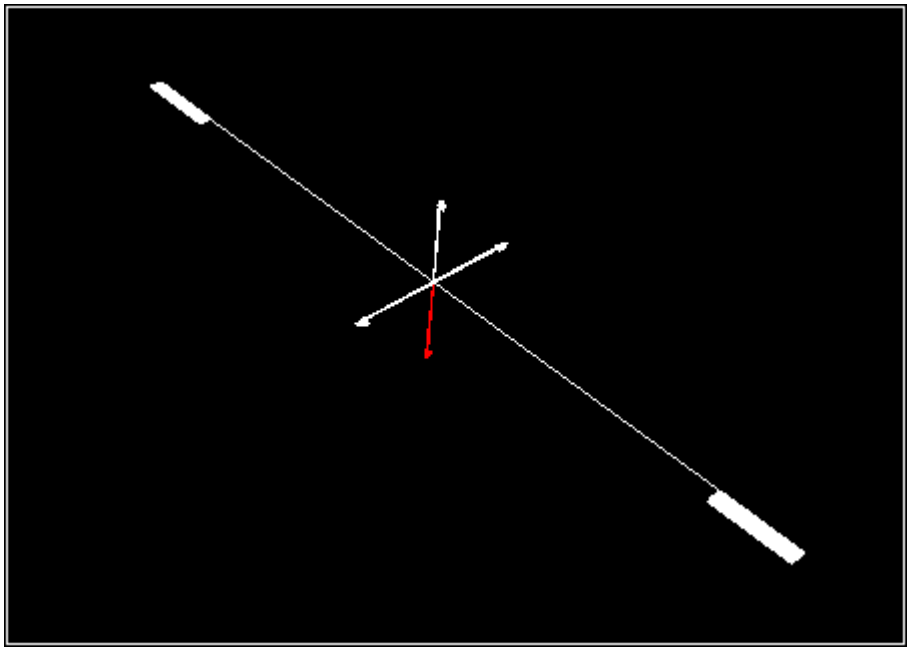
The line tool enables you to interactively fine-tune the definition of a line or rake using graphics. Starting from an initial line, you can translate, rotate, and resize the line until its position, orientation, and length are as desired. For example, if you need to position a rake surface just inside the inlet to a duct, you can start with the line tool near the desired location (such as on the inlet), and translate, rotate, and resize it until you are satisfied. You may find it helpful to display mesh faces to ensure that the line tool is correctly positioned inside the domain.

30.1.5.1.1. Initializing the Line Tool

Before enabling the **Line Tool** option, set the **End Points** to suitable starting values. You can enter values manually, or use the **Select Points With Mouse** button. Often it is convenient to display the mesh for an inlet or isosurface on or near where you want to place the line or rake surface and then select two points on that mesh to specify the initial position of the line tool. Once you have specified the appropriate **End Points**, enable the **Line Tool** option. The line tool appears in the graphics window, as shown in Figure 30.9: The Line Tool (p. 1721).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.9: The Line Tool



You can then translate, rotate, and/or resize the line tool as described in the following sections.

30.1.5.1.2. Translating the Line Tool

To translate the line tool in the direction along the red axis, click the mouse-probe button (the right button by default) anywhere on the "line" part of the tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion For information about changing the mouse functions see Controlling the Mouse Button Functions (p. 1800).

Important

Do not click the axes of the line tool that have arrows on the ends. These axes control rotation of the tool. Click only on the portion of the tool that represents the prospective line surface. This portion is designated by the rectangles attached to each end.

To translate the tool in the transverse directions (that is, along either of the axes within the plane perpendicular to the red axis), press **Shift**, click the mouse-probe button anywhere on the "line" part of the tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. In 2D, there will be only one set of green arrows because there is only one other direction for translation. If you find the perspective distracting when performing this type of translation, you can disable it in the Camera Parameters Dialog Box (p. 2587) (opened from the Views Dialog Box (p. 2583)), as described in Controlling Perspective and Camera Parameters (p. 1808).

30.1.5.1.3. Rotating the Line Tool

To rotate the line tool, you click the mouse-probe button on one of the white axes with arrows. When you click one of these axes, a green ribbon will encircle the other arrowed axis, designating it as the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

axis of rotation. As you drag the mouse along the circle to rotate the tool, the green circle will become yellow.

Important

Do not click the red axis to rotate the line tool.

30.1.5.1.4. Resizing the Line Tool

If you plan to generate a rake surface, you can resize the line tool to define the length of the rake. Click the mouse-probe button in one of the white rectangles at the ends of the "line" part of the tool (shown in black in Figure 30.9: The Line Tool (p. 1721)) and drag the mouse to lengthen or shorten the tool. Green arrows will show the direction of stretching/shrinking.

30.1.5.1.5. Resetting the Line Tool

If you "lose" the line tool, or want to reset it for any other reason, you can either click **Reset** to return the line tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the line tool will lie midway along the x and y lengths of the domain, spanning the z domain extent.

30.1.6. Plane Surfaces

To display flow-field data on a specific plane in the domain, you will use a plane surface. You can create surfaces that cut through the solution domain along arbitrary planes only in 3D; this feature is not available in 2D.

There are six types of plane surfaces that you can create:

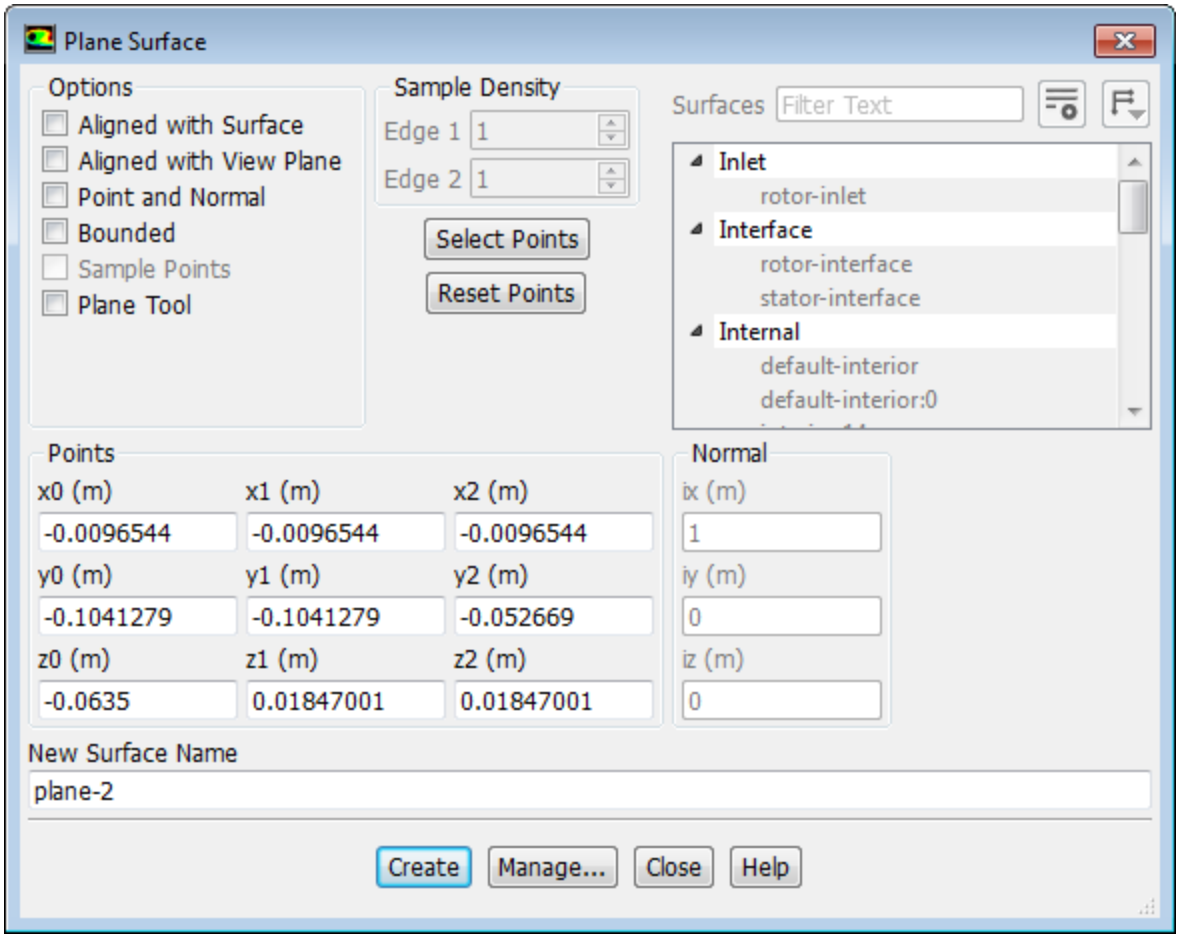
- Intersection of the domain with the infinite plane: This is the default plane surface created. The extents of the plane is determined by the extents of the domain. Because the plane is slicing through the domain, the data points will, by default, be located where the plane intersects the faces of a cell, and consequently may not be equally spaced.
- Bounded plane: This plane will be a bounded parallelepiped, for which 3 of the 4 corners are the 3 points that define the plane equation (or the 4 corners are the corners of the "plane tool"). Like the default plane surface described above, this type of surface will also have unequally spaced data points.
- Bounded plane with equally spaced data points: This plane is the same as the bounded plane described above, except you will specify the density of points along the two directions of the parallelepiped, creating a uniform distribution of data points.
- Plane having a certain normal vector and passing through a specified point: To create this type of plane, define a normal vector and a point. A plane with the specified normal and passing through the specified point will be created.
- Plane aligned with an existing surface: To create this type of plane, you will define a single point and a surface. A plane parallel to the selected surface and passing through the specified point will be created.
- Plane aligned with the view in the graphics window: To create this type of plane, you will define a single point. A plane parallel to the current view in the active graphics window and passing through the specified point will be created.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To create a plane surface, you will use the Plane Surface Dialog Box (p. 2777) (Figure 30.10: The Plane Surface Dialog Box (p. 1723)).

Setting Up Domain → Surface → Create → Plane...

Figure 30.10: The Plane Surface Dialog Box



The procedure for creating the plane surface is as follows:

1. Decide which of the six types of planes you want to create.

   - To create the default plane type (the intersection of the infinite plane with the domain), go directly to step 2.
   - To create a bounded plane, select **Bounded** under **Options**.
   - To create a bounded plane with equally spaced data points, select both **Bounded** and **Sample Points**, and then set the number of data points under **Sample Density**. You will specify the point density in each direction by entering the appropriate values for **Edge 1** and **Edge 2**. Edge 1 extends from point 0 to point 1, and edge 2 extends from point 1 to point 2.
   - To define a plane aligned with an existing surface, select **Aligned With Surface**, and then choose the surface in the **Surfaces** list and specify a single point using one of the first two methods described below in step 2.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To define a plane aligned with the view plane, select **Aligned With View Plane**, and then choose a single point using one of the first two methods described below in step 2.
- To define a plane having a certain normal vector and passing through a specified point, select **Point And Normal**, and then specify the normal vector by entering values in the **ix**, **iy**, and **iz** fields under **Normal**, and a single point using one of the first two methods described below in step 2.

2. Specify the location of the plane surface. There are three different ways to define the location:
   - Enter the coordinates of the three **Points** defining the planar surface: (**x0, y0, z0**), (**x1, y1, z1**), and (**x2, y2, z2**).
   - Click **Select Points** and then select the three points by clicking on locations in the active graphics window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)
   - Use the **Plane Tool** option to interactively position a plane in the graphics window. You can set the initial location of this plane using one of the two methods described above for specifying the defining points. You can also start from the position defined by the default **Points**. See Using the Plane Tool (p. 1724) for information about using the plane tool.

   Note that when you use the second or third method described above, the coordinates of the **End Points** are updated automatically.

3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `plane-7`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.)

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

4. Click **Create** to create the new surface.

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.6.1. Using the Plane Tool

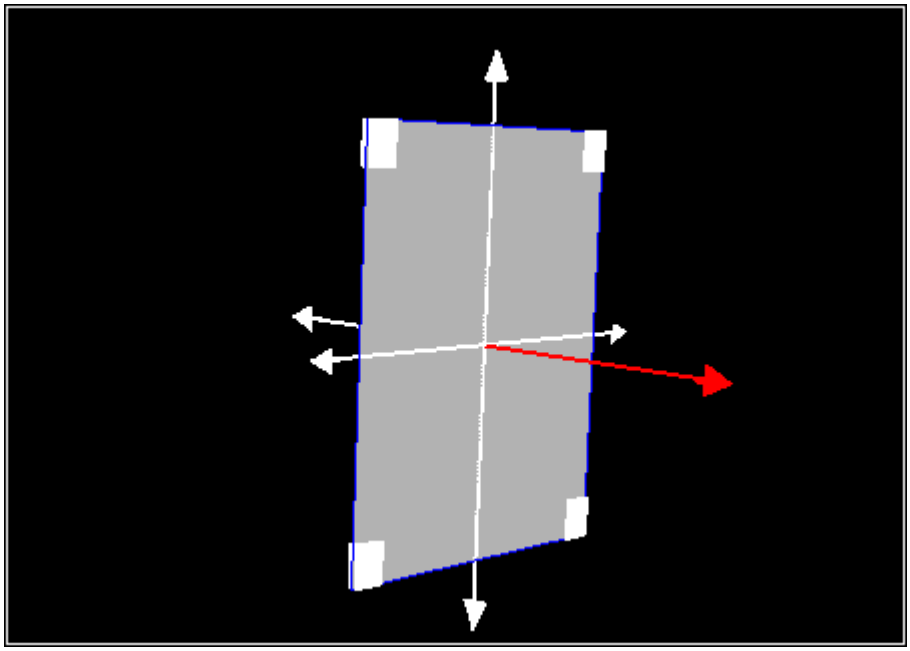
The plane tool enables you to interactively fine-tune the definition of a plane using graphics. Starting from an initial plane, you can translate, rotate, and resize the plane until its position, orientation, and size are as desired. For example, if you need to position a plane surface at a cross-section of an irregularly-shaped, curved duct, you can start with the plane tool near the desired location, resize it, translate it until it is within the duct walls, and rotate it to the proper orientation. You may find it helpful to display mesh faces to ensure that the plane tool is correctly positioned inside the domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

30.1.6.1.1. Initializing the Plane Tool

Before enabling the **Plane Tool** option, set the **Points** to suitable starting values. You can enter values manually, or use the **Select Points** button. Often it is convenient to display the mesh for an inlet or isosurface that is similar to the desired plane surface, and then select three points on that mesh to position the initial plane. Once you have specified the appropriate **Points**, enable the **Plane Tool** option. The plane tool will appear in the graphics window, as shown in Figure 30.11: The Plane Tool (p. 1725).

Figure 30.11: The Plane Tool



You can then translate, rotate, and/or resize the plane tool as described in the following sections.

30.1.6.1.2. Translating the Plane Tool

To translate the plane tool in the direction normal to the plane, click the mouse-probe button (the right button by default) anywhere on the gray part of the plane tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion. For information about changing the mouse functions see Controlling the Mouse Button Functions (p. 1800).

To translate the tool in the transverse directions (that is, along either of the axes that lie within the plane), press **Shift**, click the mouse-probe button anywhere on the gray part of the plane tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. If you find the perspective distracting when performing this type of translation, you can turn it off in the Camera Parameters Dialog Box (p. 2587) (opened from the Views Dialog Box (p. 2583)), as described in Controlling Perspective and Camera Parameters (p. 1808).

30.1.6.1.3. Rotating the Plane Tool

To rotate the plane tool, click the mouse-probe button on one of the white arrows at the tips of the plane's axes. Clicking on any arrow rotates the tool about either of the other two axes: when you click the arrow, two green ribbons will encircle the plane tool, forming circles about each of the two possible axes of rotation. Drag the mouse along the desired circle to rotate the tool. As you do so, the circle along which the tool is rotating will become yellow.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following notes may help you when you are rotating the plane tool:

- Once you move your mouse along one circle, you cannot change the direction of rotation unless you release the mouse-probe button and try again. Be careful to start moving your mouse very steadily so that you can choose the correct direction.
- Do not click the red arrow to rotate.
- Do not try to rotate by clicking on an arrow that is pointing away from you. It will be very difficult for you to judge which direction of rotation is correct from this point of view. Because there are two arrows on each axis, there will always be an appropriate arrow available.
- Do not rotate the plane tool more than 90° or so at once. If you rotate the tool by a large angle, the arrow on which you are clicking will begin to point away from you, and you will have trouble controlling the rotation (as discussed in the item above).

30.1.6.1.4. Resizing the Plane Tool

If you plan to generate a bounded plane, you can resize the plane tool to define the plane's boundaries. Click the mouse-probe button in one of the white squares at the plane tool's corners (shown in black in Figure 30.11: The Plane Tool (p. 1725)) and drag the mouse to stretch or shrink the tool. Green arrows will show the direction of the plane's diagonal.

Important

Be careful not to drag your mouse across any of the axes while resizing the tool. This will flip the tool over and corrupt it. If you accidentally do this, reset the plane tool and start again.

30.1.6.1.5. Resetting the Plane Tool

If you "lose" the plane tool, or want to reset it for any other reason, you can either click **Reset Points** to return the plane tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the plane tool will lie midway along the x length of the domain, spanning the y and z domain extents.

30.1.7. Quadric Surfaces

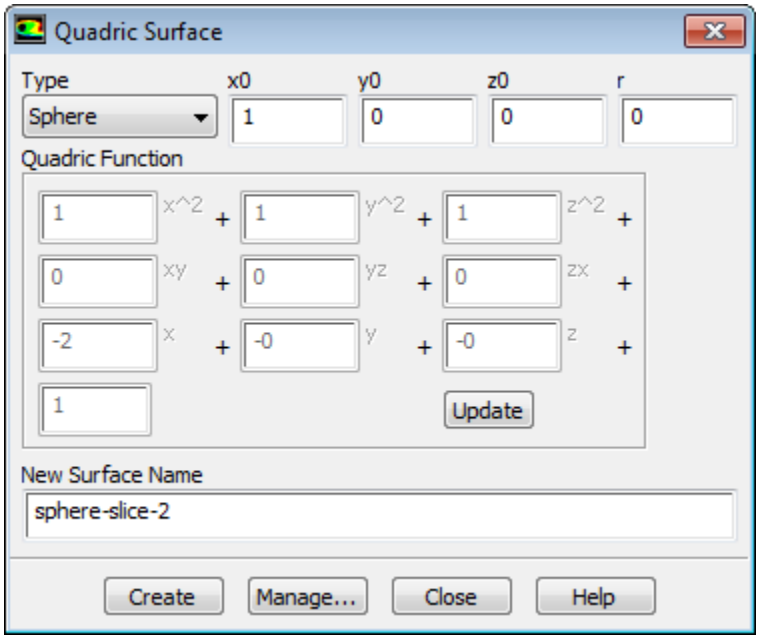
If you want to display data on a line (2D), plane (3D), circle (2D), sphere (3D), or general quadric surface, you can specify the surface by entering the coefficients of the quadric function that defines it. This feature provides you with an explicit method for defining surfaces. See Line and Rake Surfaces (p. 1718) and Plane Surfaces (p. 1722) for additional methods for creating line and plane surfaces.

To create a quadric surface, you will use the Quadric Surface Dialog Box (p. 2781) (Figure 30.12: The Quadric Surface Dialog Box (p. 1727)).

Setting Up Domain → Surface → Create → Quadric...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.12: The Quadric Surface Dialog Box



The steps for creating the quadric surface are as follows:

1. Decide which type of quadric surface you want to create. In 3D, choose **Plane**, **Sphere**, or (general) **Quadric** in the **Type** drop-down list. In 2D, choose **Line**, **Circle**, or **Quadric**.

2. Specify the defining equation for the surface *in SI units*.

   - Line or plane surface: If you have selected **Line** (in 2D) or **Plane** (in 3D) as the surface type, the surface will consist of all points on the domain that satisfy the equation $ix*x+iy*y+iz*z=\text{distance}$. You will specify **ix** (the coefficient of x), **iy** (the coefficient of y), **iz** (the coefficient of z), and **distance** (the distance of the line or plane from the origin) in the fields to the right of the **Type** drop-down list. When you click **Update** under the **Quadric Function** heading, the display of the quadric function coefficients will change to reflect your inputs.

   - Circle or sphere surface: If you have selected **Circle** (in 2D) or **Sphere** (in 3D) as the surface type, the surface will consist of all points on the domain that satisfy the equation $(x-x0)^2+(y-y0)^2+(z-z0)^2=r^2$. You will specify **x0**, **y0**, **z0** (the x, y, and z coordinates of the sphere or circle's center) and **r** (the radius) in the fields to the right of the **Type** drop-down list. When you click **Update** under the **Quadric Function** heading, the display of the quadric function coefficients will change to reflect your inputs.

   - Quadric surface: If you have selected **Quadric** as the surface type, the surface will consist of all points in the domain that satisfy the general quadric function $Q=\text{value}$. You will specify the coefficients of the quadric function Q (the coefficients of the terms x_2, y_2, z_2, xy, yz, zx, x, y, z and the constant term) directly in the **Quadric Function** box, and you will set **value** to the right of the **Type** drop-down list. Note that the **Update** button will be disabled when you choose this type of surface.

3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `sphere-slice-7` or `quadric-slice-10`). If the **New Surface Name** you enter is

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

4. Click **Create** to create the new surface.

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.8. Isosurfaces

If you want to display results on cells that have a constant value for a specified variable, you will need to create an isosurface of that variable. Generating an isosurface based on x, y, or z coordinate, for example, will give you an x, y, or z cross-section of your domain; generating an isosurface based on pressure will enable you to display data for another variable on a surface of constant pressure. You can create an isosurface from an existing surface or from the entire domain. Furthermore, you can restrict any isosurface to a specified cell zone.

Important

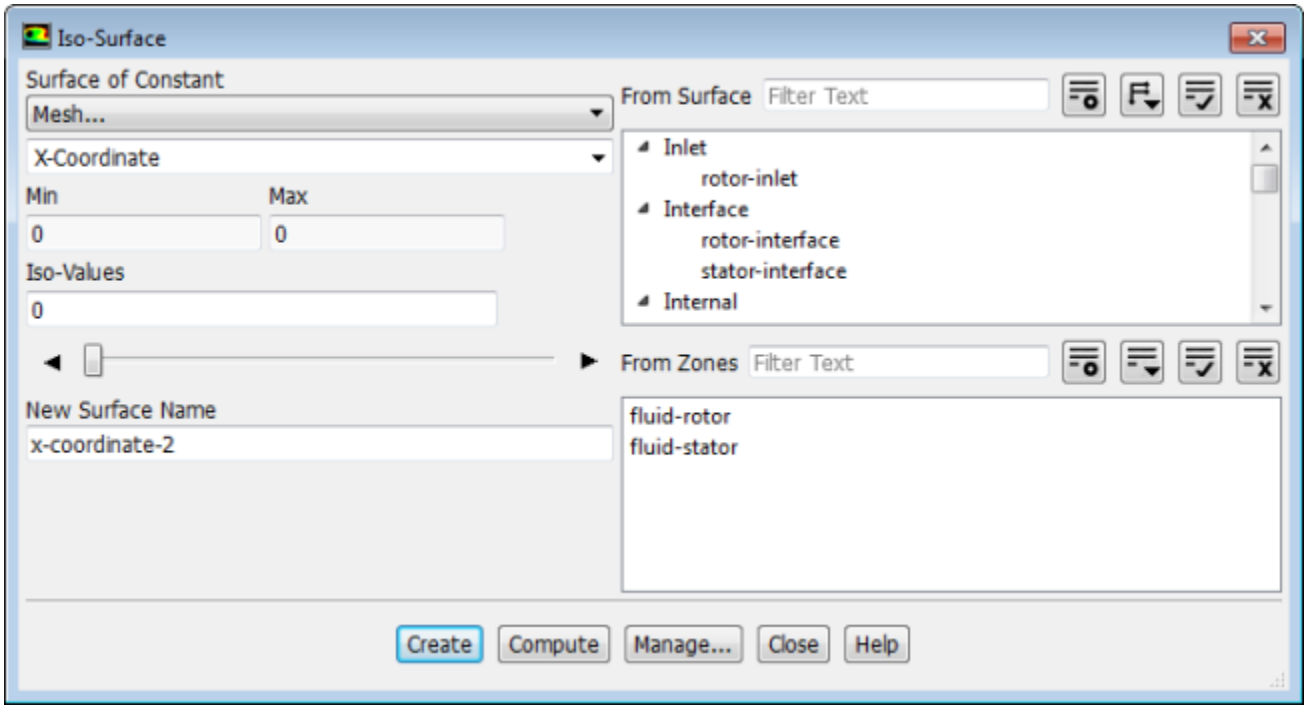
Note that you cannot create an isosurface until you have initialized the solution, performed calculations, or read a data file.

To create an isosurface, you will use the Iso-Surface Dialog Box (p. 2721) (Figure 30.13: The Iso-Surface Dialog Box (p. 1729)).

Setting Up Domain → Surface → Create → Iso-Surface...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.13: The Iso-Surface Dialog Box



The steps for creating the isosurface are as follows:

1. Choose the scalar variable to be used for isosurfacing in the **Surface of Constant** drop-down list. First, select the desired category in the upper list. You can then select from related quantities from the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

2. If you want to create an isosurface from an existing surface (that is, generate a new surface of constant x, y, temperature, pressure, and so on that is a subset of another surface), choose that surface in the **From Surface** list. You can specify the cell zone on which you want to create an isosurface by selecting the zone in the **From Zones** list.

   - If you do not select a surface from the list, the isosurfacing will be performed on the entire domain.
   - If you do not select a zone from the list, then the isosurfacing will not be restricted to any cell zone and will run through the entire domain.

3. Click **Compute** to calculate the minimum and maximum values of the selected scalar field in the domain or on the selected surface (in the **From Surface** list). The minimum and maximum values will be displayed in the **Min** and **Max** fields.

4. Set the isovalue using one of the following methods. (Note that the second method will enable you to define multiple isovalues in a single isosurface.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- You can set an isovalue interactively by moving the slider with the left mouse button. The value in the **Iso-Values** field will be updated automatically. This method will also create a temporary isosurface in the graphics window. Using the slider enables you to preview an isosurface before creating it.

  Important

  Even though the isosurface is displayed, it is only a temporary surface. To create an isosurface, use the **Create** button after deciding on a particular isovalue.

- You can type in isovalues in the **Iso-Values** field directly, separating multiple values by white space. Multiple isovalues will be contained in a single isosurface; that is, you cannot select subsurfaces within the resulting isosurface.

5. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `z-coordinate-6`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.)

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

6. Click **Create**. The new surface name will be added to the **From Surface** list in the dialog box.

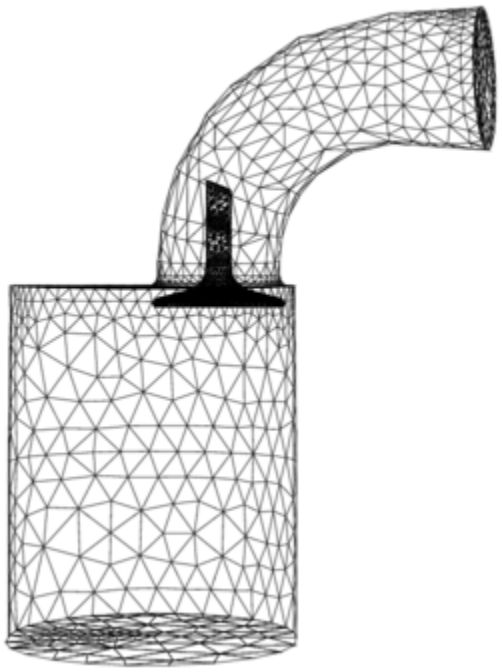
If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.9. Clipping Surfaces

If you have created a surface, but you do not want to use the whole surface to display data, you can clip the surface between two isovalues to create a new surface that spans a specified subrange of a specified scalar quantity. The clipped surface consists of those points on the selected surface where the scalar field values are within the specified range. For example, in Figure 30.14: External Wall Surface Isoclipped to Values of x Coordinate (p. 1731) the external wall has been clipped to values of x coordinate less than 0 to show only the back half of the wall, enabling you to see the valve inside the intake port.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

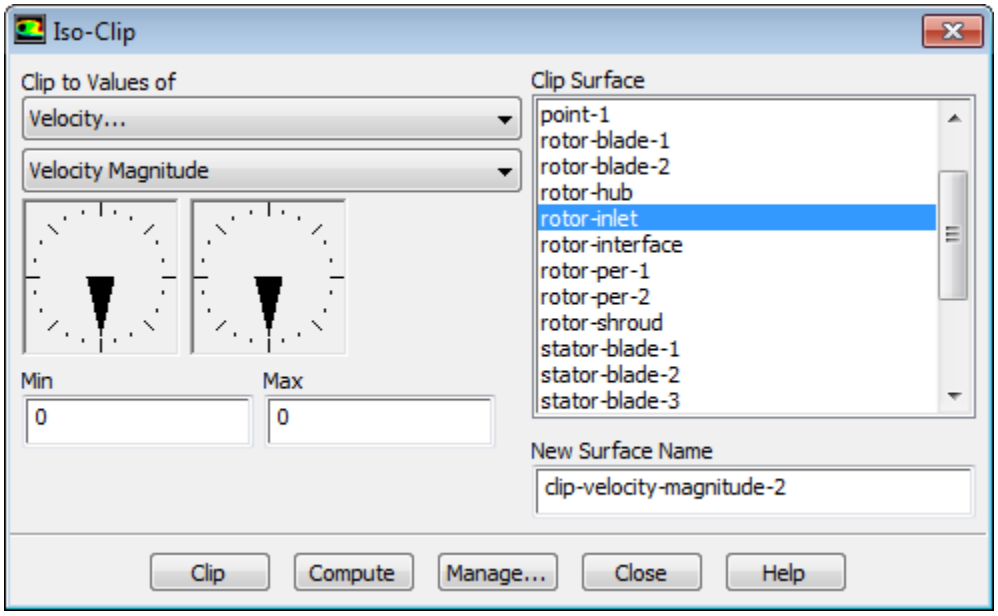
Figure 30.14: External Wall Surface Isoclipped to Values of x Coordinate



To clip an existing surface, you will use the Iso-Clip Dialog Box (p. 2720) (Figure 30.15: The Iso-Clip Dialog Box (p. 1731)).

Setting Up Domain → Surface → Create → Iso-Clip...

Figure 30.15: The Iso-Clip Dialog Box



The steps for clipping a surface are as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Choose the scalar variable on which the clipping will be based in the **Clip To Values Of** drop-down list. First, select the desired category in the upper list. You can then select from related quantities from the lower list. See Field Function Definitions (p. 1931) for an explanation of the variables in the list.

2. Select the surface to be clipped in the **Clip Surface** list.

3. Click **Compute** to calculate the minimum and maximum values of the selected scalar field on the selected surface. The minimum and maximum values are displayed in the **Min** and **Max** fields.

4. Define the clipping range using one of the following methods.

   - You can set the upper and lower limits of the clipping range interactively by moving the indicator in each dial (that is, the dial above the **Min** or **Max** field) with the left mouse button. The value in the corresponding **Min** or **Max** field is updated automatically. This method will also create a temporary surface in the graphics window. Using the dials enables you to preview a clipped surface before creating it.

     Important

     Even though the clipped surface is displayed, it is only a temporary surface. To create the new surface, use the **Clip** button after deciding on the clipping range.

   - You can type the minimum and maximum values in the clipping range directly in the **Min** and **Max** fields.

5. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `clip-density-8`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.)

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

6. Click **Clip**. The new surface name is added to the **Clip Surface** list in the dialog box. (The original surface will remain unchanged.)

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.10. Transforming Surfaces

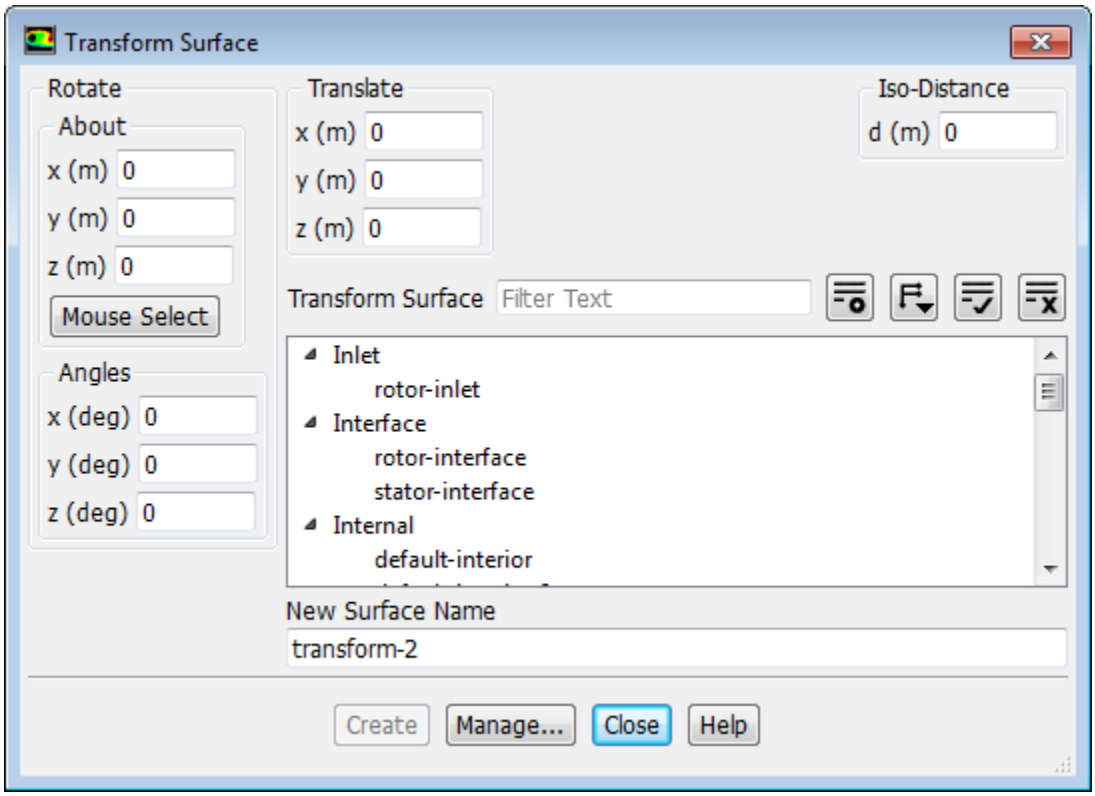
You can create a new data surface from an existing surface by rotating and/or translating the original surface. For example, you can rotate the surface of a complicated turbomachinery blade to plot data in the region between blades. You can also create a new surface at a constant normal distance from the original surface.

To transform an existing surface to create a new one, you will use the Transform Surface Dialog Box (p. 2812) (Figure 30.16: The Transform Surface Dialog Box (p. 1733)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Up Domain → Surface → Create → Transform...

Figure 30.16: The Transform Surface Dialog Box



The steps for transforming a surface are as follows:

1. Select the surface to be transformed in the **Transform Surface** list.

2. Set the appropriate transformation parameters, as described below. You can perform any combination of translation, rotation, and "isodistancing" on the surface.

   - Rotation: To rotate a surface, specify the origin about which the surface is rotated, and the angle by which the surface is rotated.

     In the **About** box under **Rotate**, specify a point, and the origin of the coordinate system for the rotation will be set to that point. (The x, y, and z directions will be the same as for the global coordinate system.) For example, if you specified the point (1,5,3) in 3D, rotation would be about the x, y, and z axes anchored at (1,5,3). You can either enter the point's coordinates in the **x**, **y**, and **z** fields or click **Mouse Select** and select a point in the graphics window using the mouse-probe button. See Controlling the Mouse Button Functions (p. 1800) for information about mouse button functions.

     In the **Angles** box under **Rotate**, specify the angles about the x, y, and z axes (that is, the axes of the coordinate system with the origin defined under **About**) by which the surface is rotated. For 2D problems, you can specify rotation about the z axis only.

   - Translation: To translate a surface, define the distance by which the surface is translated in each direction. Set the **x**, **y**, and **z** translation distances under **Translate**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Isodistancing: To create a surface positioned at a constant normal distance around the original surface, set the value for **d** under **Iso-Distance**.

3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `transform-9`). If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS Fluent will automatically assign the default name to the new surface when it is created.

   Important

   The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

4. Click **Create**. The new surface name is added to the **Transform Surface** list in the dialog box. The original surface will remain unchanged.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the Surfaces Dialog Box (p. 2810). See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details.

30.1.11. Grouping, Renaming, and Deleting Surfaces

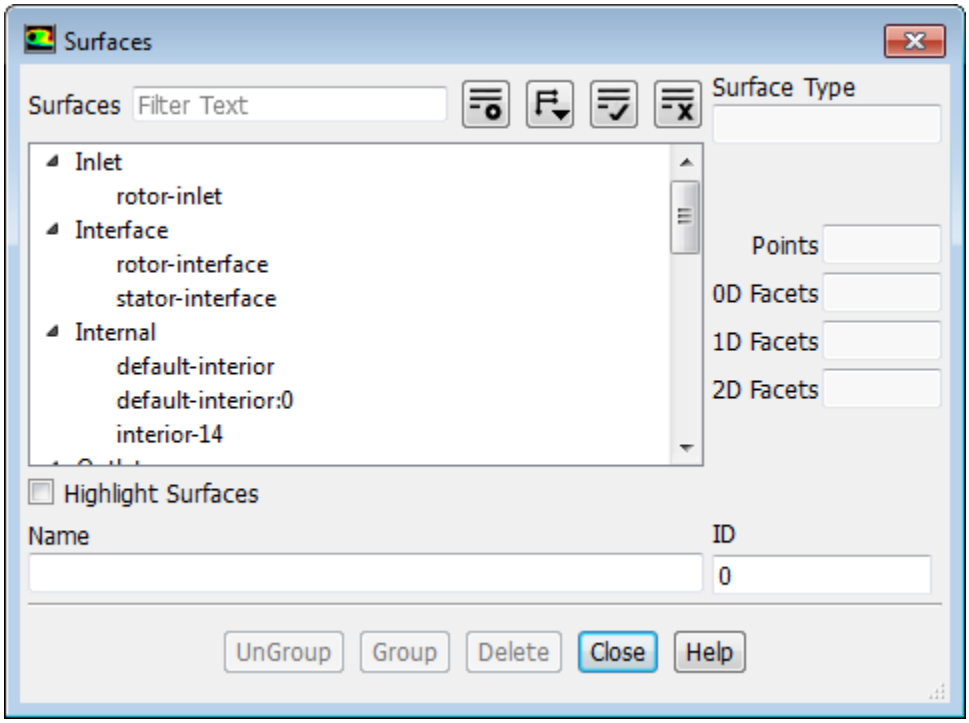
Once you have created a number of surfaces, you can interactively rename, delete, and group surfaces and obtain information about their components. Grouping surfaces is useful if you want to perform postprocessing on a number of surfaces at a time. For example, you may want to group several wall surfaces together to generate a contour plot of temperature on all walls. To postprocess results on each wall surface individually, "ungroup" the surfaces.

Manipulation of existing surfaces is performed with the Surfaces Dialog Box (p. 2810) (Figure 30.17: The Surfaces Dialog Box (p. 1735)).

Setting Up Domain → Surface → Manage...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.17: The Surfaces Dialog Box



You can also open this dialog box by clicking **Manage...** in one of the surface creation dialog boxes described in the previous sections.

For additional information, see the following sections:
30.1.11.1. Grouping Surfaces
30.1.11.2. Renaming Surfaces
30.1.11.3. Deleting Surfaces
30.1.11.4. Surface Statistics

30.1.11.1. Grouping Surfaces

As mentioned above, you may want to group several surfaces together in order to perform postprocessing on all of them at once. To create a surface group, select the surfaces to be grouped in the **Surfaces** list. You can define a new name for the group in the **Name** field, or you can use the default name, which is the name of the first surface you selected in the **Surfaces** list. Then click **Group**. The selected surfaces disappear from the **Surfaces** list, and the name of the surface group is added to the list.

Important

The **Group** button will not appear until you have selected at least two surfaces. As soon as you choose a second surface in the **Surfaces** list, the **Rename** button will change to the **Group** button.

To ungroup the surfaces, simply select the surface group in the **Surfaces** list and click **UnGroup**. The group name will disappear from the list and the names of the original surfaces in the group will reappear in the list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

30.1.11.2. Renaming Surfaces

To change the name of an existing surface, select the surface in the **Surfaces** list, enter a new name in the **Name** field, and then click **Rename**. The new name replaces the old name in the **Surfaces** list and the surface is otherwise unchanged.

If you have selected more than one surface, the **Rename** button will not appear in the dialog box. When more than one surface is selected, the **Rename** button is replaced by the **Group** button.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS Fluent rejects the entry.

30.1.11.3. Deleting Surfaces

If you find that a surface is no longer useful, you may want to delete it to prevent the list of surfaces from becoming too cluttered. Select the surface or surfaces to be deleted in the **Surfaces** list, and then click **Delete**. The delete operation is not reversible, so if you want to get a deleted surface back again you will need to recreate it using one of the surface-creation dialog boxes described in the previous sections.

30.1.11.4. Surface Statistics

You can also use the Surfaces Dialog Box (p. 2810) to retrieve topological information about surfaces. **Points** is the total number of nodes in a surface. **0D Facets** is the number of isolated nodes in a surface (that is, nodes that have no connectivity, such as point surfaces or nodes in a rake), **1D Facets** is the number of linear faces (consisting of two connected nodes) in a surface in a 2D problem, and **2D Facets** is the number of 2D faces (triangular or quadrilateral) in a surface in a 3D problem. Note that an **interior** zone surface in a 3D problem consists of 2D facets, and similarly an **interior** zone surface in a 2D problem consists of 1D facets.

These statistics are listed for the surface(s) selected in the **Surfaces** list. If more than one surface is selected, the sum over all selected surfaces is displayed for each quantity.

Note that if you want to check these statistics for a surface that was read from a case file, you will need to first display it.

30.2. Using Cell Registers

The following sections describe how to create and use cell registers:

30.2.1. Region
30.2.2. Boundary
30.2.3. Variable Limiter
30.2.4. Field Variable
30.2.5. Residuals
30.2.6. Volume
30.2.7. Yplus/Ystar
30.2.8. Manage Cell Registers
30.2.9. Cell Register Operations

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

30.2.1. Region

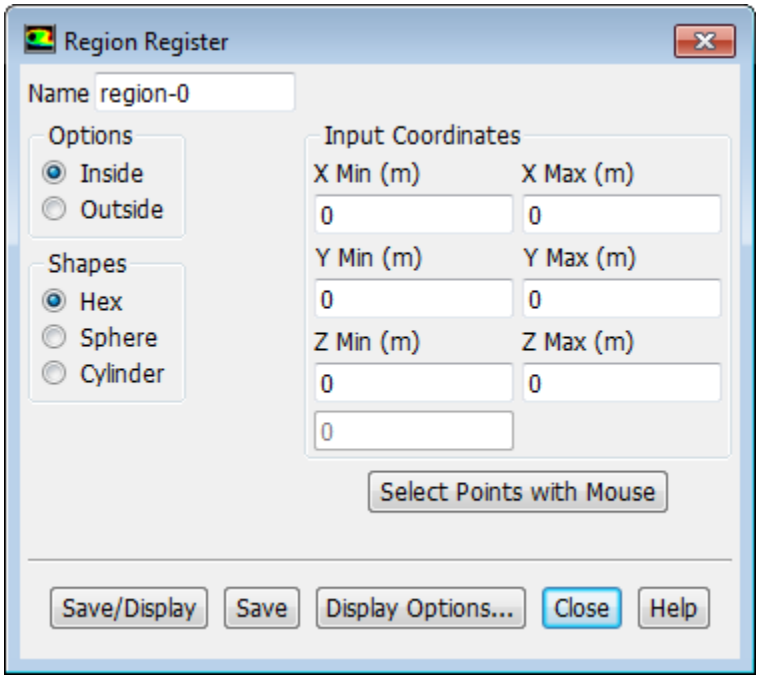
Region registers allow you to mark cells inside or outside of a given region that you can specify using text or mouse inputs. Using text input, you can specify the region as a hexahedron (quadrilateral in 2D), a sphere (circle in 2D), or a cylinder. For additional information on region cell registers, see Region Adaption in the *Fluent Theory Guide*.

To create a region cell register:

1. Open the Figure 30.18: Region Register Dialog Box (p. 1737).

   Solution → **Cell Registers** **New** → **Region...**

   Figure 30.18: Region Register Dialog Box



2. Specify whether the register includes cells **Inside** or **Outside** of the defined region.

3. Choose the shape for the region register.

4. Specify the coordinates of the region.

   You can either enter the X, Y, and Z values manually to create the region, or you can click **Select Points with Mouse** to use the mouse-probe to select the points directly on the model in the graphics window.

5. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Register Display Options dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.2. Boundary

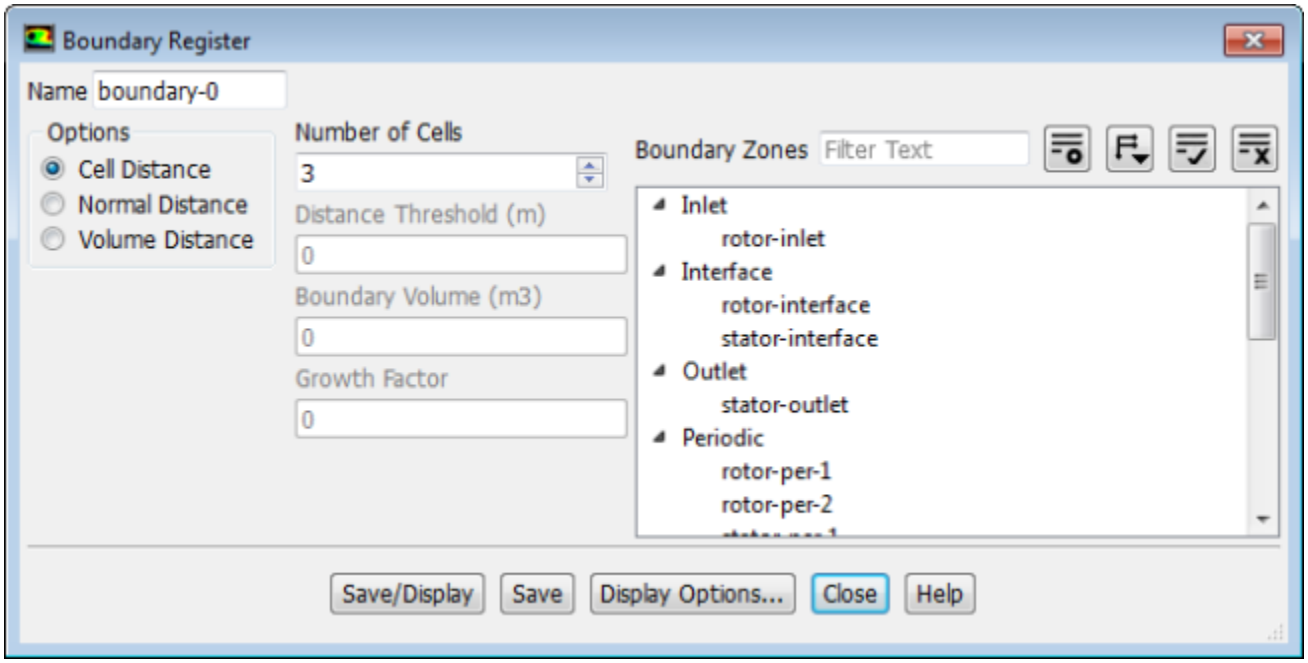
Boundary registers allow you to mark cells within the proximity of a boundary. The proximity to the boundary can be based on cell distance, normal distance, or volume distance. For additional information on boundary registers, see Boundary Adaption in the *Fluent Theory Guide*.

To create a boundary cell register:

1. Open the Figure 30.19: Boundary Register Dialog Box (p. 1738).

   Solution → **Cell Registers** **New** → **Boundary...**

   Figure 30.19: Boundary Register Dialog Box



2. Choose whether the boundary register is based on **Cell Distance**, **Normal Distance**, or **Volume Distance**.
3. Specify the **Number of Cells**, **Distance Threshold**, or **Boundary Volume** and **Growth Factor**, depending on which distance method you selected in the previous step.
4. Select the boundary zone(s) for the cell register.
5. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Register Display Options dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.3. Variable Limiter

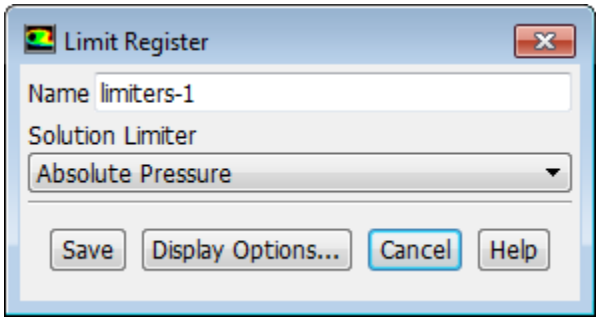
Limit registers allow you to mark the cells that have reached a solution limit while solving. These limits can be viewed and modified in Figure 28.11: The Solution Limits Dialog Box (p. 1586). For additional information on solution limits, see Setting Solution Limits (p. 1586).

To create a limit cell register:

1. Open the Figure 30.20: Limit Register Dialog Box (p. 1739).

   Solution → Cell Registers **New → Variable Limiter...**

   Figure 30.20: Limit Register Dialog Box

2. Select the variable for creating the cell register.
3. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell Register Display Options** dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.4. Field Variable

Field variable registers allow you to mark cells based on the value of a field variable. You can mark cells based on the minimum/maximum value of a field variable, inside or outside of a certain range of field variable values, or within a certain percentage of the minimum/maximum value of a field variable.

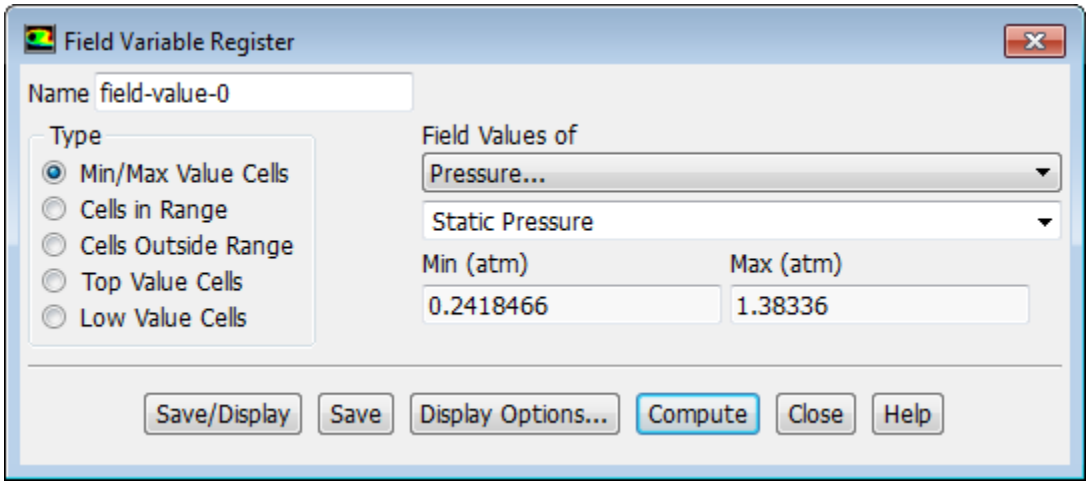
To create a field variable cell register:

1. Open the Figure 30.21: Field Variable Register Dialog Box (p. 1740).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → Cell Registers → New → Field Variable...

Figure 30.21: Field Variable Register Dialog Box



2. Choose the **Type** of field variable register. Note that you can use **Compute** to calculate the minimum and maximum values of the chosen field variable.
3. Select the field variable for creating the cell register from the **Field Values of** drop-down lists.
4. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell Register Display Options** dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.5. Residuals

Residual registers allow you to mark cells based on their residuals values. You can visualize the cells with the highest residual values and know their location so that you can modify them as necessary.

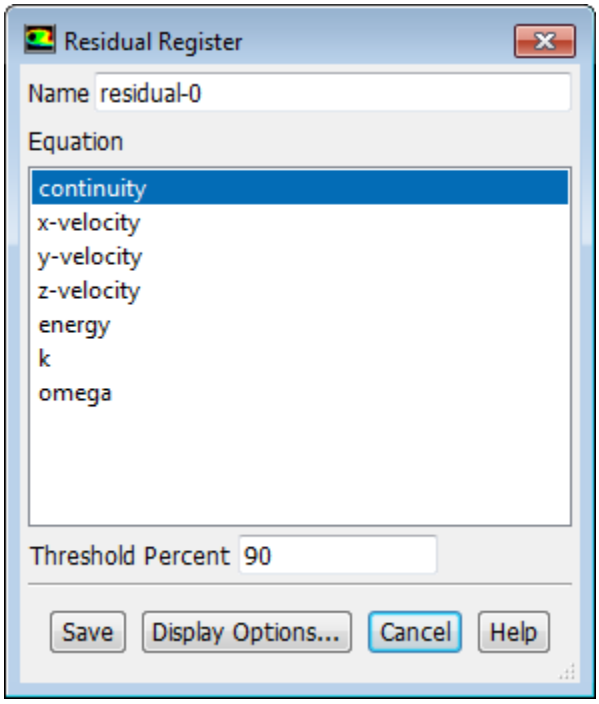
To create a residual cell register:

1. Open the Figure 30.22: Residual Register Dialog Box (p. 1741).

Solution → Cell Registers → New → Residuals...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.22: Residual Register Dialog Box



2. Select the **Equation**(s) for creating the residual cell register.

3. Specify the **Threshold Percent** for creating the residual cell register. Cells with residual values above this threshold for the selected equations are marked.

4. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell Register Display Options** dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.6. Volume

Volume registers allow you to mark cells based on the volume of the cells, either the magnitude or the change in volume. For additional information on volume cell registers, see Volume Adaption in the *Fluent Theory Guide*.

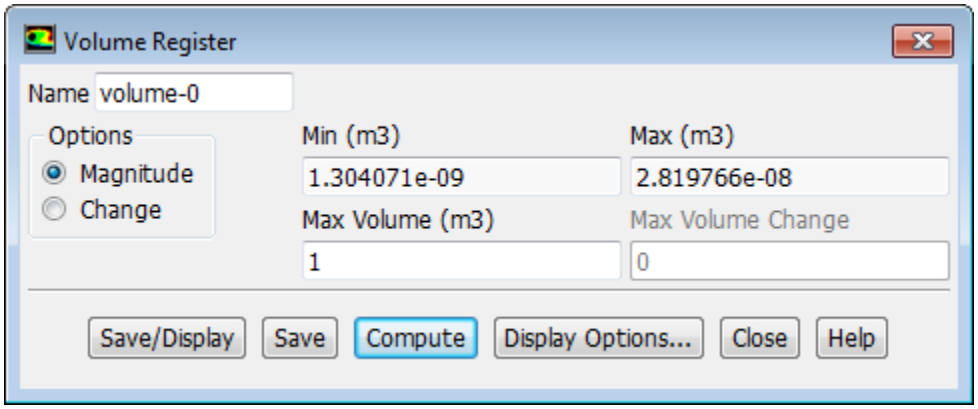
To create a volume cell register:

1. Open the Figure 30.23: Volume Register Dialog Box (p. 1742).

Solution → Cell Registers → New → Volume...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.23: Volume Register Dialog Box



2. Choose whether the cell register is based on the maximum size of the cells (**Magnitude**) or the **Change** in volume of the cells.

3. Specify the **Max Volume** or **Max Volume Change**. Note that you can click **Compute** to compute the minimum and maximum cell volumes.

4. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell Register Display Options** dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.7. Yplus/Ystar

Yplus/Ystar registers allow you to mark cells based on their Yplus/Ystar values. For additional information on Yplus/Ystar cell registers, see Yplus/Ystar Adaption in the *Fluent Theory Guide*.

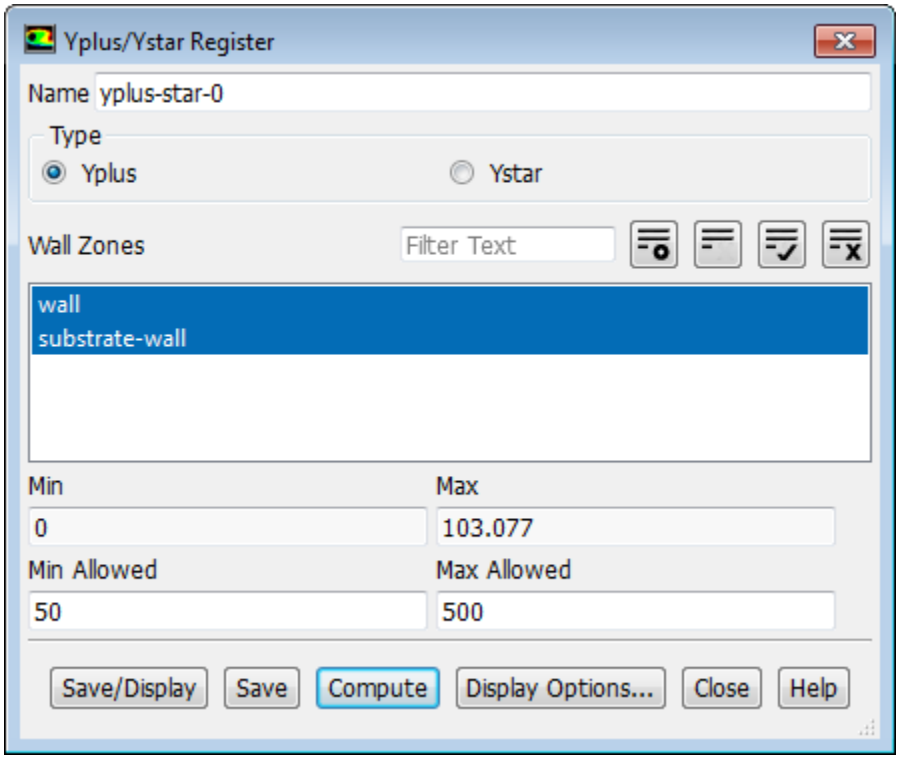
To create a Yplus/Ystar cell register:

1. Open the Figure 30.24: Yplus/Ystar Register Dialog Box (p. 1743).

   Solution → **Cell Registers** → **New** → **Yplus/Ystar...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.24: Yplus/Ystar Register Dialog Box



2. Choose whether the cell register is based on **Yplus** or **Ystar** values.
3. Select the **Wall Zones** for the Yplus or Ystar calculations.
4. Specify the minimum and maximum Yplus/Ystar values allowed. Note that clicking **Compute** calculates the minimum and maximum Yplus/Ystar values.
5. Click **Save** to create the cell register.

Note

You can change the way the register is displayed by using the **Cell Register Display Options** dialog box that opens by clicking **Display Options...**. The controls in the **Cell Register Display Options** dialog box are similar to those in the Adaption Display Options Dialog Box (p. 2663).

30.2.8. Manage Cell Registers

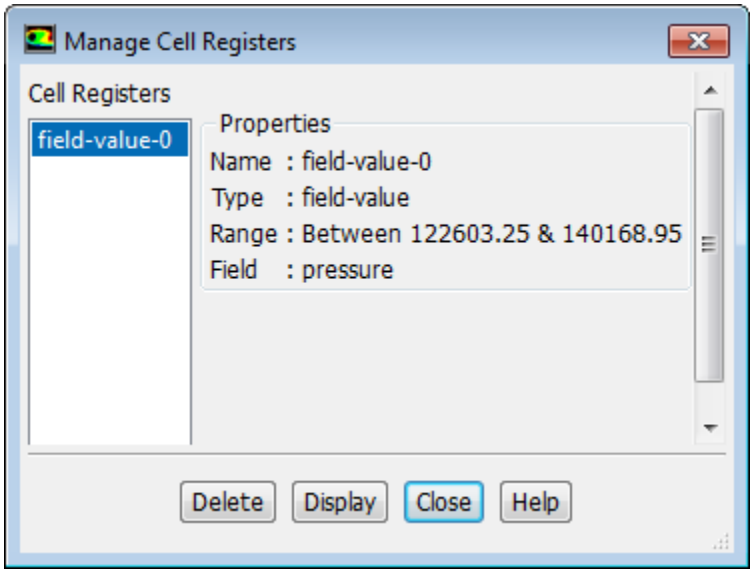
The Figure 30.25: Manage Cell Registers Dialog Box (p. 1744) allows you to review the properties of the currently defined cell registers. You can also use it to display and delete the selected cell register.

To manage cell registers:

1. Open the Figure 30.25: Manage Cell Registers Dialog Box (p. 1744).

   Solution → **Cell Registers** **Edit...**

Figure 30.25: Manage Cell Registers Dialog Box



2. Select a cell register to: view its properties, display it, or delete it.

30.2.9. Cell Register Operations

Once a cell register is defined, you can create a cell register operation to report the residual values of the selected cell registers at the interval you specify.

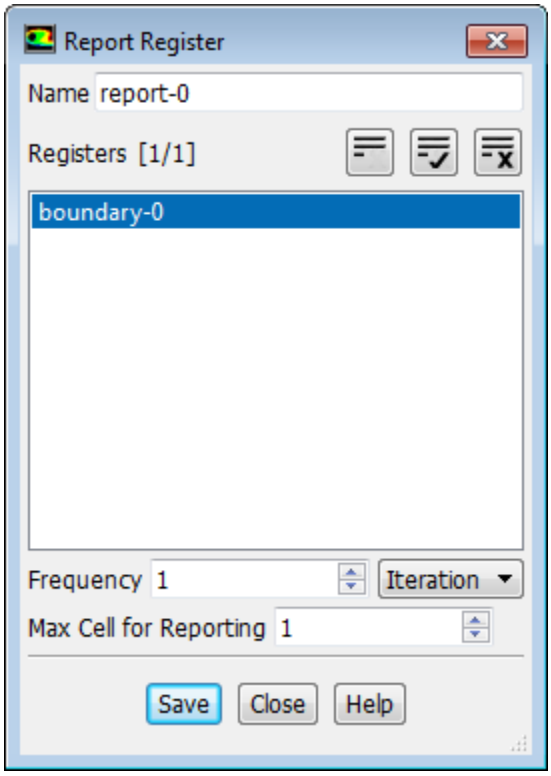
To create a register report:

1. Open the Figure 30.26: Report Register Dialog Box (p. 1745).

Solution → Calculation Activities → Cell Register Operations → New Report...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 30.26: Report Register Dialog Box



Note that this dialog box is only available after you have defined a cell register.

2. Select the cell register(s) you want included in the report.
3. Specify the reporting **Frequency**.
4. Specify the maximum number of cells to include in the report.
5. Click **Save** to create the cell register report.

The Figure 30.27: Manage Register Operations Dialog Box (p. 1746) allows you to view properties, create, modify, and delete report registers.

Solution → Calculation Activities → Cell Register Operations Edit...

Figure 30.27: Manage Register Operations Dialog Box

Chapter 31: Displaying Graphics

Graphics tools available in ANSYS Fluent enable you to process the information contained in your CFD solution and easily view the results. The following sections explain how to use these tools to examine your solution. The procedure for saving picture files of graphics displays is described in Saving Picture Files (p. 102).

31.1. Basic Graphics Generation
31.2. Customizing the Graphics Display
31.3. Controlling the Mouse Button Functions
31.4. Viewing the Application Window
31.5. Modifying the View
31.6. Advanced Scene Composition
31.7. Animating Graphics
31.8. Creating Videos
31.9. Histogram and XY Plots
31.10. Turbomachinery Postprocessing
31.11. Fast Fourier Transform (FFT) Postprocessing

31.1. Basic Graphics Generation

In ANSYS Fluent, you can generate graphics displays showing meshes, contours, profiles, vectors, pathlines, and scenes. Some graphics are generated using variables that are plotted directly from the ANSYS Fluent data file once the file has been read. The variables listed in the data file depend on the models active at the time the file is written. Variables that are required by the solver, based on the current model settings, but are missing from the data file are set to their default values. For those missing variables, one iteration should be performed in order to obtain the required values for generating the plot. A complete list of variables stored in the data file is available in (`xfile.h`) and can be accessed as stated in Data Sections (p. 2865). The following sections describe how to create these plots. (Generation of histogram and XY plots is discussed in Histogram and XY Plots (p. 1838).)

Important

If your model includes a discrete phase, you can also display the particle trajectories, as described in Displaying of Trajectories (p. 1330).

Note

There are two kinds of graphics objects—those whose settings are saved with the case file for reuse during the simulation, and those that are not. Persistent graphics objects (saved with the case file) are accessed by clicking **New...**, non-persistent objects are created by clicking **Edit...**. For example, you can create a persistent contour plot by clicking **Contours** and selecting **New...** in the **Postprocessing** ribbon tab (**Graphics** group box).

Postprocessing → **Graphics** → **Contours** → **New...**

This section discusses the following topics:

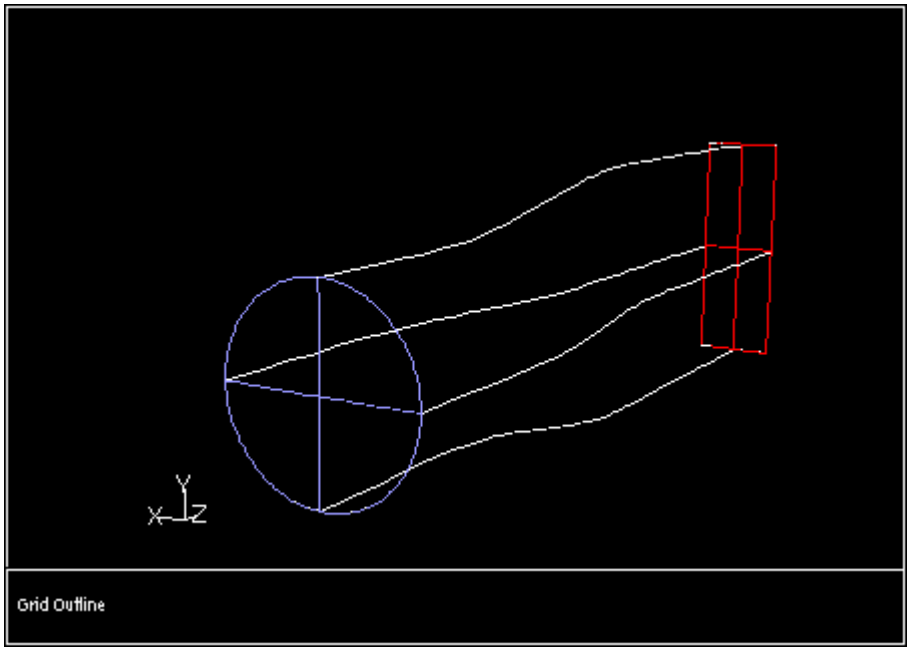
31.1.1. Displaying the Mesh
31.1.2. Displaying Contours and Profiles
31.1.3. Displaying Vectors
31.1.4. Displaying Pathlines
31.1.5. Displaying a Scene
31.1.6. Displaying Results on a Sweep Surface
31.1.7. Hiding the Graphics Window Display

31.1.1. Displaying the Mesh

During the problem setup or when you are examining your solution, you may want to look at the mesh associated with certain surfaces. You can do the following:

- Display the outline of all or part of the domain, as shown in Figure 31.1: Outline Display (p. 1748).

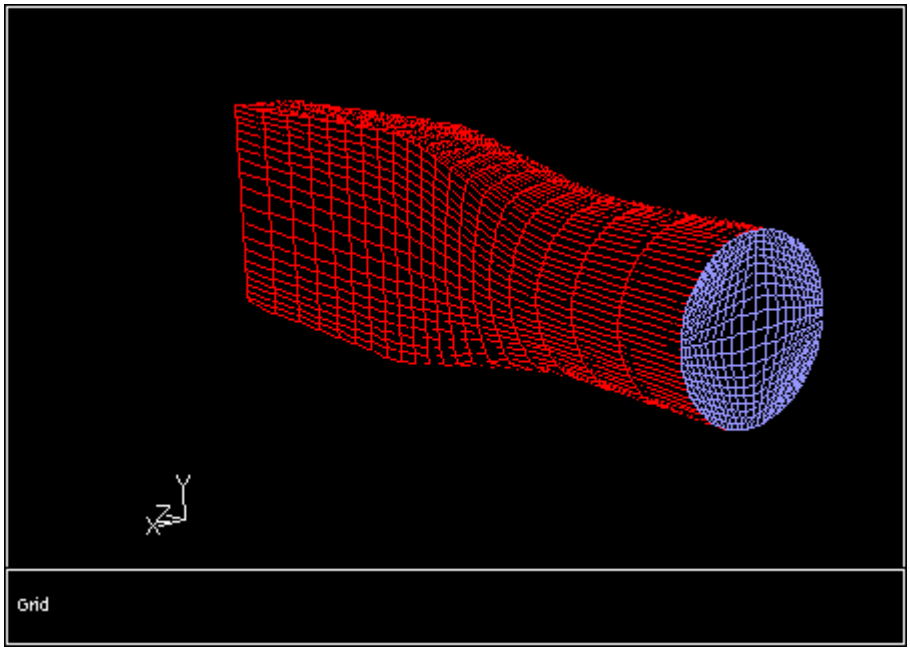
Figure 31.1: Outline Display



- Draw the mesh lines (edges), as shown in Figure 31.2: Mesh Edge Display (p. 1749).

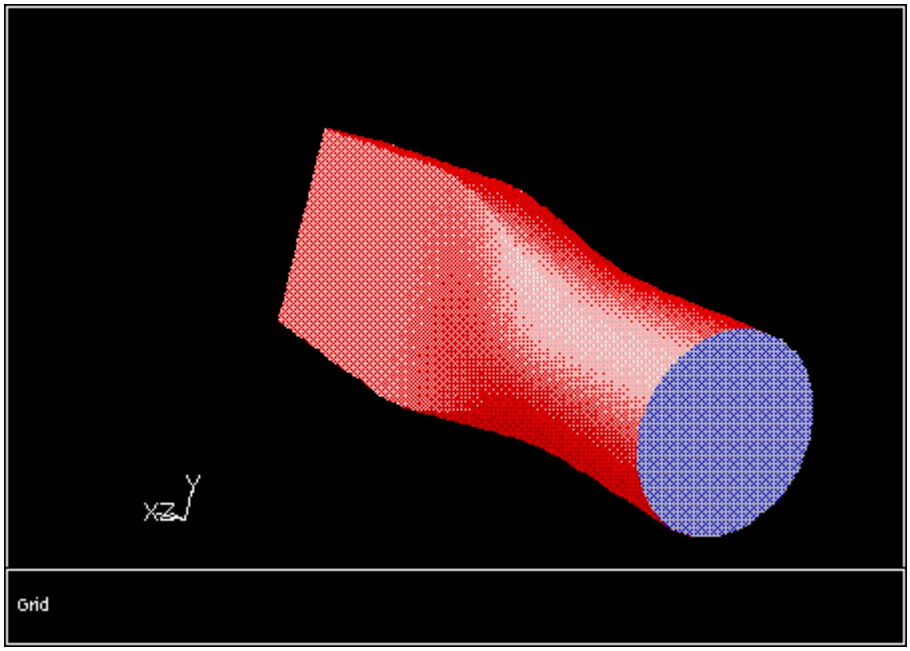
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.2: Mesh Edge Display



- Draw the solid surfaces (filled meshes) for a 3D domain, as shown in Figure 31.3: Mesh Face (Filled Mesh) Display (p. 1749).

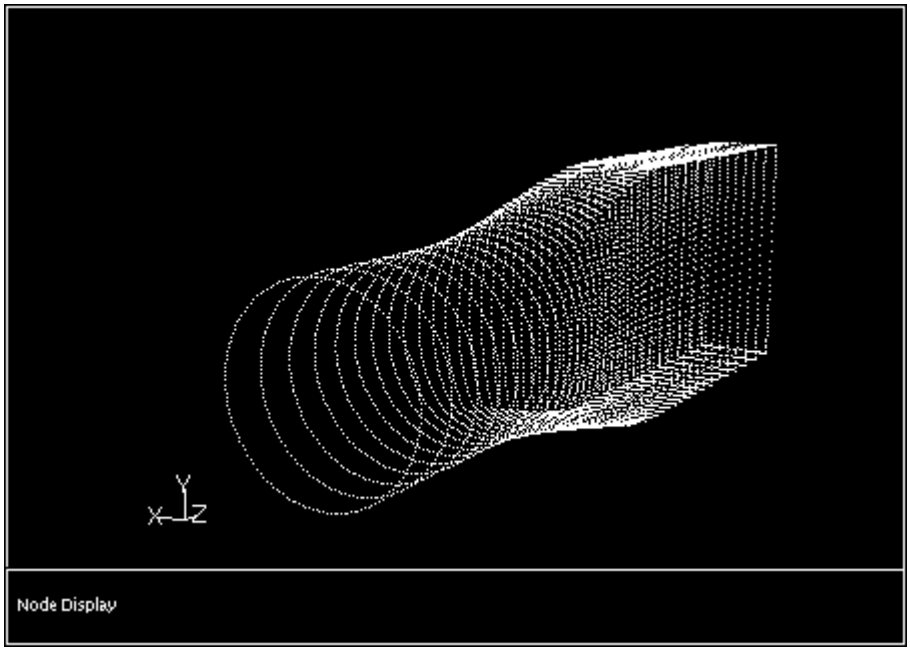
Figure 31.3: Mesh Face (Filled Mesh) Display



- Draw the nodes on the domain surfaces, as shown in Figure 31.4: Node Display (p. 1750).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.4: Node Display



Note

The **Post Processing** option for mesh display configuration is recommended when postprocessing your results in ANSYS Fluent. This option is accessed by clicking in the objects toolbar or by entering `dislay/set/mesh-display-configuration` in the console.

For information about displaying the mesh on a surface that sweeps through the domain, see Displaying Results on a Sweep Surface (p. 1782).

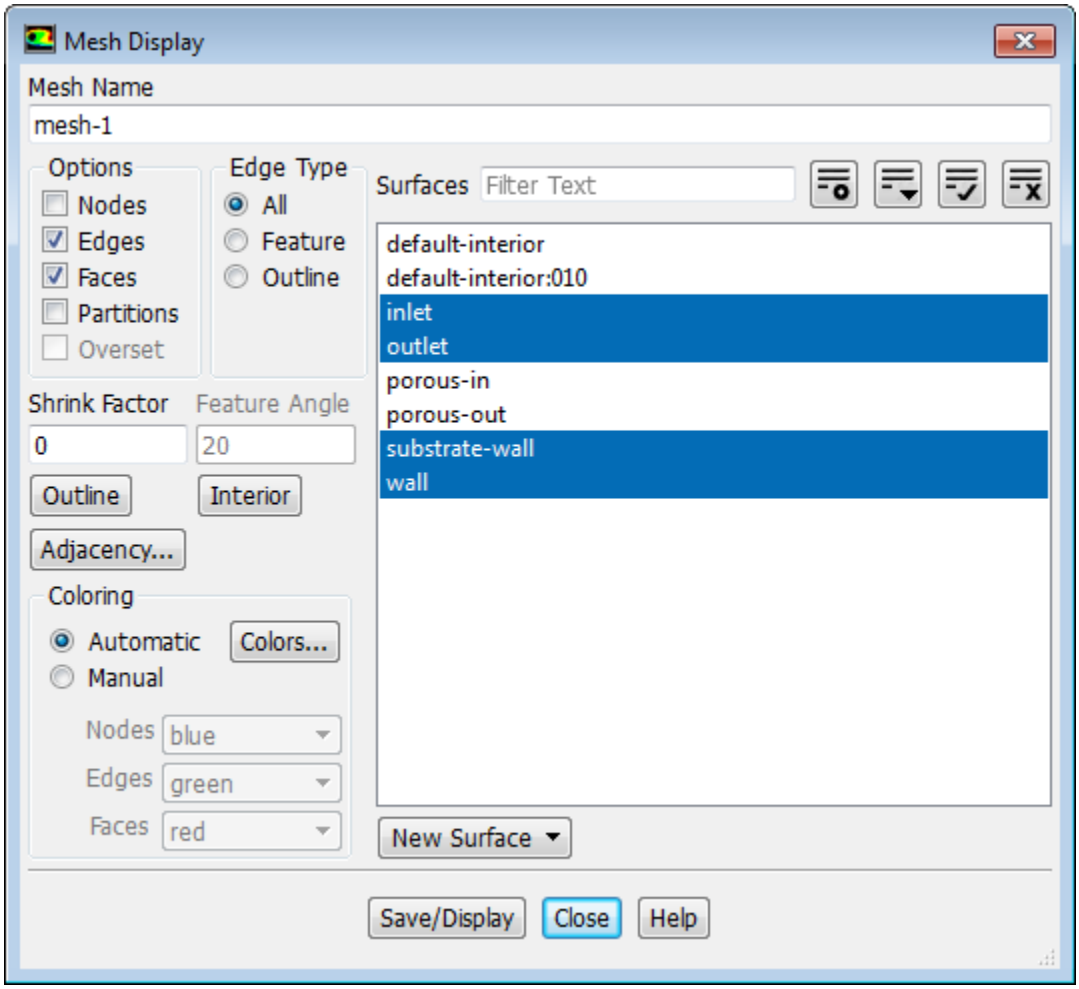
31.1.1.1. Generating Mesh or Outline Plots

You can draw the mesh or outline for all or part of your domain using the Mesh Display Dialog Box (p. 2163) (Figure 31.5: The Mesh Display Dialog Box (p. 1751)).

Results → Graphics → Mesh Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.5: The Mesh Display Dialog Box



The basic steps for generating a mesh or outline plot are as follows:

1. Choose the surfaces for which you want to display the mesh or outline in the **Surfaces** list.

   If you want to select several surfaces of the same type, click and select **Surface Type** under **Group By**, which organizes the surfaces in a tree view that is grouped by surface type.

   Another shortcut is to use the **Filter Text** entry box to filter the **Surfaces** list to show only the surfaces that match the pattern you enter. For additional information on using the **Filter Text** entry box, see Filter Text Entry Boxes (p. 15).

2. Depending on what you want to draw, do one or more of the following:

   - To draw an outline of the selected surfaces (as in Figure 31.1: Outline Display (p. 1748)), select **Edges** under **Options** and **Outline** under **Edge Type**. If you need more detail in the outline display of a complex geometry, see the description of the **Feature** option, below.

   - To draw the mesh edges (as in Figure 31.2: Mesh Edge Display (p. 1749)), select **Edges** under **Options** and **All** under **Edge Type**.

   - To generate a filled-mesh display (as in Figure 31.3: Mesh Face (Filled Mesh) Display (p. 1749)), select **Faces** under **Options**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To draw the nodes on the selected surfaces (as in Figure 31.4: Node Display (p. 1750)), select **Nodes** under **Options**.

3. Set any of the mesh and outline display options described in the following section.

4. Click **Display** to draw the specified mesh or outline in the active graphics window.

To display filled meshes, with smoothly shaded display, enable lighting and select a lighting interpolation method other than **Flat** in the Display Options Dialog Box (p. 2573) or the Lights Dialog Box (p. 2588).

If you display nodes, and you want to change the symbol representing the nodes, you can change the **Point Symbol** in the Display Options Dialog Box (p. 2573). See Modifying the Rendering Options (p. 1798) for details.

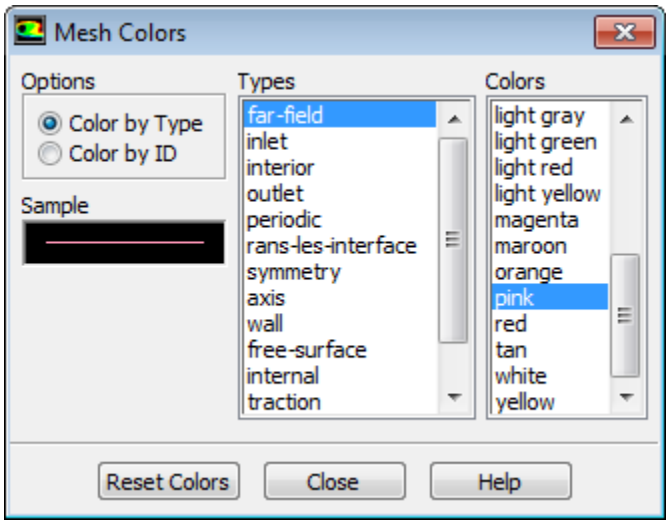
31.1.1.2. Mesh and Outline Display Options

The options mentioned in the procedure in the previous section include modifying the mesh colors, adding the outline of important features to an outline display, drawing partition boundaries, and shrinking the faces and/or cells in the display.

31.1.1.2.1. Modifying the Mesh Colors

ANSYS Fluent enables you to control the colors that are used to render the meshes for each zone type or surface. This capability can help you to understand mesh plots quickly and easily. To modify the colors, open the Mesh Colors Dialog Box (p. 2168) (Figure 31.6: The Mesh Colors Dialog Box (p. 1752)) by clicking **Colors...** in the Mesh Display Dialog Box (p. 2163).

Figure 31.6: The Mesh Colors Dialog Box



You can set colors individually for the meshes displayed on each surface, using the Scene Description Dialog Box (p. 2577).

By default, the **Color by Type** option is turned on, enabling you to assign colors based on zone type. To change the color used to draw the mesh for a particular zone type, select the zone type in the **Types** list and then select the new color in the **Colors** list. You will see the effect of your change when you next display the mesh. Note that the **surface** type in the **Types** list applies to all surface meshes (that

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

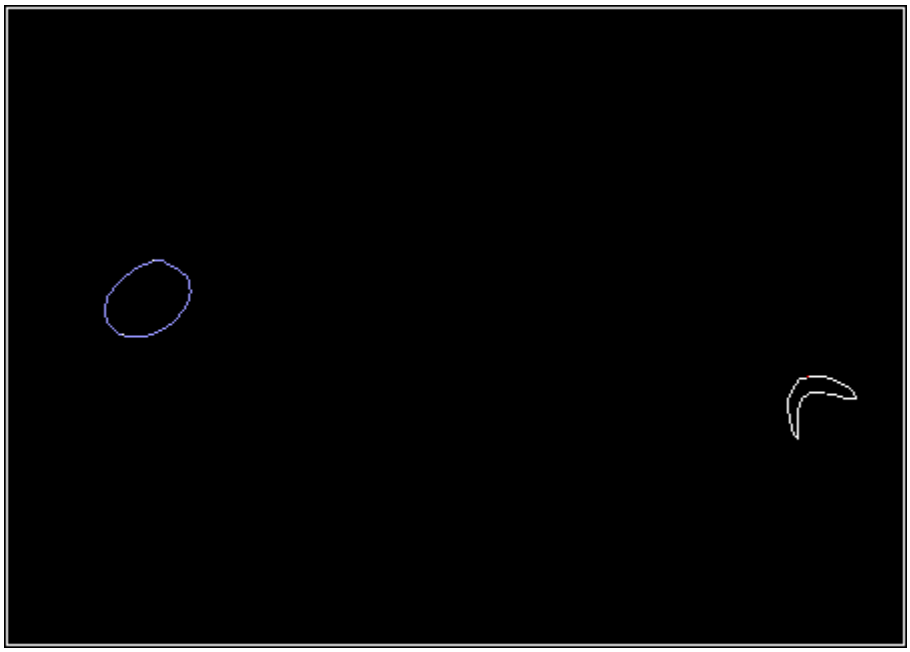
is, meshes that are drawn for surfaces created using the dialog boxes opened from the **Create** button in the **Surface** group box of the **Setting Up Domain** ribbon tab) except zone surfaces.

If you prefer to use the colors ANSYS Fluent assigns by zone ID, then you can display the mesh using the **Color by ID** option.

31.1.1.2.2. Adding Features to an Outline Display

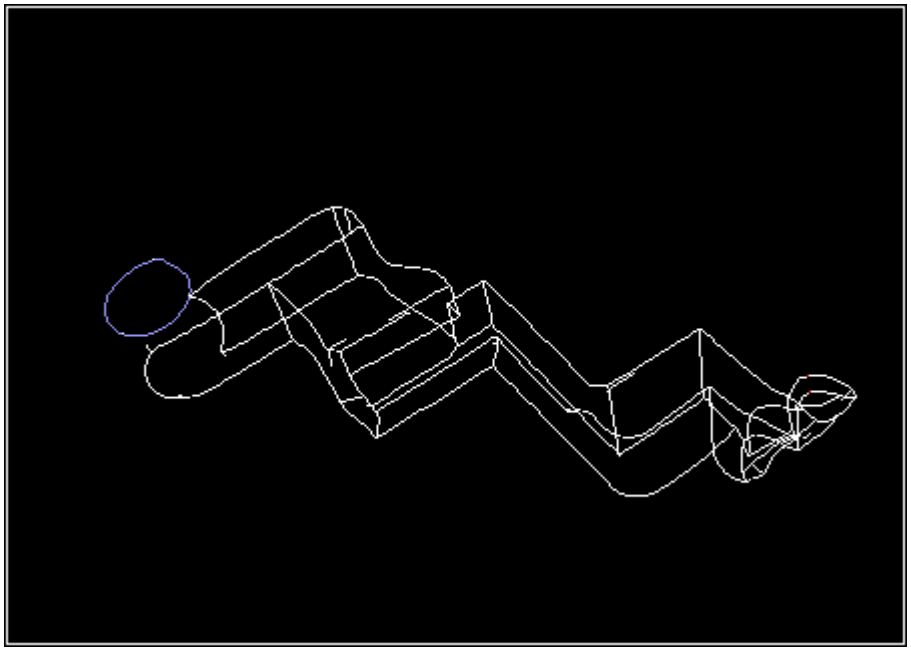
For closed 3D geometries such as cylinders, the standard outline display often will not show enough detail to accurately depict the shape. This is because for each boundary, only those edges on the "outside" of the geometry (that is, those that are used by only one face on the boundary) are drawn. In Figure 31.7: Standard Outline of Complex Duct (p. 1753), which shows the outline display for a complicated duct geometry, only the inlet and outlet are visible.

Figure 31.7: Standard Outline of Complex Duct



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.8: Feature Outline of Complex Duct



You can capture additional features using the **Feature** option in the Mesh Display Dialog Box (p. 2163). (See Figure 31.8: Feature Outline of Complex Duct (p. 1754).) Enable **Feature** under **Edge Type**, and then set the **Feature Angle**. With the default **Feature Angle** of 20, if the difference between the normal directions of two adjacent faces is more than 20°, the edge between those faces will be drawn. Decreasing the **Feature Angle** will result in more edge lines (that is, more detail) being added to the outline display. The appropriate angle for your geometry will depend on its curvature and complexity. You can modify the **Feature Angle** until you find the value that yields the best outline display.

31.1.1.2.3. Drawing Partition Boundaries

If you have partitioned your mesh for parallel processing, you can add the display of partition boundaries to the mesh display by turning on the **Partitions** option in the Mesh Display Dialog Box (p. 2163).

31.1.1.2.4. Shrinking Faces and Cells in the Display

To distinguish individual faces or cells in the display, enlarge the space between adjacent faces or cells by increasing the **Shrink Factor** in the Mesh Display Dialog Box (p. 2163). The default value of zero produces a display in which the edges of adjacent faces or cells overlap. A value of 1 creates the opposite extreme: each face or cell is represented by a point and there is considerable space between each one. A small value such as 0.01 may be large enough to enable you to distinguish one face or cell from its neighbor. Displays with different **Shrink Factor** values are shown in Figure 31.9: Mesh Display with Shrink Factor = 0 (p. 1755) and Figure 31.10: Mesh Display with Shrink Factor = 0.01 (p. 1755). Click **Display** to see the effect of the change in **Shrink Factor**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.9: Mesh Display with Shrink Factor = 0

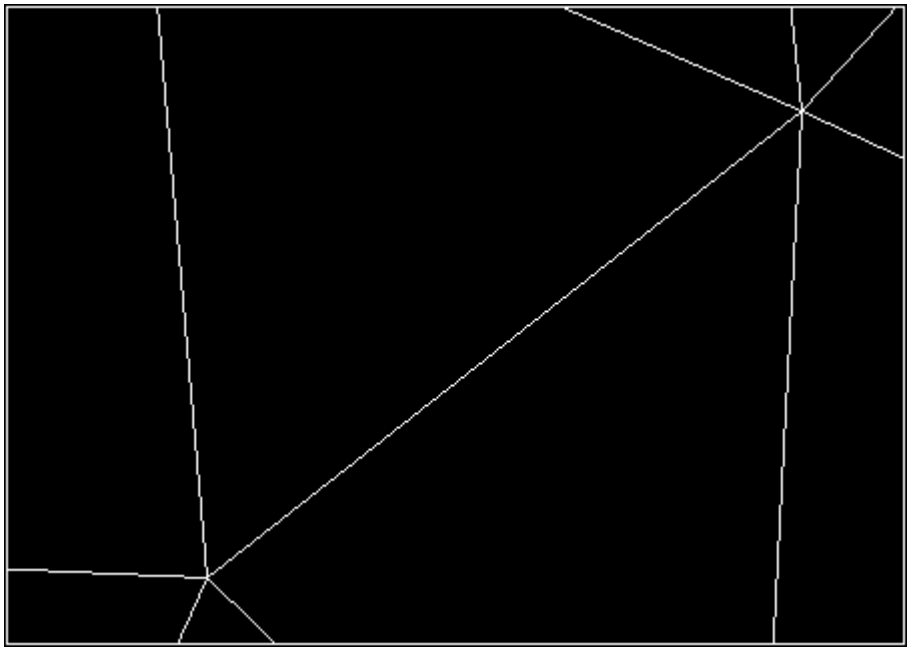


Figure 31.10: Mesh Display with Shrink Factor = 0.01

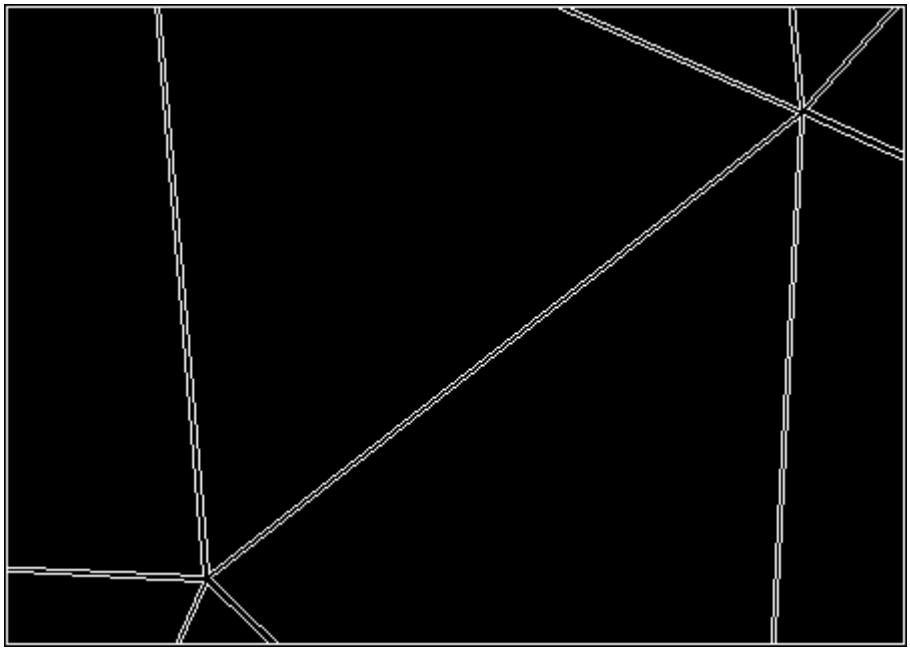

31.1.1.3. Creating and Using Mesh Plot Definitions

You can create named mesh plot definitions and save them for later use. See Creating and Using Contour Plot Definitions (p. 1762) for additional information on graphics object definitions.

The steps for creating and using mesh plot definitions are similar to the steps for Generating Mesh or Outline Plots (p. 1750), with the addition of a field for naming the mesh plot definition.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.1.2. Displaying Contours and Profiles

ANSYS Fluent enables you to plot contour lines or profiles superimposed on the physical domain. Contour lines are lines of constant magnitude for a selected variable (isotherms, isobars, and so on). A profile plot draws these contours projected off the surface along a reference vector by an amount proportional to the value of the plotted variable at each point on the surface. Sample plots are shown in Figure 31.11: Contours of Static Pressure (p. 1756) and Figure 31.12: Profile Plot of y Velocity (p. 1756).

For information about displaying contours or profiles on a surface that sweeps through the domain, see Displaying Results on a Sweep Surface (p. 1782).

Figure 31.11: Contours of Static Pressure

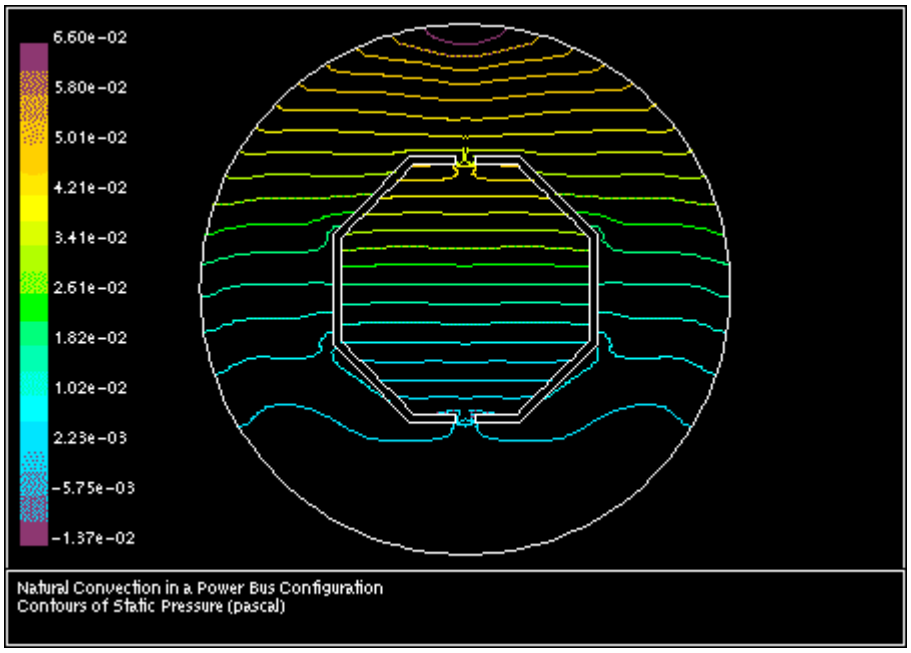

Figure 31.12: Profile Plot of y Velocity

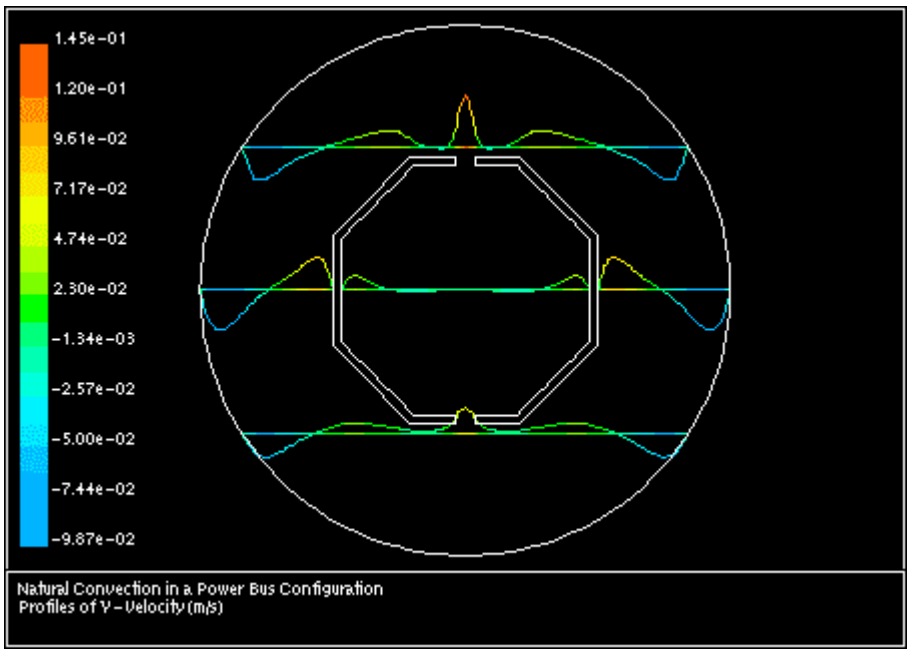


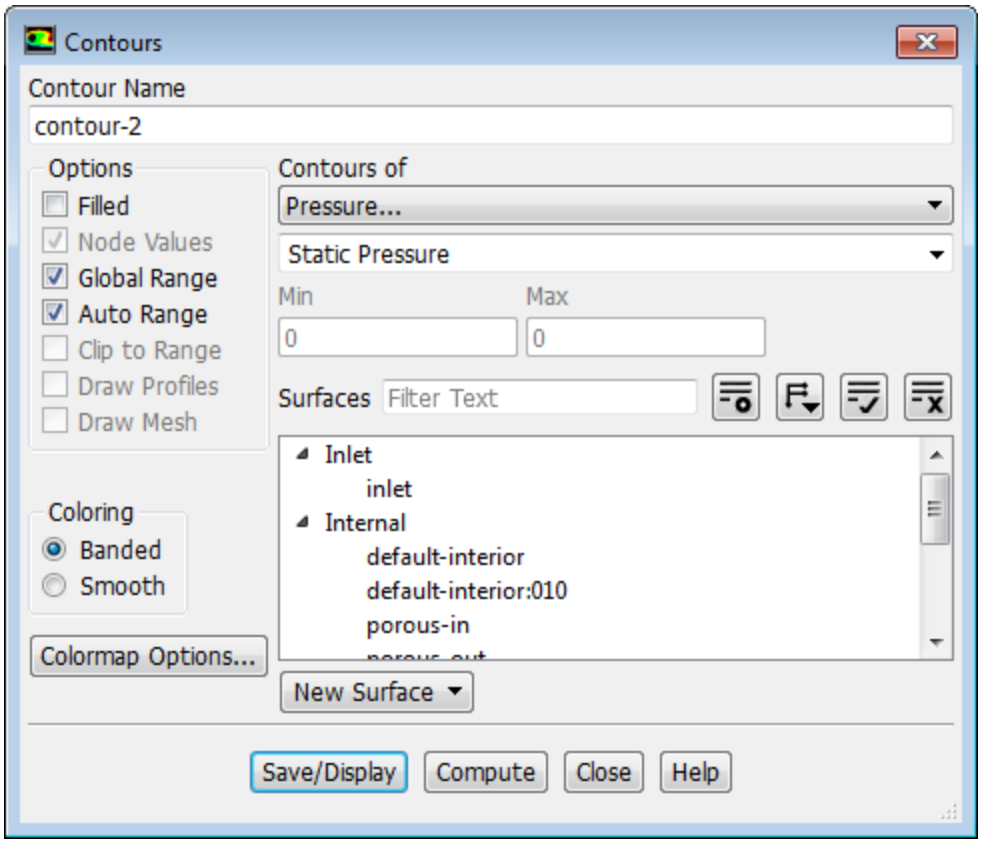
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.1.2.1. Generating Contour and Profile Plots

You can plot contours or profiles using the Contours Dialog Box (p. 2676) (Figure 31.13: The Contours Dialog Box (p. 1757)).

Results → Graphics → Contours Edit...

Figure 31.13: The Contours Dialog Box



The basic steps for generating a contour or profile plot are as follows:

1. Select the variable or function to be contoured or profiled in the **Contours of** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

2. Choose the surface or surfaces on which to draw the contours or profiles in the **Surfaces** list. For 2D cases, if no surface is selected, contouring or profiling is done on the entire domain. For 3D cases, you must always select at least one surface.

   If you want to select several surfaces of the same type, click and select **Surface Type** under **Group By**, which organizes the surfaces in a tree view that is grouped by surface type.

   Another shortcut is to use the **Filter Text** entry box to filter the **Surfaces** list to show only the surfaces that match the pattern you enter. For additional information on using the **Filter Text** entry box, see Filter Text Entry Boxes (p. 15).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Specify the number of contours or profiles in the **Levels** field. The maximum number of levels allowed is 100.

4. If you are generating a profile plot, enable the **Draw Profiles** option. In the resulting Profile Options Dialog Box (p. 2556) (Figure 31.14: The Profile Options Dialog Box (p. 1758)) you will define the profiles.

Figure 31.14: The Profile Options Dialog Box

   a. Set the "zero height" reference value for the profile (**Reference Value**) and the length scale factor for projection (**Scale Factor**). Any point on the profile with a value equal to the **Reference Value** will be plotted exactly on the defining surface. Values greater than the **Reference Value** will be projected ahead of the surface (in the direction of **Projection Dir.**) and scaled by **Scale Factor**), and values less than the **Reference Value** will be projected behind the surface and scaled.

      These parameters can be used to create fuller profiles when you need to display the variation in a variable that is small compared to the absolute value of the variable. Consider, for example, the display of temperature profiles when the temperature range in the domain is from 300 K to 310 K. The 10 K range in the temperature will be hard to detect when profiles are drawn using the default scaling (which will be based on the absolute magnitude of 310 K). To create a fuller profile, you can set the **Reference Value** to 300 and the profile **Scaling Factor** to 5 (for example) to magnify the display of the remaining 10 K range. In subsequent display of the profiles, the reference value of 300 will be effectively subtracted from the data before display so that the temperatures of 300 K will not be offset from the baselines. The profiles will then reflect only the variation of temperature from 300 K.

   b. Set the direction in which profiles are projected (**Projection Dir.**). In 2D, for example, a contour plot of pressure on the entire domain can be projected in the z direction to form a carpet plot, or a contour plot of y velocity on a sequence of y-coordinate slice lines can be projected in the y direction to form a series of velocity profiles (as shown in Figure 31.12: Profile Plot of y Velocity (p. 1756)).

   c. Click **Apply** and close the Profile Options Dialog Box (p. 2556).

5. Set any of the contour and profile plot options described below.

6. Click **Display** to draw the specified contours or profiles in the active graphics window.

The resulting display will include the specified number of contours or profiles of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

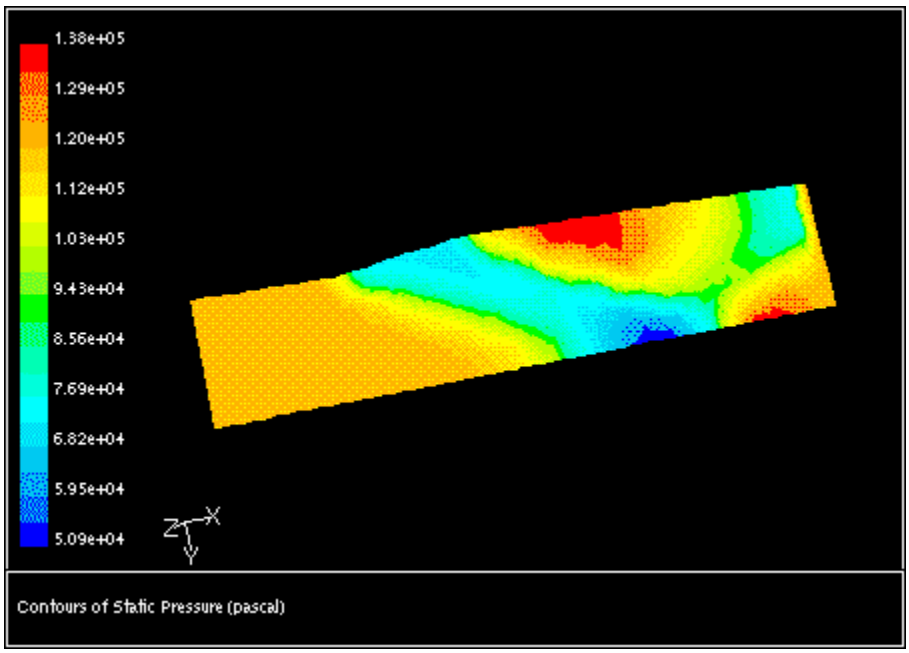
31.1.2.2. Contour and Profile Plot Options

The options mentioned in the procedure above include drawing color-filled contours/profiles (instead of the default line contours/profiles), specifying a range of values to be contoured or profiled, including portions of the mesh in the contour or profile display, choosing node or cell values for display, and storing the contour or profile plot settings.

31.1.2.2.1. Drawing Filled Contours or Profiles

Color-filled contour or profile plots show a contour or profile display containing a continuous color display (see Figure 31.15: Filled Contours of Static Pressure (p. 1759)), instead of just drawing lines representing specific values. Note that a color-filled profile display is often referred to as a "carpet plot". To generate a filled contour or profile plot, enable the **Filled** option in the Contours Dialog Box (p. 2676) during step 5 in the previous section.

Figure 31.15: Filled Contours of Static Pressure



To display smoothly shaded filled contours, you must enable lighting and select a lighting interpolation method other than **Flat** in the Display Options Dialog Box (p. 2573) or the Lights Dialog Box (p. 2588). You will not get smooth shading of filled contours if the **Clip to Range** option is turned on. Smooth shading of filled profiles is not available.

Note

The **Draw Profile** option settings are not saved with the contour plot definition. Once the dialog box is closed these options will revert to being disabled.

31.1.2.2.2. Specifying the Range of Magnitudes Displayed

By default, the minimum and maximum values contoured or profiled are set based on the range of values in the entire domain. This means that the color scale will start at the smallest value in the domain (shown in the **Min** field) and end at the largest value (shown in the **Max** field). If you are plotting contours or profiles on a subset of the domain (that is, on a surface), your plot may cover only the midrange of

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the color scale. For example, if blue corresponds to 0 and red corresponds to 10, and the values on your surface range only from 4 to 6, your plot will contain mostly green contours or profiles, since green is the color at the middle of the default color scale.

- To focus in on a smaller range of values, so that blue corresponds to 4 and red to 6, manually reset the range to be displayed. You can also use the minimum and maximum values on the selected surfaces—rather than in the entire domain—to determine the range. Another reason to manually set the range is if you are interested only in certain values. For example, if you want to determine the region where pressure exceeds a certain value, you can increase the minimum value for display so that the lower pressure values are not displayed.

- To manually set the contour/profile range, turn off the **Auto Range** option in the Contours Dialog Box (p. 2676). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be displayed.

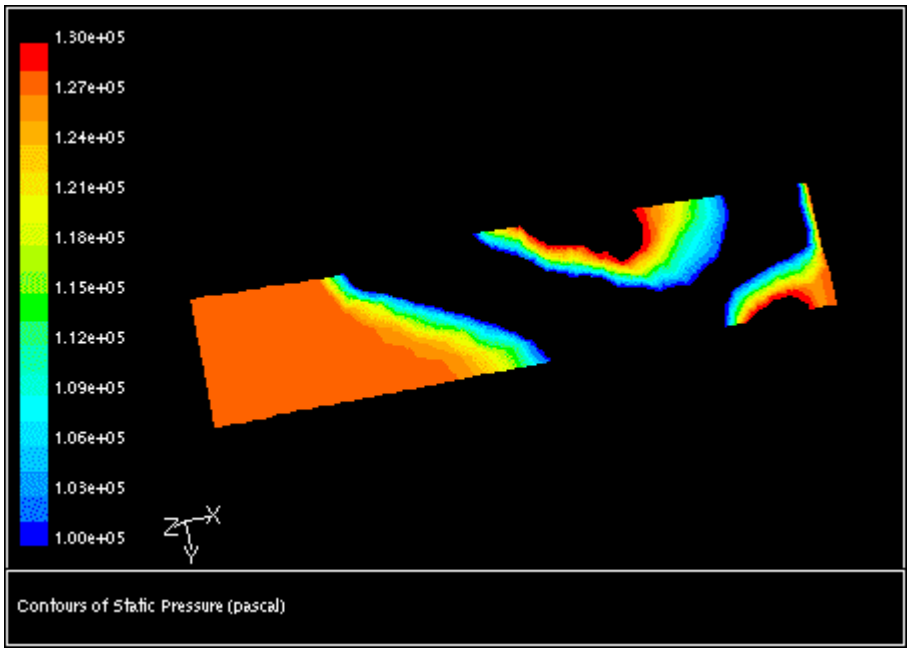
  – To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

  – If you are drawing filled contours or profiles you can control whether or not values outside the prescribed **Min**/ **Max** range are displayed.

- To leave areas in which the value is outside the specified range empty (that is, draw no contours or profiles), enable the **Clip to Range** option. This is the default setting. If you turn **Clip to Range** off, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. Figure 31.16: Filled Contours with Clip to Range On (p. 1760) and Figure 31.17: Filled Contours with Clip to Range Off (p. 1761) show the results of enabling/disabling the **Clip to Range** option.

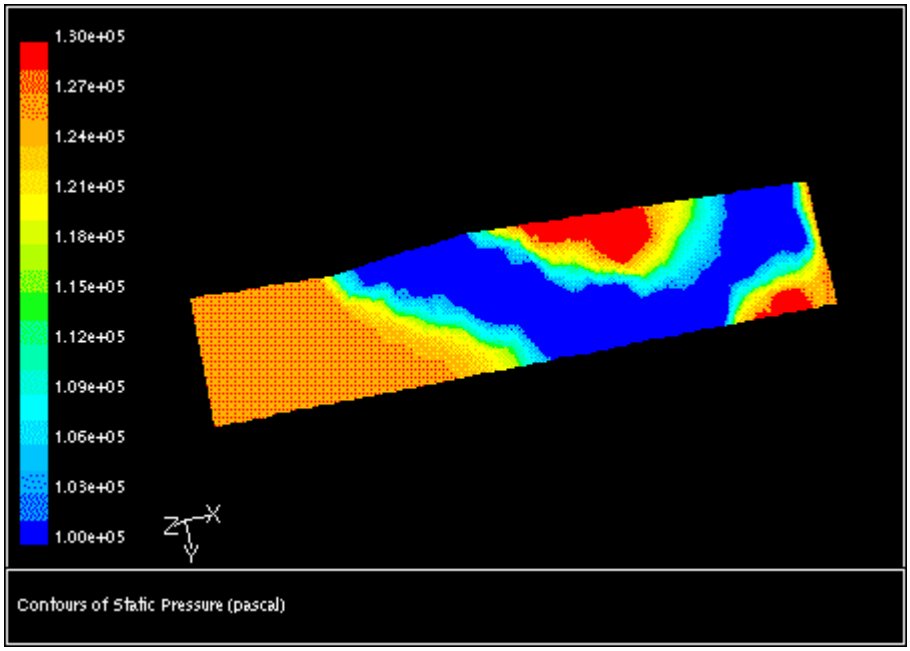
- To base the minimum and maximum values on the range of values on the selected surfaces, rather than in the entire domain, turn off the **Global Range** option in the Contours Dialog Box (p. 2676). The **Min** and **Max** values will be updated when you next click **Compute** or **Display**.

Figure 31.16: Filled Contours with Clip to Range On



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.17: Filled Contours with Clip to Range Off



31.1.2.2.3. Including the Mesh in the Contour Plot

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your contour or profile plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the contours. This is accomplished by turning on the **Draw Mesh** option in the Contours Dialog Box (p. 2676). The Mesh Display Dialog Box (p. 2163) will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the Contours Dialog Box (p. 2676), the mesh display, as defined in the Mesh Display Dialog Box (p. 2163), will be included in the contour or profile plot.

Note

The **Draw Mesh** option settings are not saved with the contour plot definition. Once the dialog box is closed these options will revert to being disabled.

To include the mesh with a contour plot that will be persisted with the case file, you can create a mesh plot definition and include both the mesh and contour plots in a scene. See Displaying a Scene (p. 1780) for more details.

31.1.2.2.4. Choosing Node or Cell Values

In ANSYS Fluent you can choose to display the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are displayed. For line contours or profiles, node values are always used. To display filled contours or profiles and to display the cell values, turn off the **Node Values** option. Filled contours/profiles of node values will show a smooth gradation of color, while filled contours/profiles of cell values may show sharp changes in color from one cell to the next.

For face-only functions (for example, **Wall Shear Stress**), the cell values that are displayed for boundary zone surfaces will actually be the face values. This is only true in the case of boundary zone surfaces created for postprocessing, where the actual cell values are used for the part of the surface that lies in

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the interior. These face values are more accurate, as face-only functions are computed on the faces and not on the cells. For more information about cell values, see Cell Values (p. 1931).

If you are plotting contours to show the effect of a porous medium or 2D fan boundary, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

31.1.2.2.5. Storing Contour Plot Settings

For frequently used combinations of contour variables and options, you can store the information needed to generate the contour plot as follows:

1. In the Contours Dialog Box (p. 2676), specify a **Setup** number.
2. Set up the desired information in the Contours Dialog Box (p. 2676).
3. Click **Display**.

   The settings for **Options**, **Contours of**, **Min**, **Max**, and **Surfaces** will be saved.

You can then change the **Setup** number to an unused value (that is, an ID for which no information has been saved) and generate a different contour plot.

To generate a plot using the saved setup information:

1. Change the **Setup** number back to the value for which you saved contour information.
2. Click **Display**.

You can save up to 10 different setups.

Important

Note that the number of contour **Levels**, the surfaces selected for display in the Mesh Display Dialog Box (p. 2163) (when the **Draw Mesh** option is activated), and the settings for profiles in the Profile Options Dialog Box (p. 2556) (when the **Draw Profiles** option is activated) will *not* be saved in the **Setup**, nor will the **Setup** be saved in the case file.

31.1.2.3. Creating and Using Contour Plot Definitions

You can create named contour plot definitions and save them for later use. This could be useful for demonstration purposes, scene creation, or for postprocessing the results of your simulation when varying the settings between runs (to name a few examples).

The number of contour plot definitions is not limited.

To create a contour plot definition:

Results → **Graphics** → **Contours** → **New...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Contours Dialog Box (p. 2676), in the **Contour Name** text entry box, enter the name for your contour plot definition (or accept the default name `contour-`*`id`*).

   Important

   Contour and vector plot definitions must have unique names.

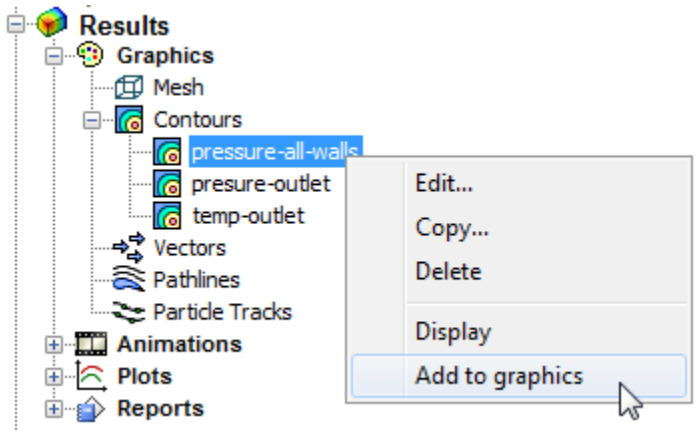
2. Set contour parameters and options.

   The **Draw Mesh** *and* **Draw Profile** *option settings are not saved with the contour plot definition. Once the dialog box is closed these options will revert to being disabled.*

3. Click **Save/Display**.

   The specified contour will be displayed in the active graphics window, and the new contour plot definition with the name you have entered will appear in the tree under **Contours**.

Once the contour plot definition is created, you can perform the following actions using the right-click menu commands:



- Edit the existing contour plot definition.
- Copy the contour plot definition.

  When creating a copy of the existing contour, you can modify contour settings in the **Contours** dialog box that will open.

- Delete the selected contour plot definition.
- Display the contour in the graphics window.
- Add the selected contour to the plot in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that while **Display** replaces the current contents of the graphics window, **Add to graphics** preserves the current graphics window contents.

Note

- You can move the colormap of contour plot definitions by left-clicking and dragging it to the desired location. The colormap can also be resized by dragging the corners of the box that appears when you hover over the colormap. *The colormap location is not saved with the contour plot definition.*
- For 2D cases, Fluent automatically creates a new surface when you click **Save/Display** in the **Contours** dialog box, if you have not selected any surfaces for display. New surfaces are only created for fluid zones that do not already have a surface defined.

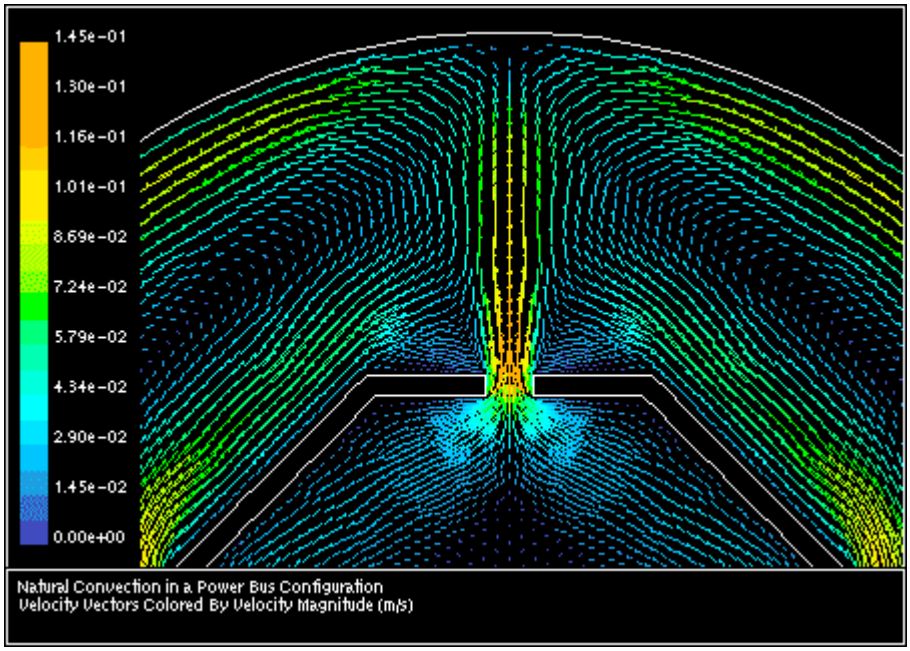
These commands are also available through the text user interface (`display/objects`).

31.1.3. Displaying Vectors

You can draw vectors in the entire domain, or on selected surfaces. By default, one vector is drawn at the center of each cell (or at the center of each facet of a data surface), with the length and color of the arrows representing the velocity magnitude (Figure 31.18: Velocity Vector Plot (p. 1764)). The spacing, size, and coloring of the arrows can be modified, along with several other vector plot settings. Velocity vectors are the default, but you can also plot vector quantities other than velocity. Note that cell-center values are always used for vector plots; you cannot plot node-averaged values.

For information about displaying vectors on a surface that sweeps through the domain, see Displaying Results on a Sweep Surface (p. 1782).

Figure 31.18: Velocity Vector Plot



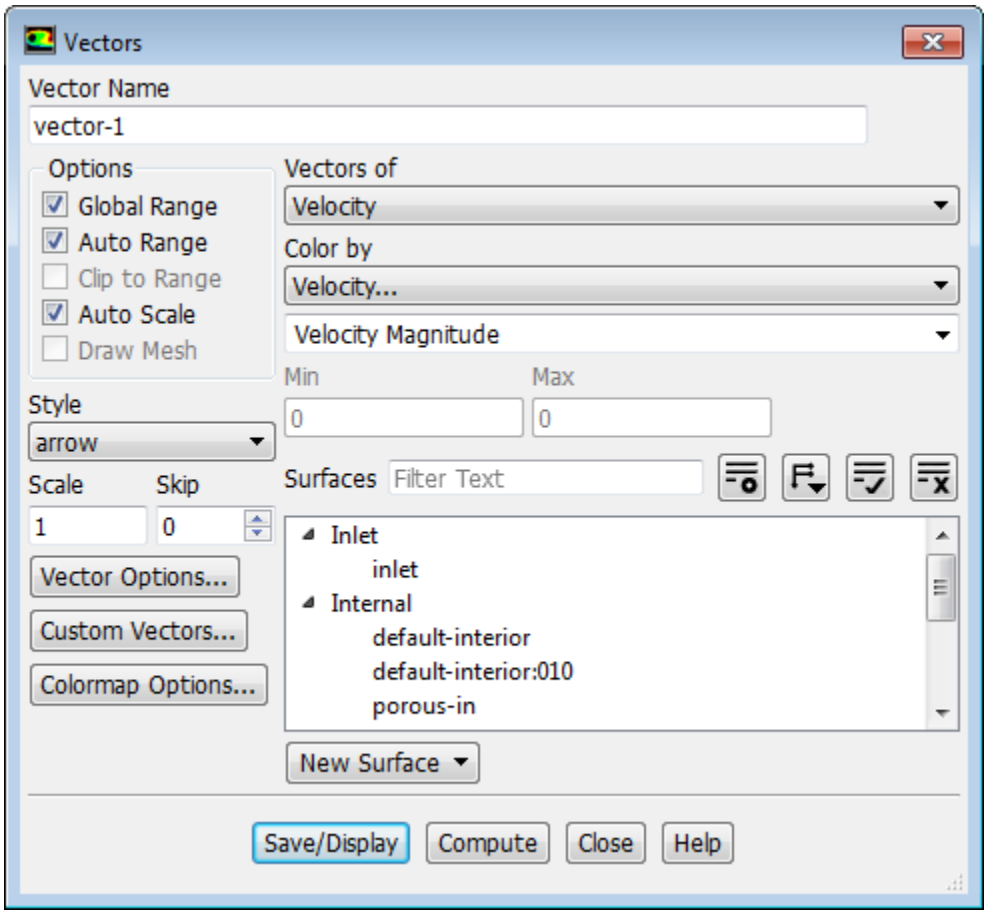
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.1.3.1. Generating Vector Plots

You can plot vectors using the Vectors Dialog Box (p. 2831) (Figure 31.19: The Vectors Dialog Box (p. 1765)).

Results → Graphics → Vectors **Edit...**

Figure 31.19: The Vectors Dialog Box



The procedure for generating a vector plot is as follows:

1. In the **Vectors of** drop-down list, select the vector quantity to be plotted. By default, only velocity and relative velocity are available, but you can create your own custom vectors as described in Creating and Managing Custom Vectors (p. 1769). Additional vector options are available for adjoint solver results, as described in Field Data (p. 2102).

2. In the **Surfaces** list, choose the surface(s) on which you want to display vectors. If you want to display vectors on the entire domain, select none of the surfaces in the list.

   If you want to select several surfaces of the same type, click and select **Surface Type** under **Group By**, which organizes the surfaces in a tree view that is grouped by surface type.

   Another shortcut is to use the **Filter Text** entry box to filter the **Surfaces** list to show only the surfaces that match the pattern you enter. For additional information on using the **Filter Text** entry box, see Filter Text Entry Boxes (p. 15).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Set any of the vector plot options as described in Vector Plot Options (p. 1766).

4. Click **Display** to draw the vectors in the active graphics window.

31.1.3.2. Displaying Relative Velocity Vectors

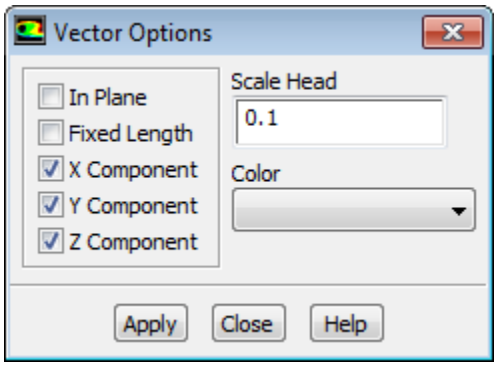
If you are solving your problem using one or more moving reference frames or moving meshes, you will have the option to display either the absolute vectors or the relative vectors. If you select **Velocity** (the default) in the **Vectors of** list, the vectors will be drawn based on the absolute, stationary reference frame. If you select **Relative Velocity**, the vectors will be drawn based on the reference frame of the **Reference Zone** in the Reference Values Task Page (p. 2502). See Setting the Reference Zone (p. 1927) for details. (If you are modeling a single moving reference frame, you need not specify the **Reference Zone**; the vectors will be drawn based on the moving reference frame.)

31.1.3.3. Vector Plot Options

The options mentioned in the procedure above include scaling the vector arrows, skipping the display of some vectors, displaying vectors in the plane of the data surface, displaying fixed-length or fixed-color vectors, displaying directional components of the vectors, specifying a range of values to be displayed, coloring the vectors by a different scalar field, including portions of the mesh in the vector display, and changing the style of the arrows or the scale of the arrowheads.

The most common options are set in the Vectors Dialog Box (p. 2831), and others are set in the Vector Options Dialog Box (p. 2557) (Figure 31.20: The Vector Options Dialog Box (p. 1766)), which you can open by clicking **Vector Options...** in the Vectors Dialog Box (p. 2831).

Figure 31.20: The Vector Options Dialog Box



31.1.3.3.1. Scaling the Vectors

By default, vectors are scaled automatically so that the arrows overlap minimally when no vectors are skipped. For instructions on thinning the vector display, see "Thinning" Pathlines (p. 1775). With the **Auto Scale** option, you can modify the **Scale** factor (which is set to 1 by default) to increase or decrease the vector scale from the default "auto scale". The main advantage of autoscaling is that the vector display with a scale factor of 1 will always be appropriate, regardless of the size of the domain, giving you a better starting point for fine-tuning the vector scale.

If you turn off the **Auto Scale** option, the vectors will be drawn at their actual sizes scaled by the scale factor (**Scale**, which is set to 1 by default). The "actual" size of a vector is the magnitude of the vector variable (velocity, by default) at the point where it is drawn. A vector drawn at a point where the velocity magnitude is 100 m/s is drawn 100 m long, whether the domain is 0.1 m or 1000 m. You can modify

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the vector scale by changing the value of **Scale** in the Vectors Dialog Box (p. 2831) until the size of the vectors (that is, the actual size multiplied by **Scale**) is satisfactory.

31.1.3.3.2. Skipping Vectors

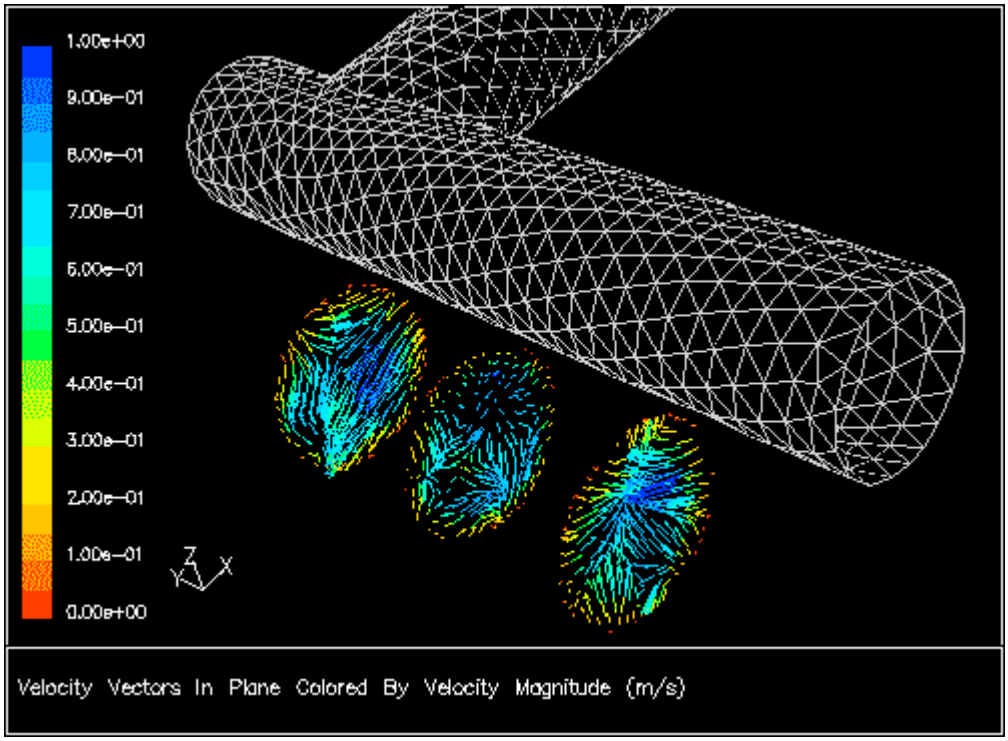
If your vector display is difficult to understand because there are too many arrows displayed, you can "thin out" the vectors by changing the **Skip** value in the Vectors Dialog Box (p. 2831). By default, **Skip** is set to 0, indicating that a vector will be drawn for each cell in the domain or for each face on the selected surface (for example, n vectors). If you increase **Skip** to 1, every other vector will be displayed, yielding $n/2$ vectors. If you increase **Skip** to 2, every third vector will be displayed, yielding $n/3$ vectors, and so on. The order of faces on the selected surface (or cells in the domain) will determine which vectors are skipped or drawn; therefore adaption will change the appearance of the vector display when a nonzero **Skip** value is used.

31.1.3.3.3. Drawing Vectors in the Plane of the Surface

For some problems, you may be interested in visualizing velocity (or other vector) components that are normal to the flow. These "secondary flow" components are usually much smaller than the components in the flow direction and are difficult to see when the flow direction components are also visible. To easily view the normal flow components, you can enable the **In Plane** option in the Vector Options Dialog Box (p. 2557). When this option is on, ANSYS Fluent will display only the vector components in the plane of the surface selected for display. If the selected surface is a cross-section of the flow domain, you will be displaying the components normal to the flow.

Figure 31.21: Velocity Vectors Generated Using the In Plane Option (p. 1767) shows velocity vectors generated using the **In Plane** option. Note that these vectors have been translated outside the domain, as described in Transforming Geometric Objects in a Scene (p. 1819), so that they can be seen more easily.

Figure 31.21: Velocity Vectors Generated Using the In Plane Option



31.1.3.3.4. Displaying Fixed-Length Vectors

By default, the length of a vector is proportional to its velocity magnitude. If you want all of the vectors to be displayed with the same length, you can enable the **Fixed Length** option in the Vector Options Dialog Box (p. 2557). To modify the vector length, adjust the value of the **Scale** factor in the Vectors Dialog Box (p. 2831).

31.1.3.3.5. Displaying Vector Components

All Cartesian components of the vectors are drawn by default, so that the arrow points along the resultant vector in physical space. However, sometimes one of the components, say, the x component, is relatively large. In such cases, you may want to suppress the x component and scale up the vectors, in order to visualize the smaller y and z components. To suppress one or more of the vector components, turn off the appropriate button(s) (**X**, **Y**, or **Z Component**) in the Vector Options Dialog Box (p. 2557).

31.1.3.3.6. Specifying the Range of Magnitudes Displayed

By default, the minimum and maximum vectors included in the vector display are set based on the range of vector-variable (velocity, by default) magnitudes in the entire domain. If you want to focus in on a smaller range of values, you can restrict the range to be displayed. The color scale for the vector display will change to reflect the new range of values. (You can also use the minimum and maximum values on the selected surfaces—rather than on the entire domain—to determine the range, or change the scalar field by which the vectors are colored from velocity magnitude to any other scalar, as described below.)

To manually set the range of velocity magnitudes (or the range of whatever scalar field is selected in the **Color by** drop-down list), turn off the **Auto Range** option in the Vectors Dialog Box (p. 2831). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be displayed. For example, if you want to display velocity vectors only in regions where the velocity magnitude exceeds 150 m/s but is less than 300 m/s, you will change the value of **Min** to 150 and the value of **Max** to 300. Similarly, if you are coloring the vectors by static pressure, you can choose to display velocity vectors only in regions where the pressure is within a specified range. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

When you restrict the range of vectors displayed, you can also control whether or not values outside the prescribed **Min**/ **Max** range are displayed. To leave areas in which the value is outside the specified range empty (that is, draw no vectors), enable the **Clip to Range** option. This is the default setting. If you turn **Clip to Range** off, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. This feature is the same as the one available for displaying filled contours (see Figure 31.16: Filled Contours with Clip to Range On (p. 1760) and Figure 31.17: Filled Contours with Clip to Range Off (p. 1761)).

You can also choose to base the minimum and maximum values on the range of values on the selected surfaces, rather than the entire domain. To do this, turn off the **Global Range** option in the Vectors Dialog Box (p. 2831). The **Min** and **Max** values will be updated when you next click **Compute** or **Display**.

31.1.3.3.7. Changing the Scalar Field Used for Coloring the Vectors

If you want to color the vectors by a scalar field other than velocity magnitude (the default), you can select a different variable or function in the **Color by** drop-down list. Select the desired category in the upper list, and then choose one of the related quantities from the lower list. If you choose static pressure, for example, the length of the vectors will still correspond to the velocity magnitude, but the color of the vectors will correspond to the value of pressure at each point where a vector is drawn.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.1.3.3.8. Displaying Vectors Using a Single Color

If you want all of the vectors to be the same color, you can select the color to be used in the **Color** drop-down list in the Vector Options Dialog Box (p. 2557). If no color is selected (that is, if you choose the empty space at the top of the drop-down list—the default selection), the vector color will be determined by the **Color by** field specified in the Vectors Dialog Box (p. 2831). Single color vectors are useful in displays that overlay contours and vectors.

31.1.3.3.9. Including the Mesh in the Vector Plot

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your vector plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the vectors. This is accomplished by turning on the **Draw Mesh** option in the Vectors Dialog Box (p. 2831). The Mesh Display Dialog Box (p. 2163) will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the Vectors Dialog Box (p. 2831), the mesh display, as defined in the Mesh Display Dialog Box (p. 2163), will be included in the vector plot.

Note

The **Draw Mesh** option settings are not saved with the vector plot definition. Once the dialog box is closed these settings will revert to being disabled.

To include the mesh with a vector plot that will be persisted with the case file, you can create a mesh plot definition and include both the mesh and vector plots in a scene. See Displaying a Scene (p. 1780) for more details.

31.1.3.3.10. Changing the Arrow Characteristics

There are five different styles available for drawing the vector arrows. Choose **cone**, **filled-arrow**, **arrow**, **harpoon**, or **headless** in the **Style** drop-down list in the Vectors Dialog Box (p. 2831). The default arrow style is **harpoon**.

If you choose a vector arrow style that includes heads, you can control the size of the arrowhead by modifying the **Scale Head** value in the Vector Options Dialog Box (p. 2557).

31.1.3.4. Creating and Managing Custom Vectors

In addition to the velocity vector quantity provided by ANSYS Fluent, you can also define your own custom vectors to be plotted. This capability is available with the Custom Vectors Dialog Box (p. 2558).

Any custom vectors that you define will be saved in the case file the next time that you save it. You can also save your custom vectors to a separate file, so that they can be used with a different case file.

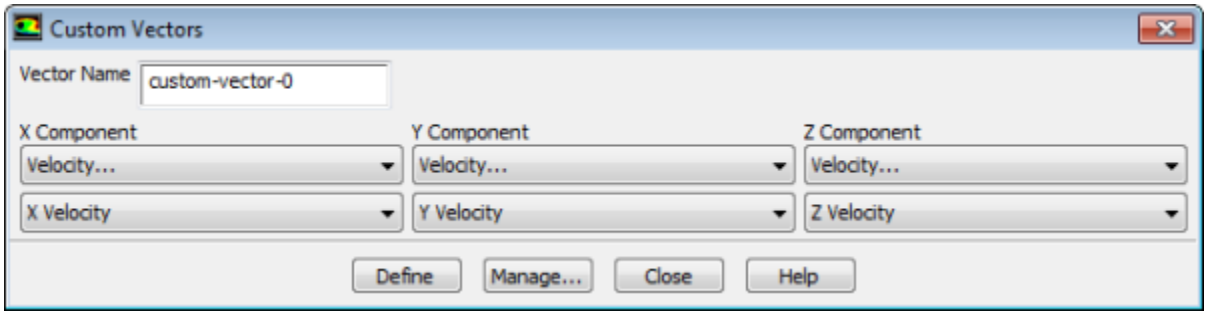
31.1.3.4.1. Creating Custom Vectors

To create your own custom vector, you will use the Custom Vectors Dialog Box (p. 2558) (Figure 31.22: The Custom Vectors Dialog Box (p. 1770)). This dialog box enables you to define custom vectors based on existing quantities. Any vectors that you define will be added to the **Vectors of** list in the Vectors Dialog Box (p. 2831).

To open the Custom Vectors Dialog Box (p. 2558), click **Custom Vectors...** in the Vectors Dialog Box (p. 2831).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.22: The Custom Vectors Dialog Box



The steps for creating a custom vector are as follows:

1. Specify the name of the custom vector in the **Vector Name** field.

   Important

   Do not specify a name that is already used for a standard vector (for example, `velocity` or `relative-velocity`).

2. Select the variable or function for the *x* component of the vector in the **X Component** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. For an explanation of the variables in the list, see Field Function Definitions (p. 1931).

3. Repeat the step above to select the variable or function for the y component (and, in 3D, the z component) of the custom vector.

   Important

   You can use the **Custom Vectors** option to plot vectors in solid cell zones. The scalars that are selected in the *x*, *y* (and, in 3D, the *z*) components, and that are valid in solid regions, will have vector plots displayed in the solid cell zones. Note that if a vector has no valid components in the solid region, then that vector will not be plotted in the solid region. However, if at least one component of the vector is valid in the solid region, then only that component of the vector will be plotted.

4. Click **Define**.

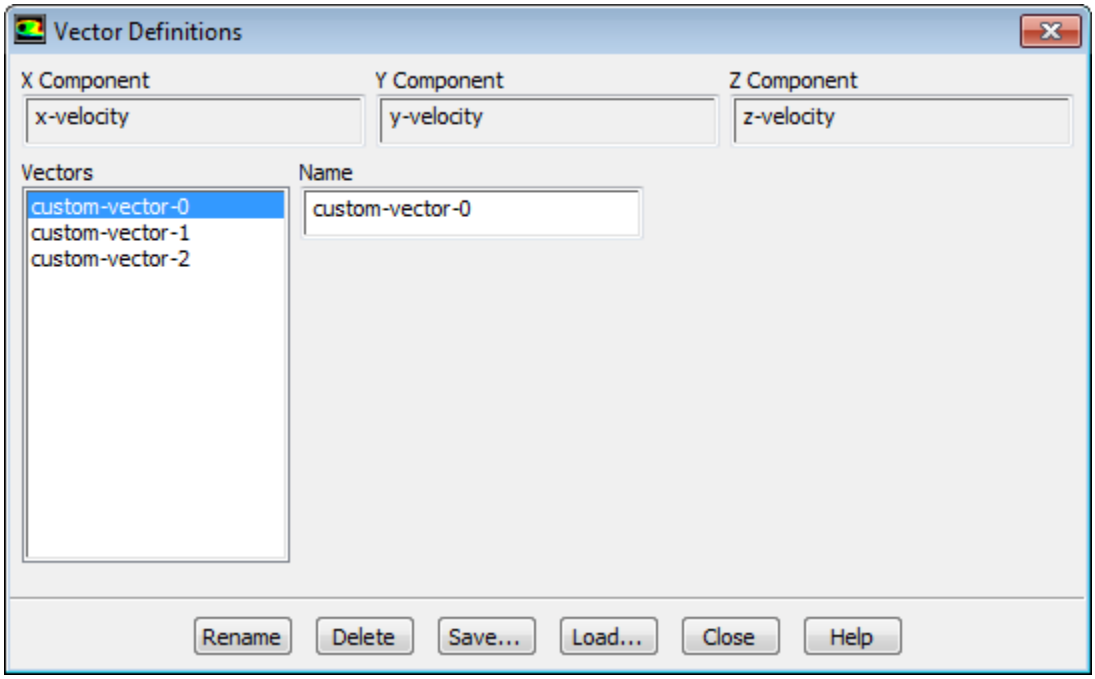
31.1.3.4.2. Manipulating, Saving, and Loading Custom Vectors

Once you have defined your vectors, you can manipulate them using the Vector Definitions Dialog Box (p. 2558) (Figure 31.23: The Vector Definitions Dialog Box (p. 1771)). You can display a vector definition to be sure that it is correct, delete the vector if you decide that it is incorrect and must be redefined, or give the vector a new name. You can also save custom vectors to a file or read them from a file. The custom vector file enables you to transfer custom vectors between case files.

To open the Vector Definitions Dialog Box (p. 2558), click **Manage...** in the Custom Vectors Dialog Box (p. 2558).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.23: The Vector Definitions Dialog Box



The following actions can be performed in the Vector Definitions Dialog Box (p. 2558):

- To check the definition of a vector, select it in the **Vectors** list. Its definition will be displayed in the **X Component**, **Y Component**, and **Z Component** fields at the top of the dialog box. This display is for informational purposes only; you cannot edit it. If you want to change a vector definition, you must delete the vector and define it again in the Custom Vectors Dialog Box (p. 2558).
- To delete a vector, select it in the **Vectors** list and click **Delete**.
- To rename a vector, select it in the **Vectors** list, enter a new name in the **Name** field, and click **Rename**.

Important

Do not specify a name that is already used for a standard vector (for example, `velocity` or `relative-velocity`).

- To save all the vectors in the **Vectors** list to a file, click **Save...** and specify the file name in The Select File Dialog Box (p. 19).
- To read custom vectors from a file that you saved as described above, click **Load** and specify the file name in The Select File Dialog Box (p. 19). (Custom vectors are valid Scheme functions, and can also be loaded with the **File/Read/Scheme...** ribbon tab item, as described in Reading Scheme Source Files (p. 57).)

31.1.3.5. Creating and Using Vector Plot Definitions

You can create named vector plot definitions and save them for later use. See Creating and Using Contour Plot Definitions (p. 1762) for additional information on plot definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The steps for creating and using vector plot definitions are similar to the steps for Generating Vector Plots (p. 1765), with the addition of a field for naming the vector plot definition.

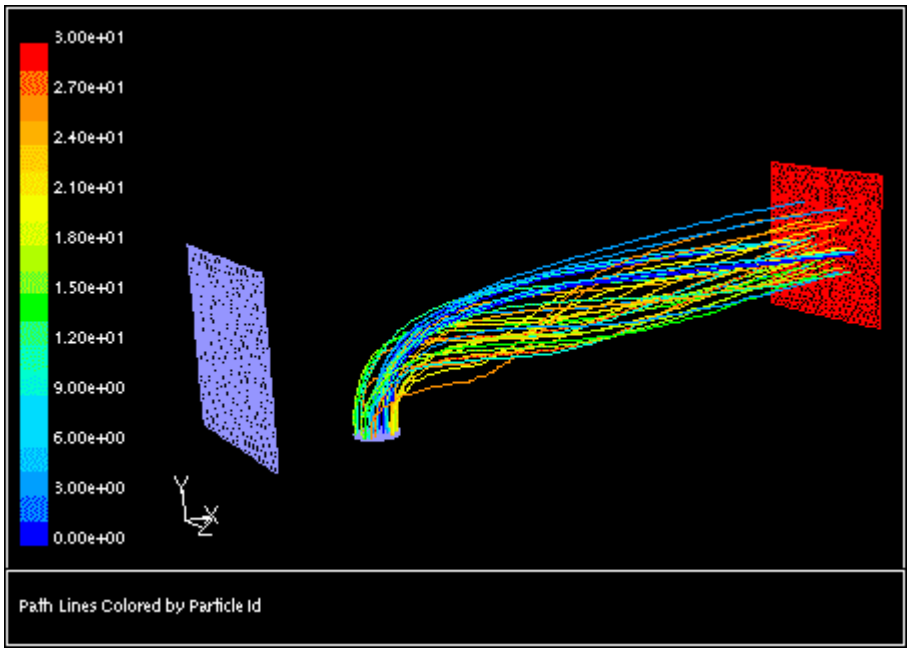
Note

You can move the colormap of a vector plot definition by left-clicking and dragging it to the desired location. The colormap can also be resized by dragging the corners of the box that appears when you hover over the colormap. *The colormap location is not saved with the vector plot definition.*

31.1.4. Displaying Pathlines

Pathlines are used to visualize the flow of massless particles in the problem domain. The particles are released from one or more surfaces that you have created by clicking **Create** in the **Surface** group box of the **Setting Up Domain** ribbon tab (see Creating Surfaces and Cell Registers for Displaying and Reporting Data (p. 1709)). A **line** or **rake** surface (see Line and Rake Surfaces (p. 1718)) is most commonly used. Figure 31.24: Pathline Plot (p. 1772) shows a sample plot of pathlines.

Figure 31.24: Pathline Plot



Note that the display of discrete-phase particle trajectories is discussed in Displaying of Trajectories (p. 1330).

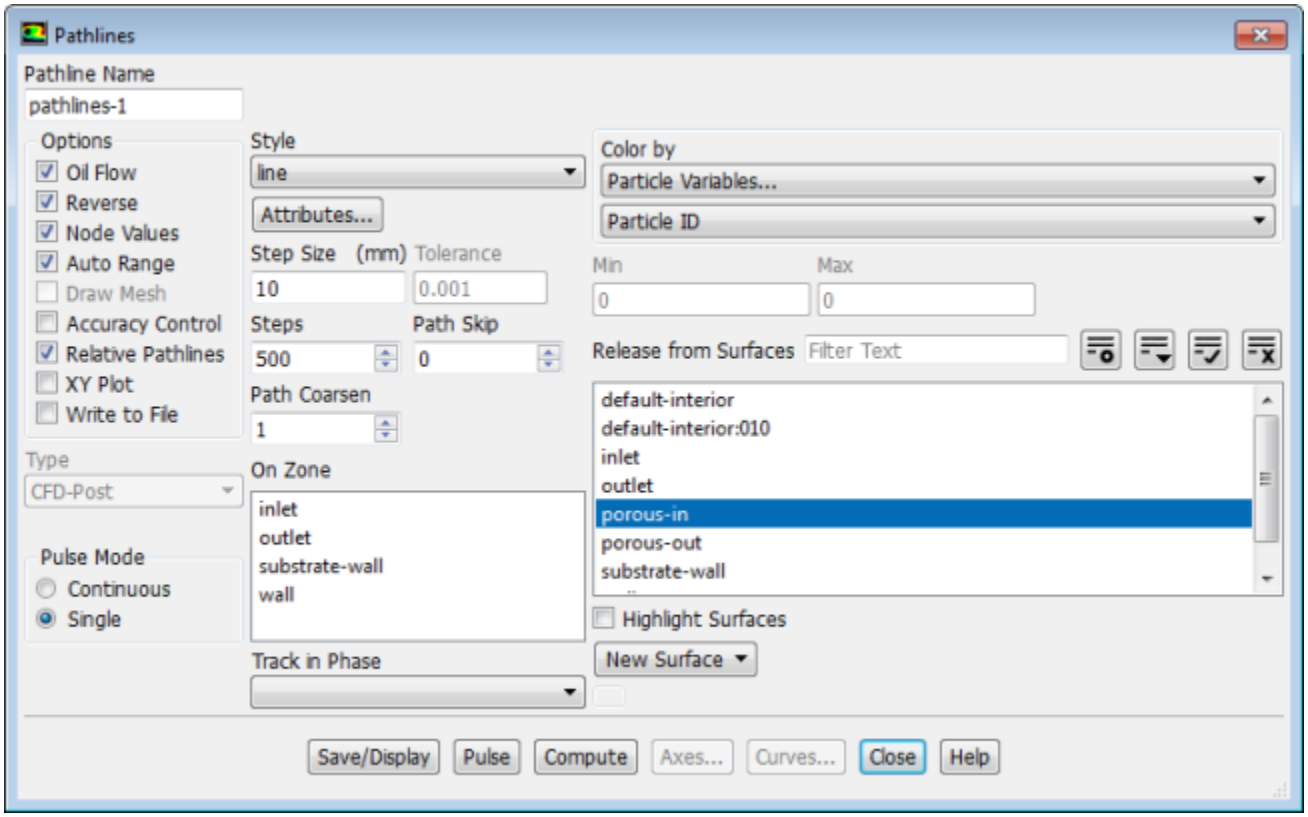
31.1.4.1. Steps for Generating Pathlines

You can plot pathlines using the Pathlines Dialog Box (p. 2771) (Figure 31.25: The Pathlines Dialog Box (p. 1773)).

Results → Graphics → Pathlines → Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.25: The Pathlines Dialog Box



The basic steps for generating pathlines are as follows:

1. Select the surface(s) from which to release the particles in the **Release From Surfaces** list.

2. (Eulerian Multiphase model only) From the **Track in Phase** drop-down list, select the phase in which pathlines will be tracked. If you want to track pathlines in the mixture of all phases, select **all-phase**. By default, particles are tracked in the primary phase.

3. Set the step size and the maximum number of steps. The **Step Size** sets the length interval used for computing the next position of a particle. Note that particle positions are always computed when particles enter/leave a cell; even if you specify a very large step size, the particle positions at the entry/exit of each cell will still be computed and displayed. The value of **Steps** sets the maximum number of steps a particle can advance. A particle will stop when it has traveled this number of steps or when it leaves the domain. One simple rule of thumb to follow when setting these two parameters is that if you want the particles to advance through a domain of length L, the **Step Size** times the number of **Steps** should be approximately equal to L.

4. Set any of the pathline plot options described in Options for Pathline Plots (p. 1773).

5. Click **Display** to draw the pathlines, or click **Pulse** to animate the particle positions. The **Pulse** button will become the **Stop !** button during the animation, and you must click **Stop !** to stop the pulsing.

31.1.4.2. Options for Pathline Plots

You can include the mesh in the pathline display, control the style of the pathlines (including the twisting of ribbon-style pathlines), and color them by different scalar fields and control the color scale. You can also "thin" the pathline display, trace the particle positions in reverse, and draw "oil-flow" pathlines. If you are "pulsing" the pathlines, you can control the pulse mode. If you are using larger

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

time step size for calculations then you can control the accuracy of the pathline by specifying tolerance. In addition to the regular pathline display, you can also generate an XY plot of a specified quantity along the pathline trajectories. Finally, you can choose node or cell values for display (or plotting).

31.1.4.2.1. Including the Mesh in the Pathline Display

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your pathline display as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the pathlines (as in Figure 31.24: Pathline Plot (p. 1772)). This is accomplished by turning on the **Draw Mesh** option in the Pathlines Dialog Box (p. 2771). The Mesh Display Dialog Box (p. 2163) will appear when you enable the **Draw Mesh** option, where you can set the mesh display parameters. When you click **Display** in the Pathlines Dialog Box (p. 2771), the mesh display, as defined in the Mesh Display Dialog Box (p. 2163), will be included in the plot of pathlines.

Note

The **Draw Mesh** option settings are not saved with the pathline definition. Once the dialog box is closed these settings will revert to being disabled. If you want these settings persisted within the current session, you can use the non-persistent **Pathlines** dialog box.

Postprocessing → Graphics → Pathlines → Edit...

31.1.4.2.2. Controlling the Pathline Style

Pathlines can be displayed as lines (with or without arrows), ribbons, cylinders (coarse, medium, or fine), triangles, spheres, or a set of points. You can choose **line**, **line-arrows**, **point**, **sphere**, **ribbon**, **triangle**, **coarse-cylinder**, **medium-cylinder**, or **fine-cylinder** in the **Style** drop-down list in the Pathlines Dialog Box (p. 2771). Pulsing can be done only on **point**, **sphere**, or **line** styles.

Once you have selected the pathline style, click **Style Attributes...** to set the pathline thickness and other parameters related to the selected **Style**:

- If you are using the **line** or **line-arrows** style, set the **Line Width** in the Path Style Attributes Dialog Box (p. 2559) that appears when you click **Style Attributes...**. For **line-arrows** you will also set the **Spacing Factor**, which controls the spacing between the lines. The size of the arrow heads can be adjusted by entering a value in the **Scale** text-entry box.

- If you are using the **point** style, you will set the **Marker Size** in the Path Style Attributes Dialog Box (p. 2559). The thickness of the pathline will be the thickness of the marker.

- If you are using the **sphere** style, you will set the **Diameter** and the **Detail** in the Path Style Attributes Dialog Box (p. 2559).

  The best diameter to use will depend on the dimensions of the domain, the view, and the particle density. However, an adequate starting point would be a diameter on the order of 1/4 of the average cell size or 1/4 step size. Units for the **Diameter** field correspond to the mesh dimensional units.

  The level of detail applied to the graphical rendering of the spheres can be controlled using the **Detail** field in the Path Style Attributes Dialog Box (p. 2559). The level of detail uses integer values ranging from 4 to 50. Note that the performance of the graphical rendering will be better when using a small level of detail, that is, very coarse spheres, such as 6 or 8. The rendering performance significantly decreases with higher levels of detail. You should gradually increase the detail to determine the best-case scenario between performance and quality.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Also note that to take full advantage of spherical rendering, lighting should be turned on in the view. The Gouraud setting provides much smoother looking spheres than the Flat setting and better performance than the Phong setting. For more information on lighting, see Adding Lights (p. 1796).

- If you are using the **triangle** or any of the **cylinder** styles, you will set the **Width** in the Path Style Attributes Dialog Box (p. 2559). For triangles, the specified value will be half the width of the triangle's base, and for cylinders, the value will be the cylinder's radius.

- If you are using the **ribbon** style, clicking **Style Attributes...** opens the Ribbon Attributes Dialog Box (p. 2560), in which you can set the ribbon's **Width**. You can also specify parameters for twisting the ribbon pathlines. In the **Twist By** drop-down list, you can select a scalar field on which the pathline twisting is based (for example, helicity). Select the desired category in the upper list and then select a related quantity in the lower list. The twisting may not be displayed smoothly because the scalar field by which you are twisting the pathline is calculated at cell centers only (and not interpolated to a particle's position). The **Twist Scale** sets the amount of twist for the selected scalar field. To magnify the twist for a field with very little change, increase this factor; to display less twist for a field with dramatic changes, decrease this factor.

  When you click **Compute**, the **Min** and **Max** fields will be updated to show the range of the **Twist By** scalar field.

31.1.4.2.3. Controlling Pathline Colors

By default, the pathlines are colored by the particle ID number. That is, each particle's path will be a different color. You can also choose the color based on the surface from where the pathlines were released from using the surface ID as the particle variable. You can choose to color the pathlines by any of the scalar fields in the **Color by** drop-down list. Select the desired category in the upper list and then select a related quantity in the lower list. If you color the pathlines by velocity magnitude, for example, each particle's path will be colored depending on the speed of the particle at each point in the path.

The range of values of the selected scalar field will, by default, be the upper and lower limits of that field in the entire domain. The color scale will map to these values accordingly. If you prefer to restrict the range of the scalar field, turn off the **Auto Range** option (under **Options**) and set the **Min** and **Max** values manually beneath the **Color by** list. If you color the pathlines by velocity, and you limit the range to values between 30 and 60 m/s, for example, the "lowest" color will be used when the particle speed falls below 30 m/s and the "highest" color will be used when the particle speed exceeds 60 m/s. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

31.1.4.2.4. "Thinning" Pathlines

If your pathline plot is difficult to understand because there are too many paths displayed, you can "thin out" the pathlines by changing the **Path Skip** value in the Pathlines Dialog Box (p. 2771). By default, **Path Skip** is set to 0, indicating that a pathline will be drawn from each face on the selected surface (for example, n pathlines). If you increase **Path Skip** to 1, every other pathline will be displayed, yielding $n/2$ pathlines. If you increase **Path Skip** to 2, every third pathline will be displayed, yielding $n/3$, and so on. The order of faces on the selected surface will determine which pathlines are skipped or drawn; therefore adaption will change the appearance of the pathline display when a nonzero **Path Skip** value is used.

31.1.4.2.5. Coarsening Pathlines

To further simplify pathline plots, and reduce plotting time, a coarsening factor can be used to reduce the number of points that are plotted. Providing a coarsening factor of n, will result in each n^{th} point being plotted for a given pathline in any cell. This coarsening factor is specified in the Pathlines Dialog

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Box (p. 2771), in the **Path Coarsen** field. For example, if the coarsening factor is set to 2, then ANSYS Fluent will plot alternate points.

Important

Note that if any particle or pathline enters a new cell, this point will always be plotted.

31.1.4.2.6. Reversing the Pathlines

If you are interested in determining the source of a particle for which you know the final destination (for example, a particle that leaves the domain through an exit boundary), you can reverse the pathlines and follow them from their destination back to their source. To do this, enable the **Reverse** option in the Pathlines Dialog Box (p. 2771). All other inputs for defining the pathlines will be exactly the same as for forward pathlines; the only difference is that the surface(s) selected in the **Release From Surfaces** list will be the final destination of the particles instead of their source.

31.1.4.2.7. Plotting Oil-Flow Pathlines

If you want to display "oil-flow" pathlines (that is, pathlines that are constrained to lie on a particular boundary), enable the **Oil Flow** option in the Pathlines Dialog Box (p. 2771). You will then need to select a single boundary zone in the **On Zone** list. The selected zone is the boundary on which the oil-flow pathlines will lie.

31.1.4.2.8. Controlling the Pulse Mode

If you are going to use the **Pulse** button in the Pathlines Dialog Box (p. 2771) to animate the pathlines, you can choose one of two pulse modes for the release of particles that follow the pathlines. To release a single wave of particles, select the **Single** option under **Pulse Mode**. To release particles continuously from the initial positions, select the **Continuous** option.

31.1.4.2.9. Controlling the Accuracy

If you are using large time step size for the calculation, there might be significant error introduced while calculating the pathlines. To control this error, select **Accuracy Control** and specify the value of **Tolerance**. The tolerance value will be taken in to consideration while calculating the pathlines for each time step.

31.1.4.2.10. Plotting Relative Pathlines

If you want to display the pathlines relative to the moving reference frame, enable the **Relative Pathlines** option in the Pathlines Dialog Box (p. 2771). You will then need to select the surfaces from the **Release from Surfaces** list.

31.1.4.2.11. Generating an XY Plot Along Pathline Trajectories

If you want to generate an XY plot along the trajectories of the pathlines you have defined, enable the **XY Plot** option in the Pathlines Dialog Box (p. 2771). The **Color by** drop-down list will be replaced by **Y Axis Function** and **X Axis Function** lists. Select the variable to be plotted on the y-axis in the **Y Axis Function** list, and specify whether you want to plot this quantity as a function of the **Time** elapsed along the trajectory, or the **Path Length** along the trajectory by selecting the appropriate item in the **X Axis Function** drop-down list. Specify the **Step Size**, number of **Steps**, and other parameters as usual for a standard pathline display. Then click **Plot** to display the XY plot.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once you have generated an XY plot, you may want to save the plot data to a file. You can read this file into ANSYS Fluent at a later time and plot it alone using the File XY Plot Dialog Box (p. 2599), as described in XY Plots of File Data (p. 1844), or add it to a plot of solution data, as described in Including External Data in the Solution XY Plot (p. 1844).

To save the plot data to a file, enable the **Write to File** option in the Pathlines Dialog Box (p. 2771). The **Plot** button changes to a **Write...** button. Clicking **Write...** opens The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the plot data. The format of this file is described in XY Plot File Format (p. 1850).

31.1.4.2.12. Saving Pathline Data

To save pathline data to a file, perform the following steps:

1. Enable the **Write to File** option in the Pathlines Dialog Box (p. 2771) (Figure 31.25: The Pathlines Dialog Box (p. 1773)).

2. In the **Type** drop-down list, select one of the following types of files:

   - **Standard** for `FIELDVIEW` (`.fvp`) format
   - **Geometry** for `.ibl` format (which can be read by GAMBIT)
   - **EnSight** format

   Important

   If you plan to write the pathline data in **EnSight** format, you should first verify that you have already written the files associated with the **EnSight Case Gold** file type by using the **File/Export...** ribbon tab option (see EnSight Case Gold Files (p. 76)).

   For further information about the files that are written for any of these types, refer to the appropriate section following these steps.

3. Choose to color the pathlines by any of the scalar fields in the **Color by** drop-down lists.

4. Select the surface(s) from which to release the particles in the **Release From Surfaces** list.

5. If you selected **EnSight** under **Type**, you will need to specify the **EnSight Encas File Name**. Use **Browse...** to select the `.encas` file that was created when you exported the file with the **File/Export...** ribbon tab option. If you do not make a selection, then you will need to create an appropriate `.encas` file manually.

   You can also select the number of **Time Steps For EnSight Export**. This number directly determines how many time levels will be available for animation in EnSight.

6. Click **Write...** to open The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the pathline data.

To initiate saving pathline data through the text command interface enter the following TUI command:

```
display/path-lines/write-to-files
```

In addition to pathline data, you can also export particle data in either **Standard**, **EnSight** or **Geometry** type. For information on exporting particle data in **FIELDVIEW** (standard), **EnSight** or `.ibl` (geometry) format, refer to Exporting Steady-State Particle History Data (p. 84).

31.1.4.2.12.1. Standard Type

If **Standard** is selected under **Type**, ANSYS Fluent will write the file in **FIELDVIEW** format, which can be exported and read into **FIELDVIEW**. The **FIELDVIEW** ASCII Particle Path Format is licensed from Intelligent Light, proprietor of an independent visualization software package (http://www.ilight.com). The file name that you use for saving the data must have a `.fvp` extension. You also have the ability to retrieve and display the particle and pathline trajectories from the file.

If the case is steady-state, the particle path information will be written in ASCII format. For transient or unsteady-state cases, the BINARY format must be used. The **FIELDVIEW** file contains a set of paths, where each path consists of a series of points. At every point the spatial location and selected variables are defined. A full description of the ASCII and BINARY formats can be found in Appendix K - Particle Path Formats of FIELDVIEW's Reference Manual [2] (p. 2887), available to licensed **FIELDVIEW** users.

The following is an example of the **FIELDVIEW** format for a steady-state case:

```
FVPARTICLES 2 1
Tag Names
0
Variable Names
2
time
particle_id
3
0.2 0.8 1.3 0.2 0
0.3 0.9 1.3 0.4 0
0.5 1.1 1.3 0.6 0
```

The beginning of the file displays header information. `Tag Names` cannot be specified when the file is exported from ANSYS Fluent, and hence will always be `0`. ANSYS Fluent enables you to export two variables, which are listed under `Variable Names`: the first is determined by the scalar fields selected in the **Color by** drop-down lists (`time` in the example above); the second is always `particle_id`.

The rest of the file contains information about each path. A path section begins by listing the total number of points for the path. Then a line of data is presented for each point, with the X, Y, and Z locations listed in the first three columns and the variable information in the fourth and fifth columns. The example above presents a single pathline consisting of three points; the time ranges from `.2` to `.6`, and the ID of the particle is `0`.

31.1.4.2.12.2. Geometry Type

If **Geometry** is selected under **Type**, the file will be written in `.ibl` format. The resulting file contains particle paths in the form of a curve that can be read in GAMBIT. The following is an example of a **Geometry** file format that contains multiple curves:

```
Closed Index Arclength
Begin section ! 1
 Begin curve ! 1
 1                  185.61      0                 23.26
   2       88.90000000000001      0                -89.67

   Begin curve ! 2
   1       88.89999999999569      0      -89.6699999999997
   2       76.90221619148909      0     -101.2290490001453
   3       62.92208239159677      0     -110.2907424975297
   4       47.47166726362848      0     -116.5231659809653
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
5       31.11689338997181      0     -119.6980363161113
6       14.45680848476821      0     -119.6990633707006
7      -1.898356710978934      0     -116.5262095254603
8      -17.34954014966171      0     -110.2956910520416
9      -31.33079110697006      0     -101.2357213074894
10       -43.330000000007      0     -89.67815166483965

Begin curve ! 3
1                  -43.33      0     -89.67815166485001
2                 -175.56      0         64.69066040289
```

The above example demonstrates how multiple curves can be imported; single curves may also be imported. After importing this file into GAMBIT, the file is read by first looking for a `Begin curve` string and then looking for the X, Y, and Z coordinates under the `Begin curve` line.

31.1.4.2.12.3. EnSight Type

By selecting **EnSight** under **Type**, you can generate files with the following extensions:

- `.mpg`
- `.mscl`
- `.encas`

An `.mpg` file will be written for every time step specified in the **Time Steps For EnSight Export** field. A sequential number will be appended to the `.mpg` extension to indicate the time step. Each file contains a header that lists the time at which the data was exported, as well as three columns listing the X, Y, and Z coordinates for every particle at that particular time step.

The following is an example of a file called `particle.mpg0003`, which contains data for nine particles at the third time step:

```
File is written from fluent in ensight measured particle format for
t = 2.42813e-04
particle coordinates
  9
  1-7.27734e-05 1.91710e-03 4.69093e-03
  2-1.75772e-04 1.97040e-03 3.92842e-03
  3-2.26051e-04 2.10134e-03 5.63228e-03
  4-1.16390e-04 2.32442e-03 5.23423e-03
  5-6.32735e-04 2.53326e-03 5.70791e-03
  6-9.69431e-04 2.37006e-03 5.27602e-03
  7-6.77868e-04 2.92054e-03 4.11570e-03
  8-9.78029e-04 2.75717e-03 4.13314e-03
  9-8.54859e-04 3.73727e-03 2.23796e-03
```

An `.mscl` file will be written for every time step specified in the **Time Steps For EnSight Export** field. A sequential number will be appended to the `.mscl` extension to indicate the time step. Each file contains the scalar information (specified under **Color By**) for every particle at a particular time step.

The following is an example of a file called `particle.mscl0006`, which captures **Particle ID** data for nine particles at the sixth time step:

```
particle id
 0.00000e+00 6.00000e+00 1.20000e+01 1.80000e+01 2.40000e+01 3.00000e+01
 3.60000e+01 4.20000e+01 4.80000e+01
```

A new `.encas` file will be written if a selection is made under **EnSight Encas File Name**. This new file is a modified version of the `.encas` file selected with the **Browse...** button, and contains information about all of the related files (including geometry, velocity, scalar and coordinate files). The name of the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

new file will be the root of the original file with `.new` appended to it (for example if `test.encas` is selected, a file named `test.new.encas` will be written). It is this new file that should be read into **EnSight**.

The following is an example of a file called `spray2-unsteady.new.encas`, that refers to the files generated when the data was originally exported as an **EnSight Case Gold** file type (`.geo`, `.vel`, `.sc11`, and `.sc12`) and the files created during the pathline data export (`.mpg` and `.mscl`):

```
FORMAT
type: ensight gold
GEOMETRY
model: spray2-unsteady.geo
measured: 1 particle.mpg****
VARIABLE
scalar per measured node: 1 particle-id particle.mscl****
scalar per node: pressure                     spray2-unsteady.scl1
scalar per node: pressure-coefficient         spray2-unsteady.scl2
vector per node: velocity                     spray2-unsteady.vel
TIME
time set: 1 Model
number of steps: 10
filename start number:   1
filename increment:      1
time values: 0.00000e+00 1.21406e-04 2.42813e-04 3.64219e-04 4.85626e-04
6.07032e-04 7.28438e-04 8.49845e-04 9.71251e-04 1.09266e-03
```

31.1.4.2.13. Choosing Node or Cell Values

In ANSYS Fluent you can determine the scalar field value at a particle location using the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are used. If you prefer to use the cell values, turn the **Node Values** option off. Note that for face-only functions like **Wall Shear Stress**, the cell value is the area-weighted average from the face values that define that cell as `c0`.

If you are plotting pathlines to show the effect of a porous medium or 2D fan boundary, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

31.1.4.3. Creating and Using Pathline Definitions

You can create named pathline definitions and save them for later use. See Creating and Using Contour Plot Definitions (p. 1762) for additional information on graphics object definitions.

The steps for creating and using pathline definitions are similar to the Steps for Generating Pathlines (p. 1772), with the addition of a field for naming the pathline definition.

Pathline definitions can be included in scenes as long as the **XY Plot** option is not enabled.

31.1.5. Displaying a Scene

Scenes can be used to display multiple graphics plots within a single window. For example, you could overlay contours of pressure across a valve with velocity vectors and the mesh at the same location. Scenes allow you to modify the transparency of each plot so that you can emphasize a particular plot or view.

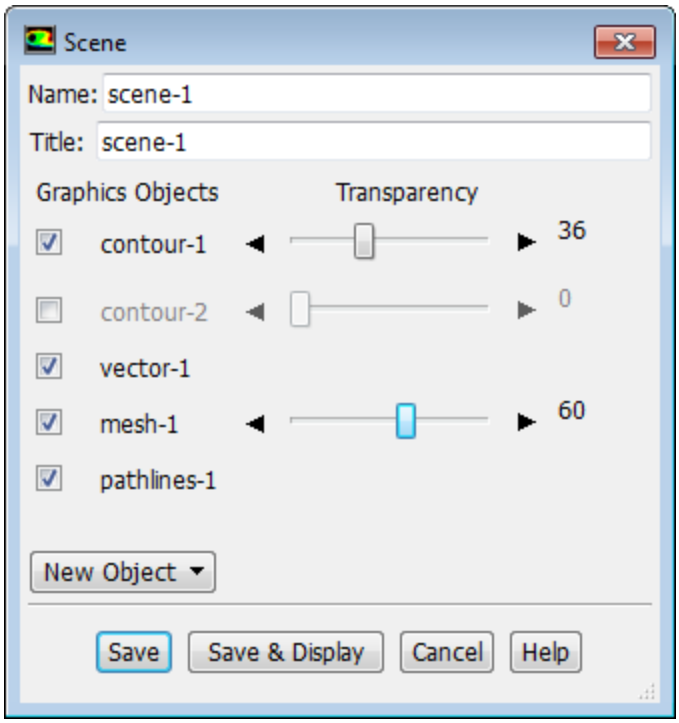
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.1.5.1. Generating a Scene

You can plot a scene made up of multiple graphics objects using the Figure 31.26: The Scene Dialog Box (p. 1781).

Results → Scene New...

Figure 31.26: The Scene Dialog Box



The basic steps for creating a scene:

1. (Optional) Enter a **Name** for the scene.
2. (Optional) Enter a **Title** for the scene, which will appear in the graphics window tab where the scene is displayed.
3. Select the **Graphics Objects** that you want to include in the scene. *If you want to include additional mesh, contour, vector, or pathline plots in the scene, create them from the **New Object** drop-down list.*

   *Note that pathlines with the **XY Plot** option enabled are not compatible with scenes.*
4. (Optional) You can modify the transparency of the selected graphics objects using the **Transparency** slider. *If the slider is completely to the right the object will be fully transparent.*
5. Click **Save** or **Save & Display**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scene Colormaps

Once the scene is displayed, you can move the colormaps by left-click and drag. Colormaps can also be resized by dragging the corners of the box that appears when you hover over the colormap.

Tip

You can specify a different colormap scale for each graphic object to make it easier to determine the values that correspond to the displayed gradients (to do this, click **Colormap Options...** in the corresponding graphics object dialog box).

31.1.6. Displaying Results on a Sweep Surface

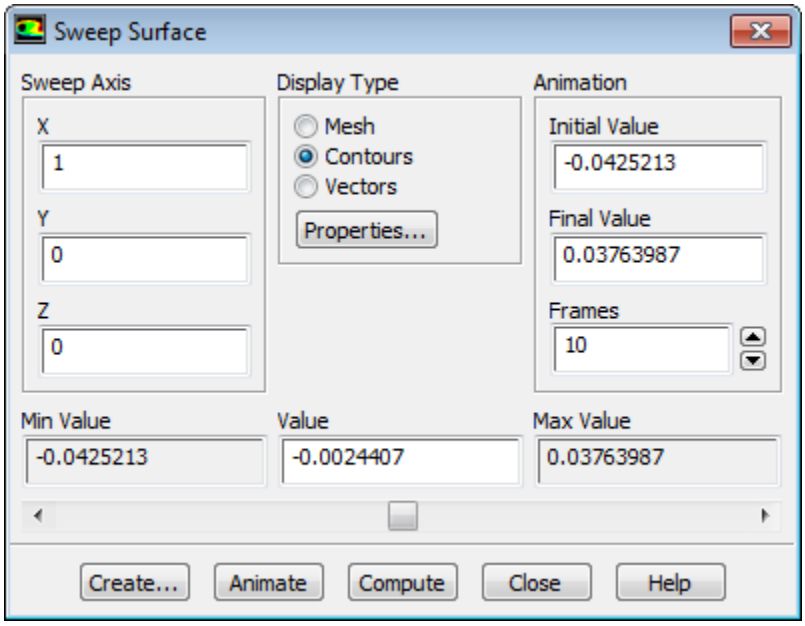
Sweep surfaces can be used when you want to examine the mesh, contours, or vectors on various sections of the domain without explicitly creating the corresponding surfaces. For example, if you want to display solution results for a 3D combustion chamber, instead of creating numerous surfaces at different cross-sections of the domain, you can use a sweep surface to view the variation of the flow and temperature throughout the chamber.

31.1.6.1. Steps for Generating a Plot Using a Sweep Surface

You can plot meshes, contours, or vectors on a sweep surface using the Sweep Surface Dialog Box (p. 2565) (Figure 31.27: The Sweep Surface Dialog Box (p. 1782)).

Results → Animations → Sweep Surface Edit...

Figure 31.27: The Sweep Surface Dialog Box



The basic steps for generating a mesh, contour, or vector plot using a sweep surface are as follows:

1. Under **Sweep Axis**, specify the (**X**, **Y**, **Z**) vector representing the axis along which the surface should be swept.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Compute** to update the **Min Value** and **Max Value** to reflect the extents of the domain along the specified axis.

3. Under **Display Type**, specify the type of display you want to see: **Mesh**, **Contours**, or **Vectors**. The first time that you select **Contours** or **Vectors**, ANSYS Fluent will open the Contours Dialog Box (p. 2676) or the Vectors Dialog Box (p. 2831) so you can modify the settings for the display. To make subsequent modifications to the display settings, click **Properties** to open the Contours Dialog Box (p. 2676) or Vectors Dialog Box (p. 2831).

4. Move the slider under **Value** (which indicates the value of *x*, *y*, or *z*) to move the sweep surface through the domain along the specified **Sweep Axis**. ANSYS Fluent will update the mesh, contour, or vector display when you release the slider. You can also enter a position in the **Value** field and press **Enter** to update the display.

5. If you want to save the currently displayed sweep surface so that you can use it for a different type of plot (for example, a pathlines plot or an XY plot) or combine it with displays on other surfaces, click **Create...** to open the Create Surface Dialog Box (p. 2566) (Figure 31.28: The Create Surface Dialog Box (p. 1783)). Enter the **Surface Name** and click **OK**.

   Figure 31.28: The Create Surface Dialog Box

   
   The surface that is created is an isosurface based on the mesh coordinates; the contour or vector settings are not stored in the surface.

You can also animate the sweep surface display, as described below, rather than moving the slide bar yourself.

31.1.6.2. Animating a Sweep Surface Display

The steps for animating a sweep surface display are as follows:

1. Specify the **Sweep Axis** and **Display Type** as described above.

2. Under **Animation**, enter the **Initial Value** and **Final Value** for the animation. These values correspond to the minimum and maximum values along the **Sweep Axis** for which you want to animate the display.

3. Specify the number of **Frames** you want to see in the animation.

4. Click **Animate**.

31.1.7. Hiding the Graphics Window Display

There may be situations where displaying graphics on a local machine is not practical. Therefore, you may decide to hide (or disable) the graphics display window.

To disable the graphics display window when starting ANSYS Fluent from the command line, you can specify the driver as null:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
fluent -driver null
```

For an ANSYS Fluent session that is already in progress, the graphics window display can be disabled using the following TUI command:

`display → set → rendering-options → driver → null`

Important

All graphics windows must be closed prior to invoking the above TUI command.

If the graphics window display is disabled, you can continue to save graphics using the **Save Picture** option, as described in Saving Picture Files (p. 102). The saved graphics files will be identical whether the graphics window display is enabled or disabled.

For an ANSYS Fluent session that is already in progress, to re-enable a graphics window display that had been previously disabled, use the following TUI command:

`display → set → rendering-options → driver → opengl`

If any graphics windows are open (which are not visible to you), ANSYS Fluent will prompt you to close all open windows. You can close them using the following Scheme command:

```
(close-all-open-windows)
```

and then retype the TUI command to enable the graphics windows.

Important

If you happen to be logged on to a machine remotely, then `opengl` may not work on your system. Use `x11` instead to enable your graphics windows.

31.2. Customizing the Graphics Display

There are a number of ways in which you can alter the graphical display once you have generated the basic elements in it (contours, meshes, and so on). For example, you can overlay multiple graphics, add descriptive text or lighting to the plot, and modify the captions or legend layout. These and other customizations are described in this section.

31.2.1. Advanced Graphics Overlays
31.2.2. Opening Multiple Graphics Windows
31.2.3. Changing the Legend Display
31.2.4. Adding Text to the Graphics Window
31.2.5. Changing the Colormap
31.2.6. Adding Lights
31.2.7. Modifying the Rendering Options

Important

It is possible that the graphics window may become **[Out of Date]** (which would be indicated at the top of the graphics window), if you make changes to items that are already displayed. To resolve this out of date state, right-click in the graphics window and click **Refresh Display** in the context menu that appears.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

*If a context menu does not appear on a right-click of the graphics window, ensure that the right-mouse button is set to an action other than **mouse-zoom** or **mouse-probe** and **long description** (**Viewing** ribbon tab, **Mouse** group box).*

31.2.1. Advanced Graphics Overlays

Normally, you can see only one picture at a time in the graphics window, unless you are Displaying a Scene (p. 1780). Sometimes, however, you may want to create an "exploded" view, where results translated or rotated out for the physical domain for enhanced display (see Figure 31.29: Exploded Scene Display of Temperature and Velocity (p. 1786)). You can do this by turning on the **Overlays** option (and clicking **Apply**) and using the transform operation in the Scene Description Dialog Box (p. 2577).

Viewing → Graphics → Compose...

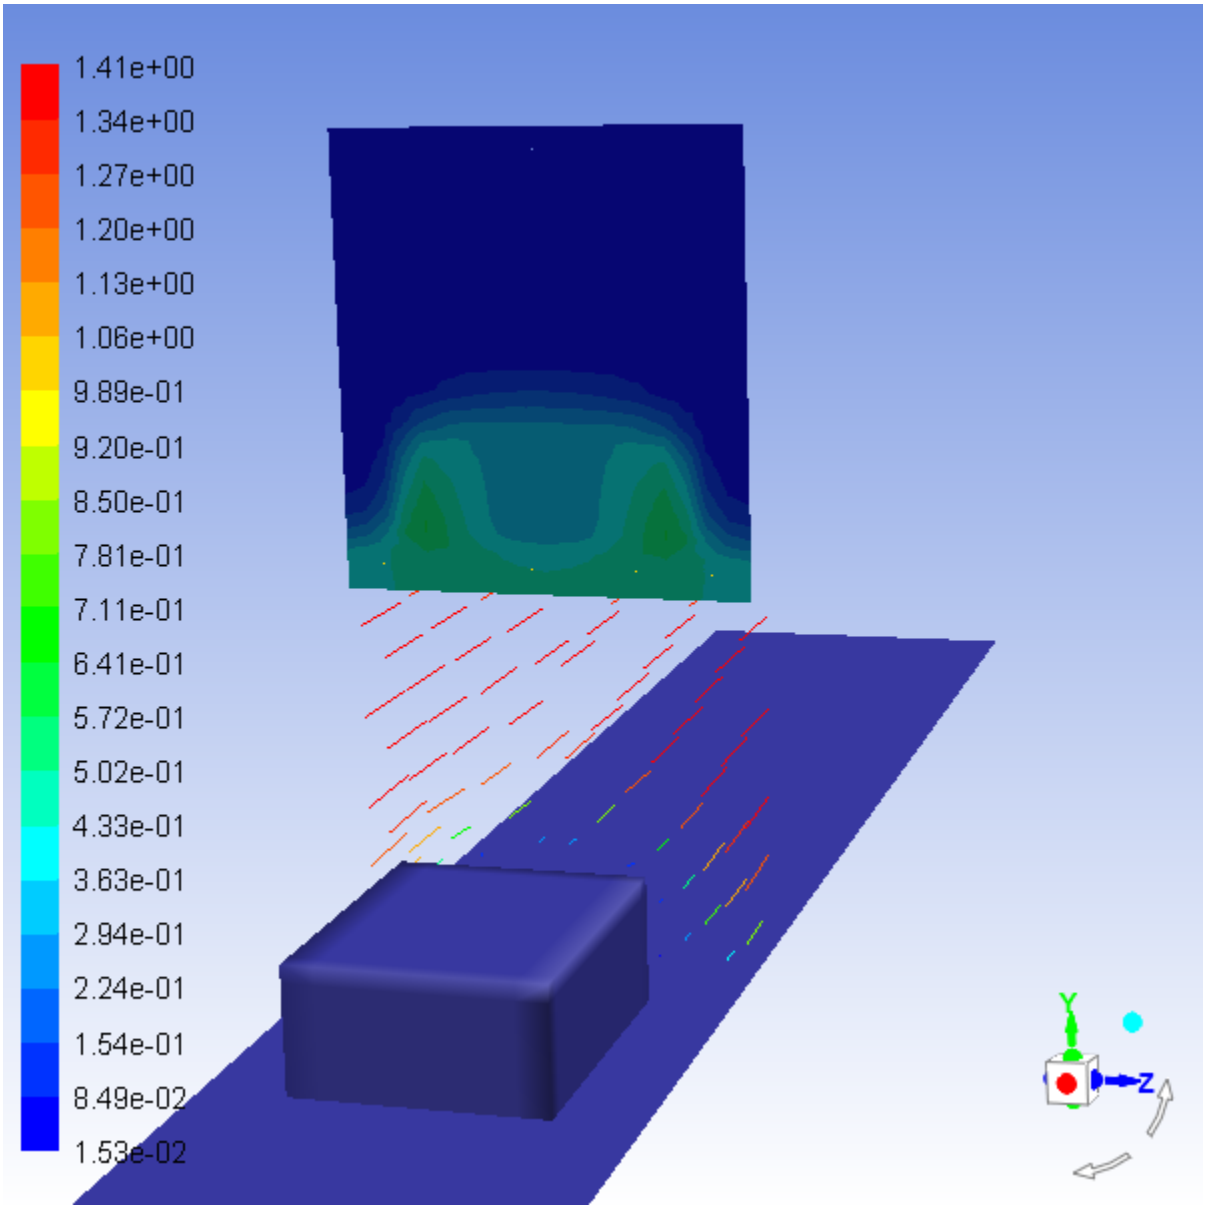
Once overlaying is enabled, subsequent graphics that you generate will be displayed on top of the existing display in the active graphics window. To generate a plot without overlays, you must turn off the **Overlays** option in the Scene Description Dialog Box (p. 2577) (and remember to click **Apply**).

When you are overlaying multiple graphics, the captions and color scale that will appear in the latest display are those that correspond to the most recently drawn graphic.

Note that when overlaying is enabled, it will apply to all graphics windows, including those that are not yet open. Turning overlays on and off does so for all graphics windows, not just for the active window. That is, if you enable overlays, open a new graphics window (as described in Opening Multiple Graphics Windows (p. 1786)), and then generate two or more graphics in that window, they will be overlaid.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.29: Exploded Scene Display of Temperature and Velocity



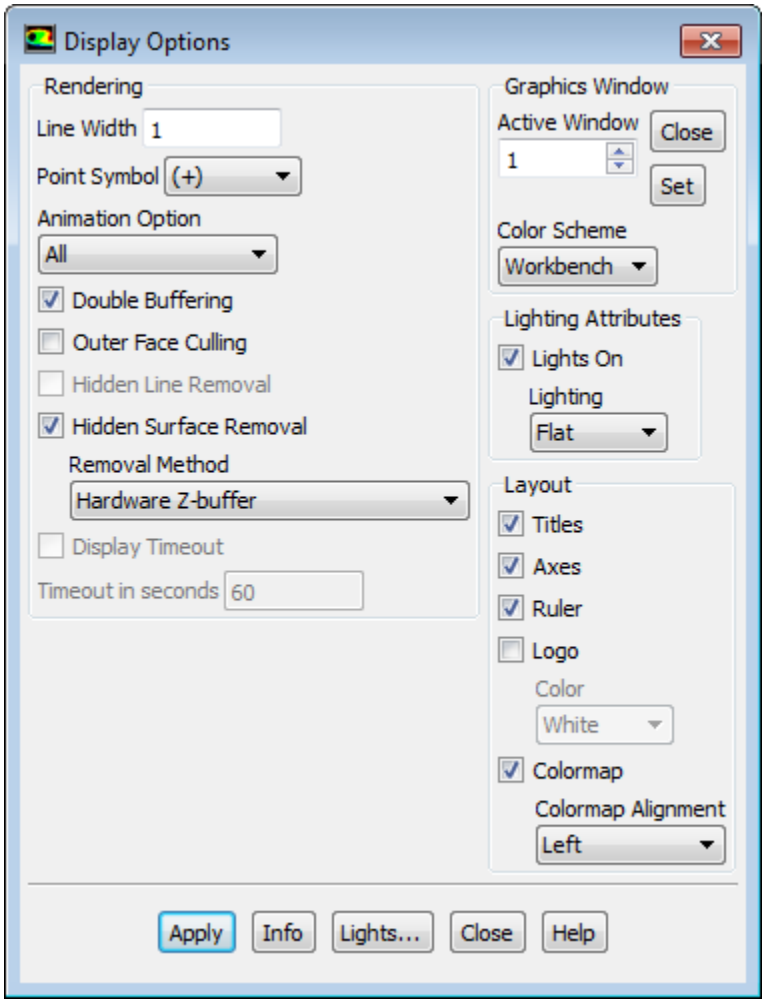
31.2.2. Opening Multiple Graphics Windows

During your ANSYS Fluent session, you can open up to 20 graphics windows at one time and they may be viewed within the application window or in separate windows. The windows are numbered 1 through 20 and the ID number for each window will appear at the top of the frame that surrounds it. You can view a specific window by selecting it from the drop-down list next to the ID number. The first time you display graphics, window 1 will be displayed automatically. To open an additional window, you can use the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

Results → Graphics Options...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.30: The Display Options Dialog Box



Use the up arrow to increment the window ID in the **Active Window** field under **Graphics Window** and then click **Open**. The **Close** button changes to the **Open** button if the **Active Window** is set to more than **1**.

To close an open window, increase or decrease the **Active Window** value to the ID of the window to be closed, and then click **Close** that appears next to the **Active Window** field. The **Open** button changes to a **Close** button if the **Active Window** is open.

To display a different color scheme for the graphics window, select **Classic** or **Workbench** from the drop-down list located below the **Active Window** field. All graphics windows will change.

31.2.2.1. Setting the Active Window

When you have more than one graphics window open, you must identify the active window so that ANSYS Fluent will know which one to draw the plot in. There are two ways to set the active window: you can simply click any mouse button in the desired graphics window, or you can specify the ID for the desired graphics window in the **Active Window** field (in the Display Options Dialog Box (p. 2573)) and click **Set**. Regardless of the method used, this window will remain active until you set a new active window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.2.3. Changing the Legend Display

ANSYS Fluent graphics include, by default, a caption or legend block that consists of fields of text describing the contents of the graphic, the ANSYS Fluent product identification, an axis triad indicating the orientation of the displayed object, a color key defining the correspondence between each color and the magnitude of the plotted variable, and the ANSYS logo. You can turn off the display of the legend and color scale, and/or the axis triad. You can also hide the ANSYS logo. You can also display the colormap on any side of the display window as per convenience. In addition you can also edit the captions directly in the graphics window.

31.2.3.1. Enabling/Disabling the Legend, Logo, and Color Scale

You can disable the display of the **Titles**, **Axes**, **Logo**, and the **Colormap** scale by deselecting each of the options under **Layout** in the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

Results → Graphics Options...

Use the text interface to enable/disable the captions and color scale individually, and to change the size and position of the captions and color scale.

`display → set → windows → text →`

`display → set → windows → scale →`

See the separate Text Command List for details.

31.2.3.2. Editing the Legend

When captions are displayed in the graphics window, you may choose to modify, delete, or add to the text that appears in the caption box. To do so, click the left mouse button in the desired location. A cursor will appear, and you can then type new text or delete the text that was originally there (using the backspace or delete key). Note that changes to existing text in the caption block will be removed when you draw new graphics in the window (unless you are overlaying multiple graphics in the same window), but text that you add on a previously empty line in the caption block will not be removed until the default caption text makes use of that line.

31.2.3.3. Adding a Title to the Caption

You can define a title for your problem using the `title` text command:

`display → set → title`

The title you define will appear on the top line of the caption, at the far left, in all subsequent plots. It will also be saved in the case file.

Important

You will need to enclose your title in quotation marks (for example, " `my title` ").

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.2.3.4. Enabling/Disabling the Axes

You can disable the display of the axis triad by turning off the **Axes** option under **Layout** in the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

31.2.3.5. Enabling/Disabling the Ruler

You can disable the display of the ruler by turning off the **Ruler** option under **Layout** in the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

Note that if your project is 3D, then you must be in orthographic view in order to use the ruler.

31.2.3.6. Modifying and Displaying/Hiding the Logo

The graphics window displays a white ANSYS logo in the upper right corner. You may choose between a white (default) or black logo by selecting **White** or **Black** from the **Color** drop-down list under **Layout** in the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

You can prevent the ANSYS logo from being displayed in the graphics window by disabling the **Logo** option under **Layout**.

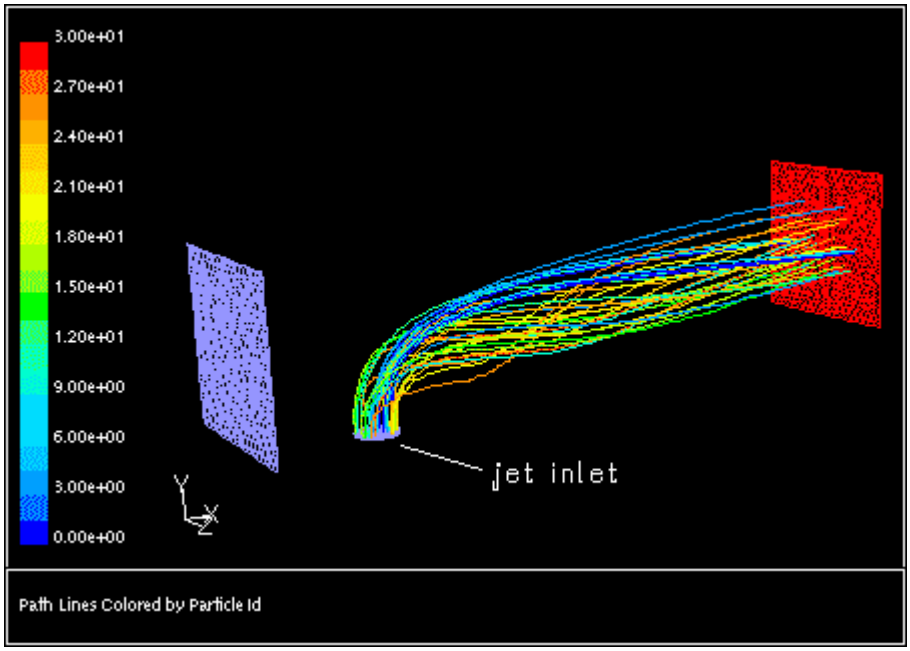
31.2.3.7. Colormap Alignment

You can set the position of the colormap on any side (left, top, bottom, or right) of the display window. Default alignment for the colormap is set to the **Left**. If you want to change the alignment, select the required direction in the **Colormap Alignment** drop-down list.

31.2.4. Adding Text to the Graphics Window

You can use the Annotate Dialog Box (p. 2592) to add text to the graphics window with optional attachment lines. Figure 31.31: Graphics Window with Text Annotation (p. 1789) shows an example of a graphics display with annotated text in it.

Figure 31.31: Graphics Window with Text Annotation

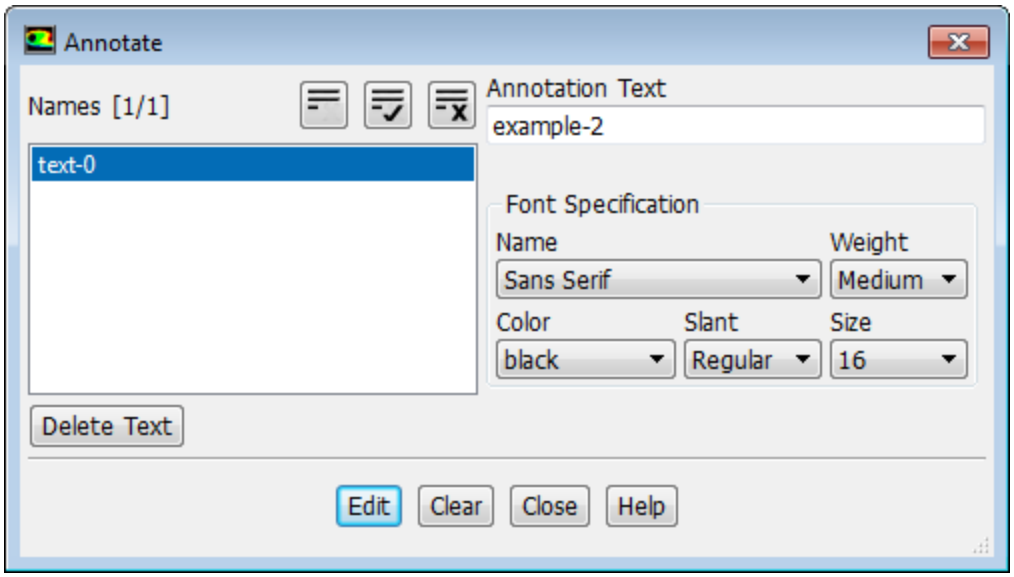


31.2.4.1. Adding Text Using the Annotate Dialog Box

Adding text to the graphics window using the Annotate Dialog Box (p. 2592) (Figure 31.32: The Annotate Dialog Box (p. 1790)) enables you to control the font and color of the text.

Results → Graphics Annotate...

Figure 31.32: The Annotate Dialog Box



The steps for adding text are as follows:

1. Under **Font Specification**, select the font type in the **Name** drop-down list, the font weight (**Medium** or **Bold**) in the **Weight** drop-down list, the size (in points) in the **Size** drop-down list, the color in the **Color** drop-down list, and the slant (**Regular** or **Italic**) in the **Slant** drop-down list.

2. Enter the text that you want to add in the **Annotation Text** field.

3. Click **Add**. You will be asked to pick the location in the graphics window where you want to place the text, using the mouse-probe button. By default, the mouse-probe button is the right button, but you can change this in the **Mouse** group box of the **Viewing** tab, as described in Controlling the Mouse Button Functions (p. 1800).

   If you click the mouse button once in the desired location, the text will be placed at that point. Dragging the mouse with the mouse-probe button depressed will draw an attachment line from the point where the mouse was first clicked to the point where it was released. The annotation text will be placed at the point where the mouse button was released.

31.2.4.2. Editing Existing Annotation Text

Once you have added text to the graphics display, you may change the font characteristics of one or more text items, or delete individual text items.

To modify or delete existing text, follow these steps:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the appropriate item in the **Names** list in the Annotate Dialog Box (p. 2592) (Figure 31.32: The Annotate Dialog Box (p. 1790)). When you select a name, the associated text will be displayed in the **Annotation Text** field, and the **Add** button becomes the **Edit** button.

2. Modify the **Font Specification** entries as desired, and click **Edit** to modify the text, or simply click **Delete Text** below the **Names** list to delete the selected text.

Note that if you want to make changes to all current annotation text, you can select all of the **Names** instead of just one in step 1.

You can move the text in the same way that you move other geometric objects in the display, using the Scene Description Dialog Box (p. 2577) and the Transformations Dialog Box (p. 2580). See Transforming Geometric Objects in a Scene (p. 1819) for details.

31.2.4.3. Clearing Annotation Text

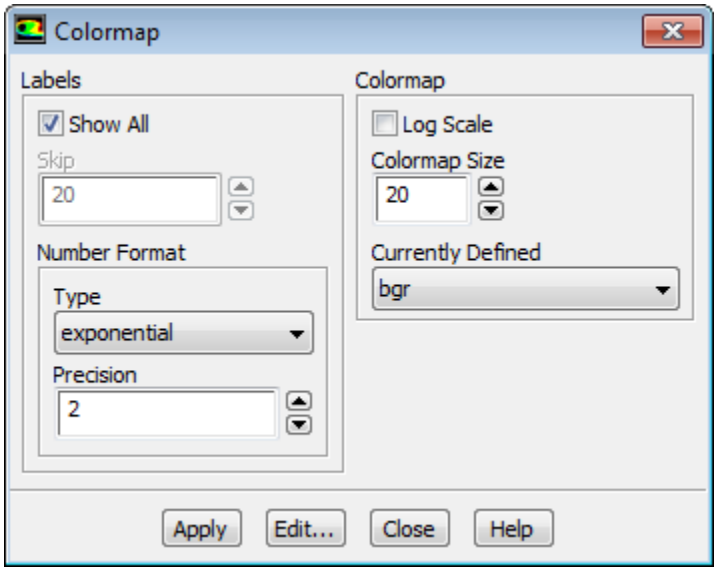
Annotation text is associated with the active graphics window and is removed only when the annotations are explicitly cleared. To remove the annotations from the graphics window, you must click **Clear** in the Annotate Dialog Box (p. 2592). If you draw new graphics in the window without clearing the annotations, they will remain visible in the new display.

31.2.5. Changing the Colormap

The default colormap used by ANSYS Fluent to display graphical data (for example, vectors) ranges from blue (minimum value) to red (maximum value). Additional predefined colormaps are available, and you can also create custom colormaps. To make any changes to the colormap, you will use the Colormap Dialog Box (p. 2589) (Figure 31.33: The Colormap Dialog Box (p. 1791)).

Results → Graphics Colormap...

Figure 31.33: The Colormap Dialog Box



When you plot contours, you can temporarily modify the number of colors in the colormap by changing the number of contour levels in the Contours Dialog Box (p. 2676); you will only need to use the Colormap Dialog Box (p. 2589) if you want to change other characteristics of the colormap.

Important

Note that if you are using a gray-scale colormap and you want to save a gray-scale picture, you should save a color picture. When you save a gray-scale picture, ANSYS Fluent uses an internal gray scale, not the gray scale specified by the colormap. If you save a color picture, the colormap you selected (that is, your gray scale) will be used.

31.2.5.1. Predefined Colormaps

The following colormaps are automatically available in ANSYS Fluent:

bgr:
Blue represents the minimum value, green the middle, and red the maximum value. Colors in between are interpolated from blue to green, and from green to red. (This is the default colormap.)

bgrb:
Blue represents the minimum and maximum values, and green and red are values 1/3 and 2/3 of the maximum value, respectively. Colors in between are interpolated from blue to green, from green to red, and from red to blue.

blue:
The minimum value is represented by blue-black, and the maximum value by pure blue.

cyan-yellow:
Cyan represents the minimum value and yellow represents the maximum value.

fea:
Blue represents the minimum value and red represents the maximum value. The colors in between are those used in third-party finite element analysis packages.

gray:
Black is used for the minimum value and white for the maximum value.

green:
The minimum value is represented by green-black, and the maximum value by pure green.

purple-magenta:
Purple represents the minimum value and magenta represents the maximum value.

red:
The minimum value is represented by red-black, and the maximum value by pure red.

rgb:
Red represents the minimum value, green the middle, and blue the maximum value. Colors in between are interpolated from red to green, and from green to blue.

The number of colors interpolated between the colors in the scale name (for example, between purple and magenta) will depend on the size of the colormap.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.2.5.2. Selecting a Colormap

The procedure for selecting a new colormap to be used in graphics displays is as follows:

1. In the Colormap Dialog Box (p. 2589) (Figure 31.33: The Colormap Dialog Box (p. 1791)), select the desired colormap in the **Currently Defined** drop-down list. This list will contain all of the colormaps predefined by ANSYS Fluent as well as any custom colormaps that you have created as described in Creating a Customized Colormap (p. 1795).

2. Set the colormap size and scale as described in Specifying the Colormap Size and Scale (p. 1793).

3. Click **Apply** to update the current graphics display with the new colormap. All future displays will use the newly selected colormap and options.

31.2.5.2.1. Specifying the Colormap Size and Scale

Once you have selected the desired colormap from the **Currently Defined** list, you may modify the **Colormap Size**. This value is the number of distinct colors in the color scale.

You can also choose to use a logarithmic scale instead of a decimal scale by turning on the **Log Scale** option. With a log scale, the color used in the graphics display will represent the log of the value at that location in the domain. The values represented by the colors will, therefore, increase exponentially.

31.2.5.2.2. Changing the Number Format

You can change the format of the labels that define the color divisions at the left of the graphics window using the controls under the **Number Format** heading in the Colormap Dialog Box (p. 2589).

- To display the real value with an integral and fractional part (for example, 1.0000), select **float** in the **Type** drop-down list. You can set the number of digits in the fractional part by changing the value of **Precision**.

- To display the real value with a mantissa and exponent (for example, 1.0e-02), select **exponential** in the **Type** drop-down list. You can define the number of digits in the fractional part of the mantissa in the **Precision** field.

- To display the real value with either float or exponential form, depending on the size of the number and the defined **Precision**, choose **general** in the **Type** drop-down list.

31.2.5.3. Displaying Colormap Label

You can customize the number of values displayed on the colormap. The default number of labels that appear alongside the colormap depends on the font size and the colormap size (Figure 31.34: The Default Colormap Label Display (p. 1794)).

- To reduce the number of labels that appear alongside the colormap, increase the number of labels skipped. To do so, deselect **Show All** in the Colormap Dialog Box (p. 2589) and set the number of labels to be skipped.

  To demonstrate what effect this command has on the display, enter a value of 4 under **Skip** (note that the value entered must be an integer). This will result in three intermediate labels being skipped, with the first and the last colormap values always being displayed (Figure 31.35: The Colormap with Skipped Labels (p. 1794)).

- To reset the original colormap display, simply select **Show All**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.34: The Default Colormap Label Display

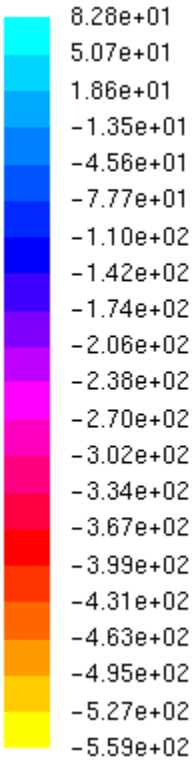


Figure 31.35: The Colormap with Skipped Labels

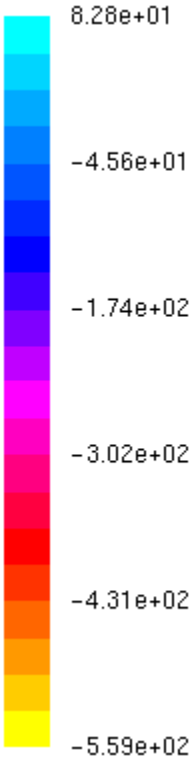


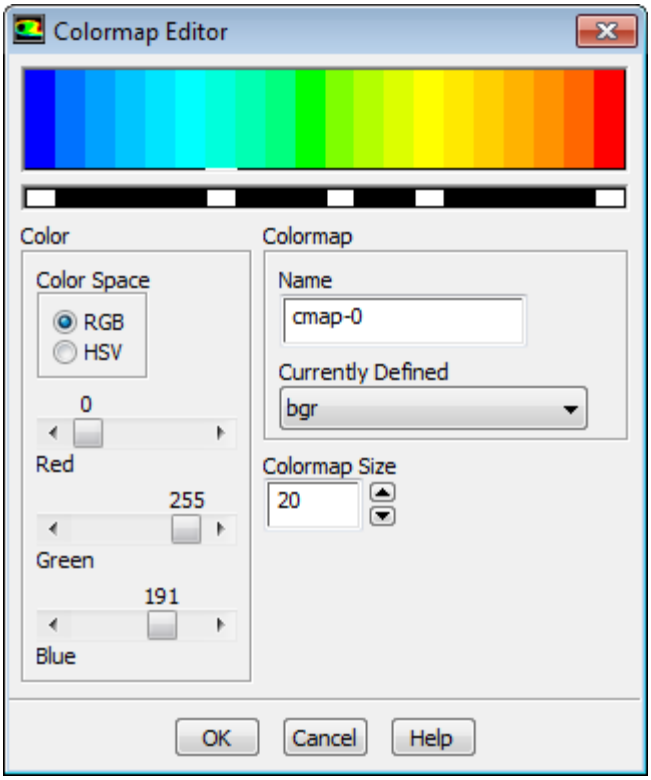
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

31.2.5.4. Creating a Customized Colormap

You can create your own colormap by manipulating the "anchor colors" and the colormap size. A color scale is created by linear interpolation between the anchor colors. The color, number, and position of the anchor colors will therefore control the description of the colormap. By increasing the colormap size, you can increase the total number of colors and obtain a color scale that changes more gradually. The procedure is as follows:

1. In the Colormap Dialog Box (p. 2589), click **Edit...** to open the Colormap Editor Dialog Box (p. 2591) (Figure 31.36: The Colormap Editor Dialog Box (p. 1795)).

   Figure 31.36: The Colormap Editor Dialog Box



2. In the Colormap Editor Dialog Box (p. 2591), select a color scale in the **Currently Defined** list as your starting point. The colors in the scale will be displayed at the top of the dialog box. A white bar below a color is an "anchor point" indicating that this color is an "anchor color".

3. If you want to add more colors to the color scale, increase the **Colormap Size**; to use fewer colors, decrease this value. When you use the counter arrows (or type in a value and press **Enter**), the color scale display at the top of the dialog box will be updated immediately.

   Important

   The total number of colors must not be less than the number of anchor points.

4. To obtain the desired color scale interpolation, manipulate the anchor colors as needed:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To add an anchor point, click any mouse button on the black space directly below the desired anchor color (or click the color itself). A white bar will appear below the color to identify it as an anchor color, and the color will automatically be selected for color-definition modification.
- To remove an anchor point, click the white bar below the anchor color. The white bar will disappear and the color scale will be updated to reflect the new interpolation.
- To select a current anchor color in order to modify its color definition, click the color itself at the top of the dialog box.
- To modify the color of the selected anchor color, you can change either the red/green/blue components (choose **RGB**, the default) or the hue/saturation/value components (choose **HSV**). **HSV** is recommended if you plan to record the graphics display on video, as it enables you to create a more subtle gradation of color and reduce the tendency of bright colors to "bleed". Move the **Red**, **Green**, and **Blue** or **Hue**, **Saturation**, and **Value** sliders to obtain the desired color. The color scale at the top of the dialog box will be updated automatically to show the effect of your change.

  Important

  It is a good idea to note the original value of a color component before moving the slider so that you will be able to return to it if you change your mind. (See Scales (p. 17) for instructions on using a scale slider.)

  If you make a mistake while modifying the color scale, you can start over by selecting the starting-point colormap in the **Currently Defined** list.

5. If you want to change the default name of the new colormap, enter the new name in the **Name** field. By default, custom colormaps are called `cmap-0`, `cmap-1`, and so on.
6. Click **OK** to save the new colormap. The colormap name appears in the **Currently Defined** list in the Colormap Dialog Box (p. 2589) and can be selected for use in the graphics display.

Custom colormap definitions will be saved in the case file.

31.2.6. Adding Lights

In ANSYS Fluent you can add lights with a specified color and direction to your display. These lights can enhance the appearance of the display when it contains 3D geometries. By default one light is defined. You can enable the effect of the existing light(s) using the Display Options Dialog Box (p. 2573) or the Lights Dialog Box (p. 2588), and you can add new lights using the Lights Dialog Box (p. 2588).

31.2.6.1. Turning on Lighting Effects with the Display Options Dialog Box

To enable the effect of lighting, you can use the Display Options Dialog Box (p. 2573).

Results → Graphics Options...

If you enable the **Lights On** option under **Lighting Attributes** and click **Apply**, you will see the lighting effects in the active graphics window. To turn off the lighting effects, simply turn off the **Lights On** option and click **Apply**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also choose the method to be used in lighting interpolation; select **Flat**, **Gouraud**, or **Phong** in the **Lighting** drop-down list. Flat is the most basic method: there is no interpolation within the individual polygonal facets. Gouraud and Phong have smoother gradations of color because they interpolate on each facet.

31.2.6.2. Turning on Lighting Effects with the Lights Dialog Box

You can also enable lighting effects using the Lights Dialog Box (p. 2588) (Figure 31.37: The Lights Dialog Box (p. 1797)).

Results → Graphics Lights...

For constant lighting effects in the direction of the view, enable the **Headlight On** option in the Lights Dialog Box (p. 2588). This option has the effect of a light source directly in front of the model, no matter what orientation the model is viewed in. To disable this feature, turn off the **Headlight On** option in the Lights Dialog Box (p. 2588).

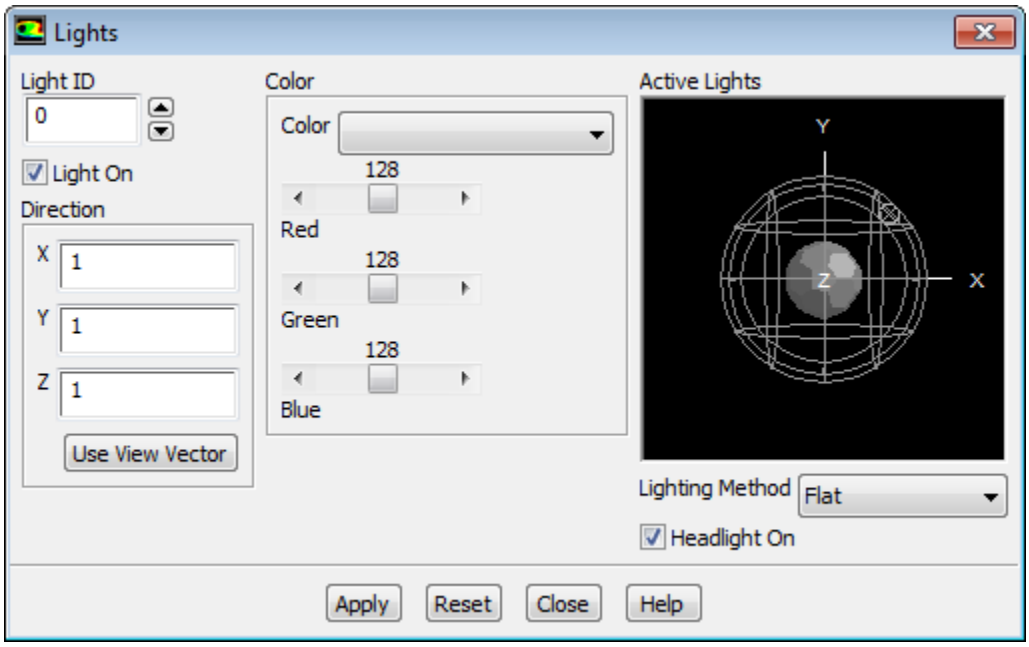
In the **Lighting Method** drop-down list, choose **Flat**, **Gouraud**, or **Phong** to enable the appropriate lighting method. These methods are described in the previous section. To disable lighting, select **Off** in the list. To see the lighting effects in the active graphics window, click **Apply**.

31.2.6.3. Defining Light Sources

You can control individual lights in the Lights Dialog Box (p. 2588) (Figure 31.37: The Lights Dialog Box (p. 1797)). The Lights Dialog Box (p. 2588) enables you to create a light and then turn it off without deleting it. In this way, you can retain lights that you have defined previously but do not want to use at present.

Results → Graphics Lights...

Figure 31.37: The Lights Dialog Box



(You can also open the Lights Dialog Box (p. 2588) by clicking **Lights...** in the Display Options Dialog Box (p. 2573).)

By default, light 0 is defined to be dark gray with a direction of (1,1,1). A light source is a distant light, similar to the sun. The direction (1,1,1) means that the rays from the light will be parallel to the vector from (1,1,1) to the origin. To create an additional light (for example, light 1), follow the steps listed below.

1. Increase **Light ID** to a new value (for example, 1).
2. Enable the **Light On** check box.
3. Define the light color by entering a descriptive string (for example, `lavender`) in the **Color** field, or by moving the **Red**, **Green**, and **Blue** sliders to obtain the desired color. The default color for all lights is dark gray.
4. Specify the light direction by doing one of the following:
   - Enter the (**X**, **Y**, **Z**) Cartesian components under **Direction**.
   - Click the middle mouse button in the desired location on the sphere under **Active Lights**. (You can also move the light along the circles on the surface of the sphere by dragging the mouse while holding down the middle button.) You can rotate the sphere by pressing the left mouse button and moving the mouse (like a trackball).
   - Use your mouse to change the view in the graphics window so that your position in reference to the geometry is the position from which you would like a light to shine. Then click **Use View Vector** to update the **X,Y,Z** fields with the appropriate values for your current position and update the graphics display with the new light direction. This method is convenient if you know where you want a light to be, but you are not sure of the exact direction vector.
5. Repeat steps 1–4 to add more lights.
6. When you have defined all the lights you want, click **Apply** to save their definitions.

31.2.6.3.1. Removing a Light

To remove a light, enter the ID number of the light to be removed in the **Light ID** field and then clear the **Light On** check box. When a light is turned off, its definition is retained, so you can easily add it to the display again at a later time by selecting the **Light On** check box. For example, you may want to define three different lights to be used in different scenes. You can define each of them, and then enable only one or two at a time, using the **Light ID** field and the **Light On** check box. Once you have made all the desired modifications to the lights, remember to click **Apply** to save the changes.

31.2.6.3.2. Resetting the Light Definitions

If you have made changes to the light definitions, but you have not yet clicked **Apply**, you can reset the lights by clicking **Reset**. All lighting characteristics will revert to the last saved state (that is, the lighting that was in effect the last time you opened the dialog box or clicked on **Apply**).

31.2.7. Modifying the Rendering Options

Depending on the objects in your display window and what kind of graphics hardware and software you are using, you may want to modify some of the rendering parameters listed below. All are listed

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

under the **Rendering** heading in the Display Options Dialog Box (p. 2573) (Figure 31.30: The Display Options Dialog Box (p. 1787)).

Results → Graphics Options...

After making a change to any of these rendering parameters, click **Apply** to re-render the scene in the active graphics window with the new attributes. To see the effect of the new attributes on another graphics window, you must redisplay it or make it the active window (see Setting the Active Window (p. 1787)) and click **Apply** again.

Line Width:

By default, all lines drawn in the display have a thickness of 1 pixel. If you want to increase the thickness of the lines, increase the value of **Line Width**.

Point Symbol:

By default, nodes displayed on surfaces and data points on line or rake surfaces are represented in the display by a + sign inside a circle. If you want to modify this representation (for example, to make the nodes easier to see), you can select a different symbol in the **Point Symbol** drop-down list.

Animation Options:

There are two animation options that you can choose from. They are as follows:

All

uses a solid-tone shading representation of all geometry during mouse manipulation.

Wireframe

uses a wireframe representation of all geometry during mouse manipulation. If your computer has a graphics accelerator, you may not want to use this option; otherwise, the mouse manipulation may be very slow.

Double Buffering:

Enabling the **Double Buffering** option can dramatically reduce screen flicker during graphics updates. Note, however, that if your display hardware does not support double buffering and you turn this option on, double buffering will be done in software. Software double buffering uses extra memory.

Outer Face Culling:

This option enables you to turn off the display of outer faces in wall zones. **Outer Face Culling** is useful for displaying both sides of a slit wall. By default, when you display a slit wall, one side will "bleed" through to the other. When you enable the **Outer Face Culling** option, the display of a slit wall will show each side distinctly as you rotate the display. This option can also be useful for displaying two-sided walls (that is, walls with fluid or solid cells on both sides).

Hidden Line Removal:

If you do not use hidden line removal, ANSYS Fluent will not try to determine which lines in the display are behind others; it will display all of them, and a cluttered display will result for most 3D mesh displays. For most 3D problems, therefore, you should enable the **Hidden Line Removal** option. You should turn this option off (for optimal performance) if you are working with a 2D problem or with geometries that do not overlap.

Hidden Surface Removal:

If you do not use hidden surface removal, ANSYS Fluent will not try to determine which surfaces in the display are behind others; it will display all of them, and a cluttered display will result for most 3D mesh displays. For most 3D problems, therefore, you should enable the **Hidden Surface Removal** option. You

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

should turn this option off (for optimal performance) if you are working with a 2D problem or with geometries that do not overlap.

You can choose one of the following methods for performing hidden surface removal in the **Hidden Surface Method** drop-down list. These options vary in speed and quality, depending on the device you are using.

Hardware Z-buffer
is the fastest method if your hardware supports it. The accuracy and speed of this method is hardware-dependent. Note that if this method is not available on your computer, selecting it will cause the **Software Z-buffer** method to be used.

Painters
will show fewer edge-aliasing effects than **Hardware-Z-buffer**. This method is often used instead of **Software-Z-buffer** when memory is limited.

Software Z-buffer
is the fastest of the accurate software methods available (especially for complex scenes), but it is memory-intensive.

Z-sort only
is a fast software method, but it is not as accurate as **Software-Z-buffer**.

31.2.7.1. Graphics Device Information

If you need to know which graphics driver you are using and what graphics hardware it recognizes, you can click **Info** in the Display Options Dialog Box (p. 2573). The graphics device information will be printed in the text (console) window.

31.3. Controlling the Mouse Button Functions

A convenient feature of ANSYS Fluent is that it enables you to assign a specific function to each of the mouse buttons. According to your specifications, clicking a mouse button in the graphics window will cause the appropriate action to be taken. These functions apply only to the graphics windows; they behave differently when an XY plot or histogram is displayed. For information about the use of mouse buttons in these plots, see Plot Types (p. 1838). Clicking any mouse button in a graphics window will make that window the active window.

Important

3Dconnexion Space products (Mouse, Pilot, and Navigator) are not supported with ANSYS Fluent.

For additional information, see the following sections:
31.3.1. Button Functions
31.3.2. Modifying the Mouse Button Functions

31.3.1. Button Functions

The predefined button functions available are listed below:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mouse-rotate
Enables you to rotate the view by dragging the mouse across the screen. Dragging horizontally rotates the object about the screen's y-axis; vertical mouse movement rotates the object about the screen's x-axis. The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-dolly
Enables you to translate the view by dragging the mouse while holding down the button. The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-scroll-zoom (non-modifiable)
Enables you to use the middle scroll-wheel to zoom in and out on the graphics window based on the location of the mouse pointer.

mouse-zoom
Enables you to draw a zoom box, anchored at the point at which the button was pressed, by dragging the mouse with the button held down. When you release the button, if the dragging was from left to right, a magnified view of the area within the zoom box will fill the window. If the dragging was from right to left, the area of the window is shrunk to fit into the zoom box, resulting in a "zoomed out" view. If the mouse button is simply clicked (not dragged), the selected point becomes the center of the window.

mouse-roll-zoom
Enables you to rotate or zoom the view, depending on the direction in which you drag the mouse. If you drag the mouse horizontally, the display will rotate about the axis normal to the screen. If you drag it vertically, the display will be magnified (if you drag it down) or shrunk (if you drag it up). The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-probe
Enables you to select items from the graphics windows and request information about displayed scenes. If you have selected **short description** from the **Probe** drop-down list and then click the mouse-probe button in the graphics window, only the identity of the item on which you clicked will be printed out in the console; if you have selected **long description** instead, more detailed information about a selected item will be displayed.

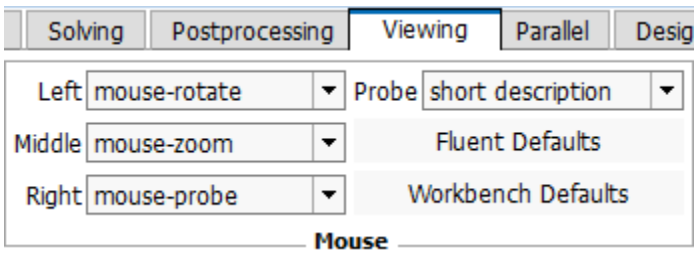
Note

A left-click will always select unless the left-mouse-button is set as **mouse-zoom** or **mouse-probe**.

31.3.2. Modifying the Mouse Button Functions

Mouse button functions are specified in the **Viewing** tab.

Viewing



For each mouse button (**Left**, **Middle**, and **Right**), select the desired function in the drop-down list. The functions are listed above. If you assign the probe function to one of the buttons, select **short description** or **long description** from the **Probe** drop-down list to indicate the amount of detail you want displayed in the console.

The new button functions take effect as soon as they are changed. That is, you do not have to redraw the graphics window to use the new functions; the appropriate function will be executed when a mouse button is subsequently clicked in a graphics window.

The **ANSYS Fluent Defaults** button functions are as follows:

Mouse Button	Key	Operation	2D Action	3D Action
Left		Drag	**Pan/dolly**	**Rotate**
Left		Click	**Select**	**Select**
Left	**Ctrl**	Click	**Add or remove selection**	**Add or remove selection**
Middle		Scroll	**Zoom**	**Zoom**
Middle		Drag	**Box-zoom**	**Box-zoom**
Middle	**Shift**	Drag	**Box-zoom**	**Box-zoom**
Middle	**Ctrl**	Drag	**Pan/dolly**	**Pan/dolly**
Right		Click	**Probe/context menu**	**Probe/context menu**
Right		Drag	**Probe/context menu**	**Probe/context menu**
Right	**Shift**	Click	**Probe/context menu**	**Probe/context menu**

The **Workbench Defaults** button functions are as follows:

Mouse Button	Key	Operation	2D Action	3D Action
Left		Drag	**Pan/dolly**	**Pan/dolly**
Left		Click	**Select**	**Select**
Left	**Ctrl**	Click	**Add or remove selection**	**Add or remove selection**
Middle		Scroll	**Zoom**	**Zoom**
Middle		Drag	**Probe**	**Rotate**
Middle	**Shift**	Drag	**Probe**	**Box-zoom**
Middle	**Ctrl**	Drag	**Probe**	**Pan/dolly**
Right		Click	**Context menu**	**Context menu**
Right		Drag	**Zoom**	**Zoom**
Right	**Shift**	Click	**Fit to center**	**Fit to center**

31.4. Viewing the Application Window

In ANSYS Fluent, the application window houses the ribbon and console, as well as multiple graphics windows, task pages, and the tree. By default, all components are displayed and one graphics window is visible. You can toggle the visibility of the toolbars, task page, console, and graphics window using in the standard toolbar. The ribbon and the tree are never fully hidden—you can hide the ribbon

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

contents using (also in the standard toolbar), but the tab names are always visible. You also have the option of viewing separate graphics windows as described in Opening Multiple Graphics Windows (p. 1786). For additional information about the various elements of the application window, see Graphical User Interface (GUI) (p. 1).

31.5. Modifying the View

ANSYS Fluent enables you to select and control the view of the scene that is displayed in the graphics window. You can modify the view by scaling, centering, rotating, translating, or zooming the display. You can also save a view that you have created, or restore or delete a view that you saved earlier. These operations are performed in the Views Dialog Box (p. 2583) (Figure 31.39: The Views Dialog Box (p. 1805)) or with the mouse, or simply using the shortcut in the graphics toolbar, as described in Selecting a View (p. 1803).

Important

You can revert to the previous view by pressing **Ctrl**+**L** while the graphics window has the main focus. You can also use the text command `view last` from the top level of the text command tree. You can use the command to revert to any of the past 20 views.

For additional information, see the following sections:

31.5.1. Selecting a View
31.5.2. Manipulating the Display
31.5.3. Controlling Perspective and Camera Parameters
31.5.4. Saving and Restoring Views
31.5.5. Mirroring and Periodic Repeats

31.5.1. Selecting a View

You can use the Views Dialog Box (p. 2583) (Figure 31.39: The Views Dialog Box (p. 1805)) to select the orientation of your display or use the drop-down available in the graphics toolbar for 3D simulations. Furthermore, you can simply click the interactive triad (Figure 31.38: Using the Triad to Change the Orientation of the Object (p. 1804)), displayed in the graphics window. The Table 31.1: Standard Views (p. 1803) relates the **Views** listed in the Views Dialog Box (p. 2583) to the views available in the graphics toolbar (see Pointer Tools (p. 7)).

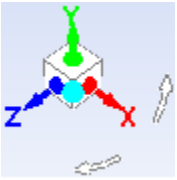
Results → Graphics → Views...

Table 31.1: Standard Views

View Listed in Dialog Box	View Shortcut in Graphics Toolbar
back	
bottom	
front	

View Listed in Dialog Box	View Shortcut in Graphics Toolbar
isometric	
left	
right	
top	

Figure 31.38: Using the Triad to Change the Orientation of the Object



To change the orientation of the object in the graphics window using the triad (Figure 31.38: Using the Triad to Change the Orientation of the Object (p. 1804)), you can

- Click an axis/semi-sphere to point it in the positive/negative direction.
- Right-click an axis/semi-sphere to point it in the negative/positive direction.
- Click the cyan iso-ball to set the isometric view.
- Click the white rotational arrows at the bottom of the triad to perform in-plane clockwise or counterclockwise 90 degree rotations.
- Left-click and hold—in the vicinity of the triad—and use the mouse to perform free-rotations in any direction. Release left mouse button to stop rotating.

Note that clicking on the X-axis will result in the +X-axis pointing towards you.

Note

For 2D cases, the drop-down and the interactive triad are not available; in a front view, the X-axis is horizontal with the positive direction to the right, the Y-axis is vertical with the positive direction pointing up, and the Z-axis is determined by the right-hand rule.

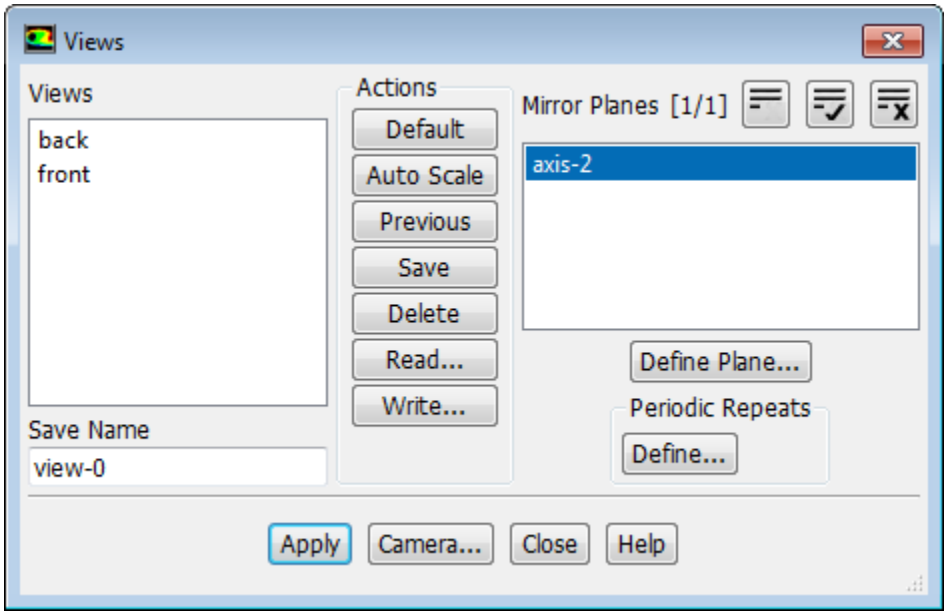
31.5.2. Manipulating the Display

Most of the manipulating activities (like scaling and centering the display) are accomplished using the Views Dialog Box (p. 2583) (Figure 31.39: The Views Dialog Box (p. 1805)).

Results → Graphics Views...

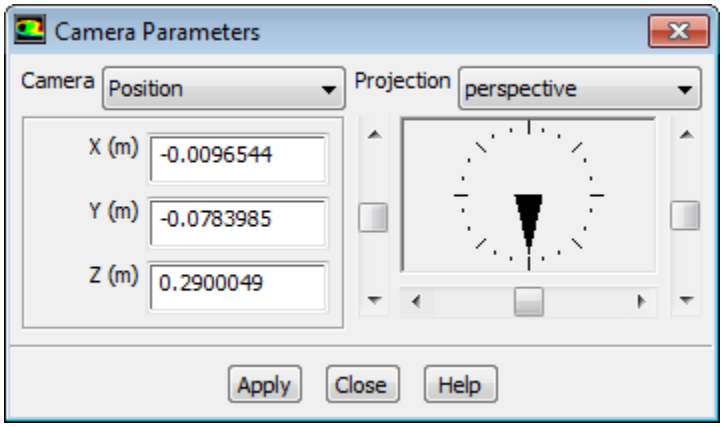
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.39: The Views Dialog Box



You can rotate, translate, and zoom the graphics display using either the mouse or the Camera Parameters Dialog Box (p. 2587) (Figure 31.40: The Camera Parameters Dialog Box (p. 1805)), which is opened from the Views Dialog Box (p. 2583).

Figure 31.40: The Camera Parameters Dialog Box



31.5.2.1. Scaling and Centering

You can scale and center the current display without changing its orientation by clicking **Auto Scale** in the Views Dialog Box (p. 2583).

31.5.2.2. Rotating the Display

Use either the mouse or the Camera Parameters Dialog Box (p. 2587) to:

- Rotate the display in any direction (in 3D)
- Rotate the display about the axis normal to the screen (in 2D)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To rotate a display with the mouse, use the button with the **mouse-rotate** function (the left button, by default). For information about changing the mouse functions, see Controlling the Mouse Button Functions (p. 1800).

- Click and drag the left mouse button in the graphics window to rotate the geometry in the display.
- You can also click and drag the left mouse button on the (x, y, z) graphics triad in the lower left corner to rotate the display.
- If you press the **Shift** key when you first click the mouse button to begin the rotation, the rotation will be constrained to a single direction (for example, you can rotate about the screen's horizontal axis without changing the position relative to the vertical axis).
- If you want to constrain the rotation of a display to be about the axis normal to the screen, you can also use the **mouse-roll-zoom** function.
- Click the appropriate mouse button and drag the mouse to the left for clockwise rotation, or to the right for counterclockwise rotation.

To rotate a 3D display using the Camera Parameters Dialog Box (p. 2587) (Figure 31.40: The Camera Parameters Dialog Box (p. 1805)) use the dial and the slider of the scales.

- To rotate about the horizontal axis at the center of the screen, move the slider on the scale to the left of the dial up or down (see Scales (p. 17) or instructions on using the scale).
- To rotate about the vertical axis at the center of the screen, move the slider on the scale below the dial to the left or right.
- To rotate about the axis at the center of and perpendicular to the screen, click the left mouse button on the indicator in the dial and drag it around the dial.

Important

The position of the slider or the dial indicator does not reflect the cumulative rotation about the axis as the slider/indicator will return to its original position when you release the mouse button.

31.5.2.2.1. Spinning the Display with the Mouse

When you use the mouse for rotation, you have the option to "push" the display into a continuous spin. This feature can be used in conjunction with video recording, or simply for interactive viewing of the domain from different angles. To use this option, use the `auto-spin?` text command:

`display` → `set` → `rendering-options` → `auto-spin?`

Then display the graphics (or, if the graphics are already displayed, you can click **Apply** in the Display Options Dialog Box (p. 2573)). The **mouse-rotate** button will then have two uses:

- To perform the standard rotation, stop dragging the mouse before you release the **mouse-rotate** button.
- To start the continuous spin, release the **mouse-rotate** button while you are still dragging the mouse. The display will continue to rotate on its own until you click any mouse button in the graphics window again. The speed of the rotation will depend on how fast you are dragging the mouse when you release the button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For smoother rotation, enable the **Double Buffering** option in the Display Options Dialog Box (p. 2573) (see Modifying the Rendering Options (p. 1798)). This will reduce screen flicker during graphics updates.

31.5.2.3. Translating the Display

By default the left mouse button is set to **mouse-dolly** in 2D. For information about changing the mouse functions, see Controlling the Mouse Button Functions (p. 1800). Click and drag the left mouse button in the graphics window to translate the geometry in the display.

In 3D, you can either change one of the button functions to **mouse-dolly** and follow the instructions above for 2D, or use the **mouse-zoom** button (the middle button by default). Click the middle button once on the point in the display that you want to move to the center of the screen. ANSYS Fluent will redisplay the graphic with that point in the center of the window. This method can also be used in 2D.

31.5.2.4. Zooming the Display

In both 2D and 3D you will use the mouse button with the **mouse-zoom** function (the middle button by default) or the **mouse-roll-zoom** function (see Controlling the Mouse Button Functions (p. 1800) for information about enabling this optional function), or the Camera Parameters Dialog Box (p. 2587) to magnify and shrink the display.

With the **mouse-zoom** function, click the middle mouse button and drag it from left to right (creating a "zoom box") to magnify the display. Figure 31.41: Zooming In (Magnifying the Display) (p. 1807) displays the correct dragging of the mouse, from upper left to lower right on the display, in order to zoom. You can also drag from lower left to upper right. After you release the mouse button, ANSYS Fluent will re-display the graphic, filling the graphics window with the portion of the display that previously occupied the zoom box.

Figure 31.41: Zooming In (Magnifying the Display)

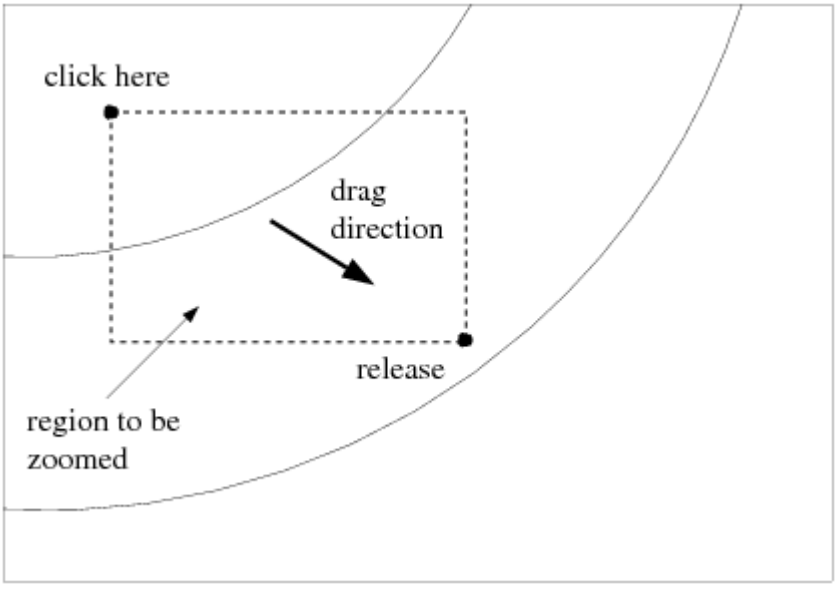


Figure 31.42: Zooming Out (Shrinking the Display)

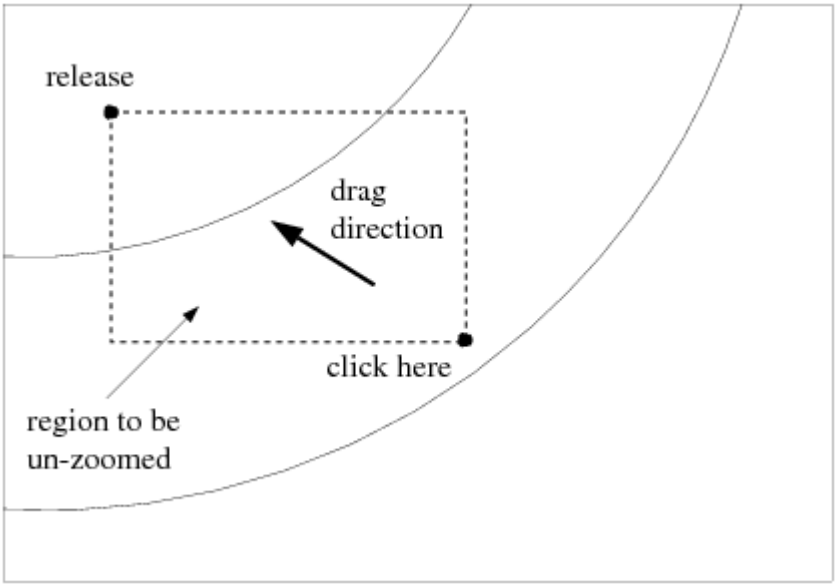


Click the middle mouse button and drag it from right to left to shrink the display. Figure 31.42: Zooming Out (Shrinking the Display) (p. 1808) displays the correct dragging of the mouse, from lower right to upper left on the display, in order to "zoom out". You can also drag from upper right to lower left. After you release the mouse button, ANSYS Fluent will redisplay the graphic, shrinking the graphical display by the ratio of sizes of the zoom box you created and the previous display.

With the **mouse-roll-zoom** function, click the appropriate mouse button and drag the mouse down to zoom in continuously, or up to zoom out. In the Camera Parameters Dialog Box (p. 2587) (Figure 31.40: The Camera Parameters Dialog Box (p. 1805)), use the scale to the right of the dial to zoom the display. Move the slider bar up to zoom in and down to zoom out.

31.5.3. Controlling Perspective and Camera Parameters

Perspective and other camera parameters are defined in the Views Dialog Box (p. 2583), which you can open by clicking **Camera...** in the Camera Parameters Dialog Box (p. 2587) (Figure 31.39: The Views Dialog Box (p. 1805)).

Results → Graphics Views...

31.5.3.1. Perspective and Orthographic Views

You may choose to display either an orthographic view or a perspective view of your graphics. To show a perspective view (the default), select **Perspective** in the **Projection** drop-down list in the Views Dialog Box (p. 2583) (Figure 31.40: The Camera Parameters Dialog Box (p. 1805)). To turn off perspective, select **Orthographic** in the **Projection** drop-down list.

31.5.3.2. Modifying Camera Parameters

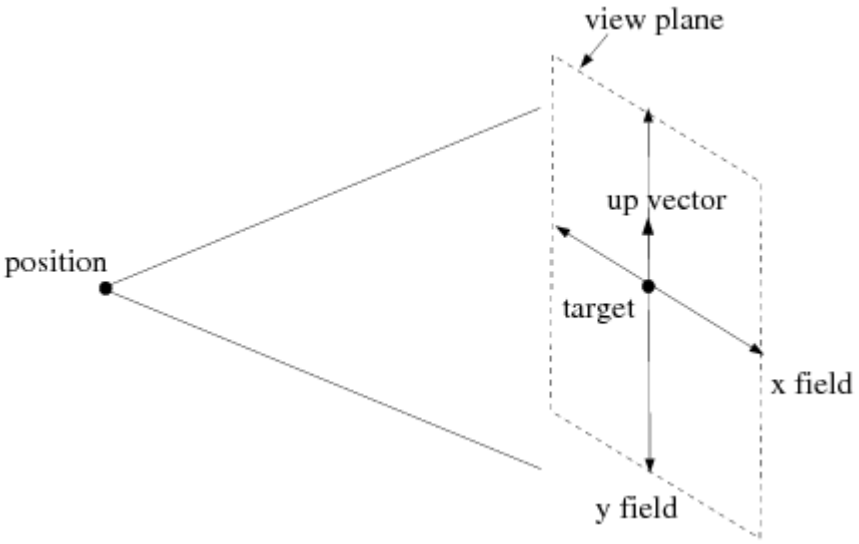
Instead of translating, rotating, and zooming the display as described in Manipulating the Display (p. 1804), you may sometimes want to modify the “camera” through which you are viewing the graphics display.

The camera is defined by four parameters: position, target, up vector, and field, as illustrated in Figure 31.43: Camera Definition (p. 1809). "Position" is the camera’s location. "Target" is the location of the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

point the camera is looking at, and "up vector" indicates to the camera which way is up. "Field" indicates the field of view (width and height) of the display.

Figure 31.43: Camera Definition



To modify the camera's position, select **Position** in the **Camera** drop-down list and specify the **X**, **Y**, and **Z** coordinates of the desired point. To modify the target location, select **Target** in the **Camera** drop-down list and specify the coordinates of the desired point. Select **Up Vector** to change the up direction. The up vector is the vector from (0,0,0) to the specified (**X,Y,Z**) point. Finally, to change the field of view, select **Field** in the **Camera** list and enter the **X** (horizontal) and **Y** (vertical) field distances.

Important

Click **Apply** after you change each camera parameter (**Position**, **Target**, **Up Vector**, and **Field**).

31.5.4. Saving and Restoring Views

After you make changes to the view shown in your graphics window, you may want to save the view so that you can return to it later. Several default views are predefined for you, and can be easily restored. All saving and restoring functions are performed with the Views Dialog Box (p. 2583) (Figure 31.39: The Views Dialog Box (p. 1805)).

Results → Graphics Views...

Important

Note that settings for mirroring and periodic repeats are not saved in a view.

31.5.4.1. Restoring the Default View

When experimenting with different view manipulation techniques, you may accidentally "lose" your geometry in the display. You can easily return to the default (front) view by clicking **Default** in the Views Dialog Box (p. 2583).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.5.4.2. Returning to Previous Views

After manipulating the display and viewing it from different angles, you can return to previous displays by clicking **Previous** in the Views Dialog Box (p. 2583).

31.5.4.3. Saving Views

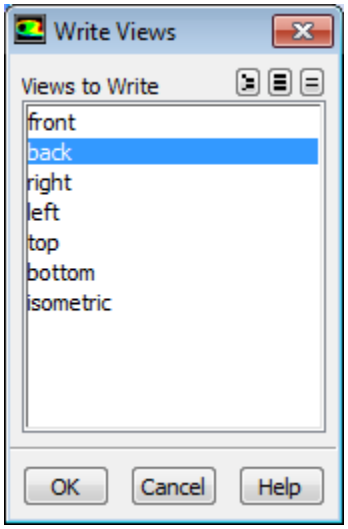
Once you have created a new view that you want to save for future use, enter a name for it in the **Save Name** field in the Views Dialog Box (p. 2583) and click **Save**. Your new view will be added to the list of **Views**, and you can restore it later as described below.

If a view with the same name already exists, you will be asked in a Question Dialog Box (p. 18) if it is OK to overwrite the existing view. If you overwrite one of the default views (top, left, right, front, and so on), be sure to save it in a view file if you want to use it in a later session. Although all views are saved to the case file, the default views are recomputed automatically when a case file is read in. Any custom view with the same name as a default view will be overwritten at that time.

As mentioned previously, all defined views will be saved in the case file when you write one. If you plan to use your views with another case file, you can write a "view file" containing just the views. You can read this view file into another Fluent session involving a different case file and restore any of the defined views, as described below.

To save a view file, click **Write...** in the Views Dialog Box (p. 2583). In the resulting Write Views Dialog Box (p. 2584) (Figure 31.44: The Write Views Dialog Box (p. 1810)), select the views you want to save in the **Views to Write** list and click **OK**. You will then use the **Select File** dialog box to specify the file name and save the view file. See The Select File Dialog Box (p. 19) for more details.

Figure 31.44: The Write Views Dialog Box



31.5.4.4. Reading View Files

If you have saved views to a view file (as described above), you can read them into your current Fluent session by clicking **Read...** in the Views Dialog Box (p. 2583), and indicating the name of the view file in The Select File Dialog Box (p. 19). If a view that you read has the same name as a view that already exists, you will be asked in a Question Dialog Box (p. 18) if it is OK to overwrite (that is, replace) the existing view.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

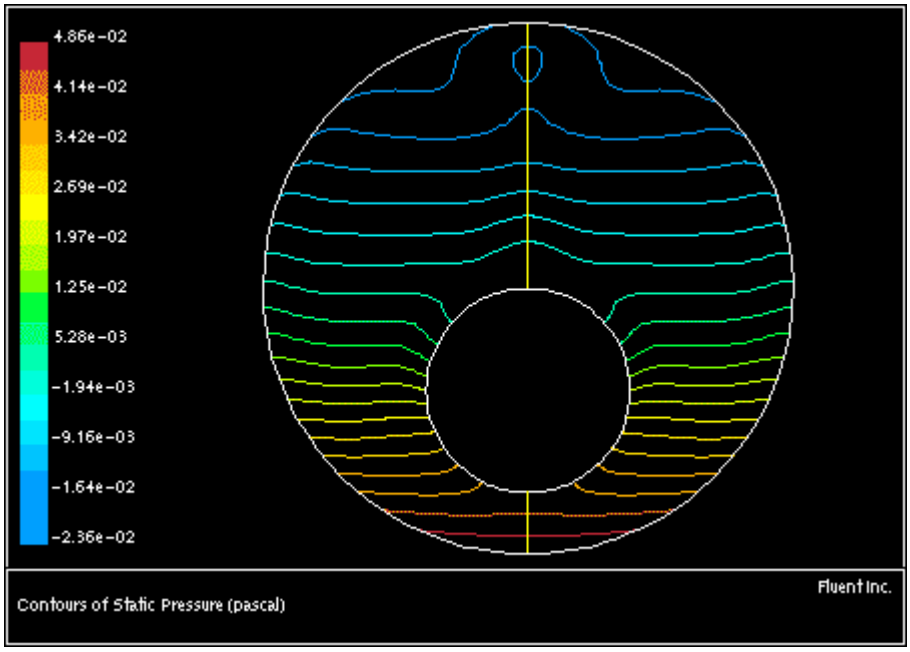
31.5.4.5. Deleting Views

If you decide that you no longer want to keep a particular view, you can delete it by selecting it in the **Views** list and clicking on **Delete**. Use this option carefully, so that you do not accidentally delete one of the predefined views.

31.5.5. Mirroring and Periodic Repeats

If you model the problem domain as a subset of the complete geometry using symmetry or periodic boundaries, you can display results on the complete geometry by mirroring or repeating the domain. For example, only one half of the annulus shown in Figure 31.45: Mirroring Across a Symmetry Boundary (p. 1811) was modeled, but the graphics are displayed on both halves. You can also define mirror planes or periodic repeats just for graphical display, even if you did not model your problem using symmetry or periodic boundaries.

Figure 31.45: Mirroring Across a Symmetry Boundary

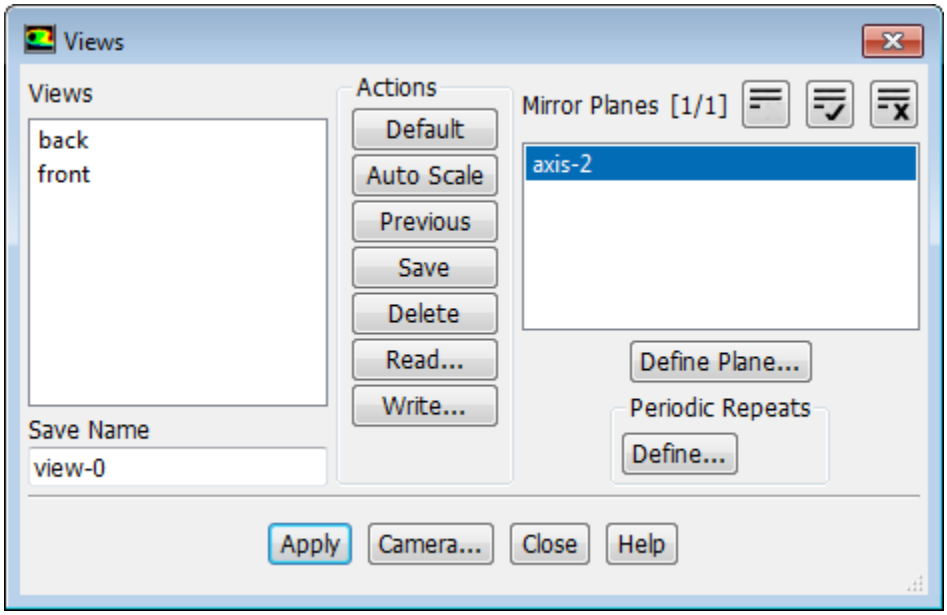


Display of symmetry and periodic repeats is controlled in the Views Dialog Box (p. 2583) (Figure 31.46: The Views Dialog Box (p. 1812)).

Results → Graphics Views...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.46: The Views Dialog Box



For a symmetric domain, all symmetry boundaries are listed in the **Mirror Planes** list. Select one or more of these boundaries as the plane(s) about which to mirror the display.

For a periodic domain, click **Define...** to open the Graphics Periodicity Dialog Box (p. 2586), to access the periodicity parameters. Specify the number of times to repeat the modeled portion by increasing the value of **Number of Repeats**. If, for example, you modeled a 90° sector of a duct and you wanted to display results on the entire duct, you would set **Number of Repeats** to 4.

In some cases, there may be multiple zones with different periodicity in the domain. For example, in turbomachinery problems with multiple blade rows using the mixing plane model, the periodic angles are different for each blade row. One blade may contain 20 blades (18° periodic angle) and other may contain 15 blades (24° periodic angle). In such cases select the required cell zone and specify the number of repeats for that particular cell zone.

When you click **Set** in the Graphics Periodicity Dialog Box (p. 2586) the graphics display will be immediately updated to show the requested periodic repeats.

Figure 31.47: Before Applying Periodicity (p. 1813) and Figure 31.48: After Applying Periodicity (p. 1813) shows the display for the sample geometry before and after applying the periodic repeats respectively. In this case the value of **Number of Repeats** is set to 6 for the 60° sector (outer part) and to a value of 4 is set for the 90° sector (inner part) of the geometry.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.47: Before Applying Periodicity

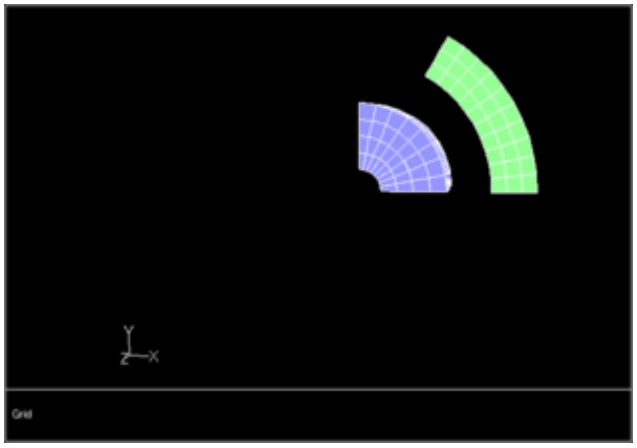


Figure 31.48: After Applying Periodicity

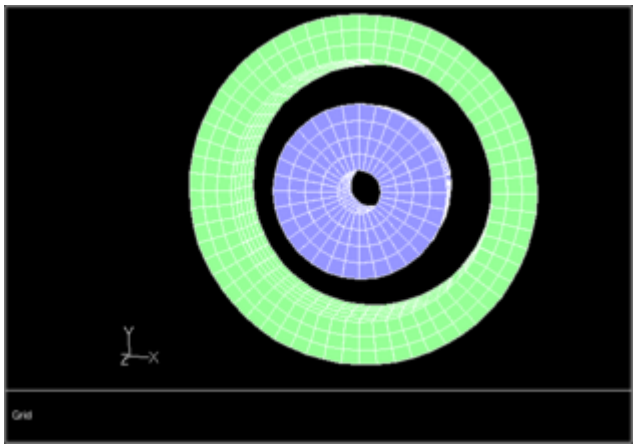


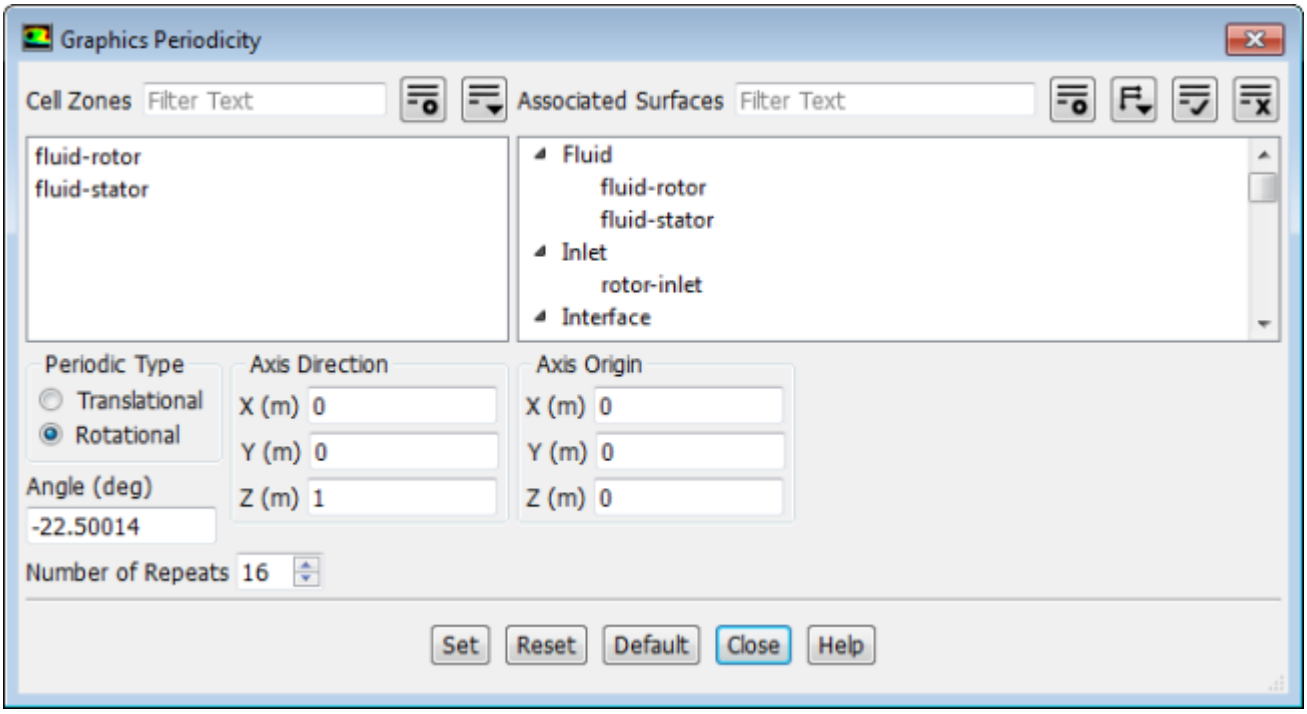
31.5.5.1. Periodic Repeats for Graphics

To define graphical periodicity for a non-periodic domain, do the following:

1. Click **Define...** under **Periodic Repeats** in the Views Dialog Box (p. 2583).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.49: The Graphics Periodicity Dialog Box



2. In the resulting Graphics Periodicity Dialog Box (p. 2586) (Figure 31.49: The Graphics Periodicity Dialog Box (p. 1814)), select the **Cell Zone** for which you want to specify the number of repeats.

   Associated Surfaces *list contains the surfaces associated with the selected cell zone. This is only informative and you cannot edit the selection of surfaces in this box.*

3. Specify **Rotational** or **Translational** as the **Periodic Type**.

4. For translational periodicity, specify the **Translation** distance of the repeated domain in the **X**, **Y**, and **Z** directions. For rotational periodicity, specify the axis about which the periodicity is defined and the **Angle** by which the domain is rotated to create the periodic repeat. For 3D problems, the axis of rotation is the vector passing through the specified **Axis Origin** and parallel to the vector from (0,0,0) to the (**X,Y,Z**) point specified under **Axis Direction**. For 2D problems, you will specify only the **Axis Origin**; the axis of rotation is the z-direction vector passing through the specified point.

5. Specify **Number of Repeats** for the selected cell zone.

6. Click **Set** in the Graphics Periodicity Dialog Box (p. 2586).

7. Follow the same procedure for other cell zones.

8. Click **Apply** in the Views Dialog Box (p. 2583) to visualize the modified display.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can delete the definition of any periodicity you have defined for graphics by clicking **Reset** in the Graphics Periodicity Dialog Box (p. 2586).

Note

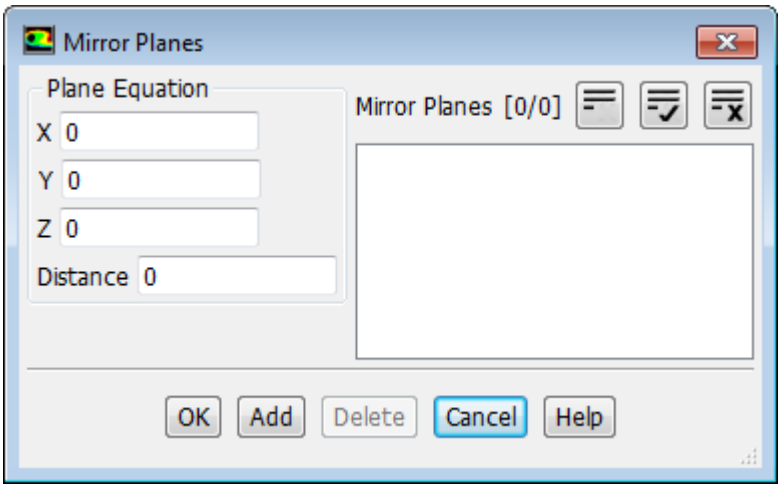
For the 3D domain with multiple periodic zones having different periodicity, ANSYS Fluent can repeat only mesh, contour and vector plots, and not the pathlines and particle tracks. Also if such domain contains, isosurfaces and clip-surfaces, that are associated with a particular cell zone, they are repeated using the same periodicity that is defined for that cell zone. However, if the surface is not associated with any cell zone, you cannot specify the periodicity for that surface.

31.5.5.2. Mirroring for Graphics

To define a mirror plane for a non-symmetric domain, do the following:

1. Click **Define Plane...** under **Mirror Planes** in the Views Dialog Box (p. 2583).

   Figure 31.50: The Mirror Planes Dialog Box

2. In the resulting Mirror Planes Dialog Box (p. 2585) (Figure 31.50: The Mirror Planes Dialog Box (p. 1815)), set the coefficients of **X**, **Y**, and **Z** and the **Distance** (of the plane from the origin) in the following equation for the mirror plane:

   $$Ax+By+Cz=\text{distance} \tag{31.1}$$

3. Click **Add** to add the defined plane to the **Mirror Planes** list. When you are done creating mirror planes, click **OK**. The newly defined plane(s) will now appear in the **Mirror Planes** list in the Views Dialog Box (p. 2583). To include the mirroring in the display, select the plane(s) and click **Apply**, as described above.

If you want to delete a mirror plane that you have defined, select it in the **Mirror Planes** list in the Mirror Planes Dialog Box (p. 2585) and click **Delete**. When you click **OK** in this dialog box, the deleted plane will be removed permanently from the **Mirror Planes** list in the Views Dialog Box (p. 2583).

31.6. Advanced Scene Composition

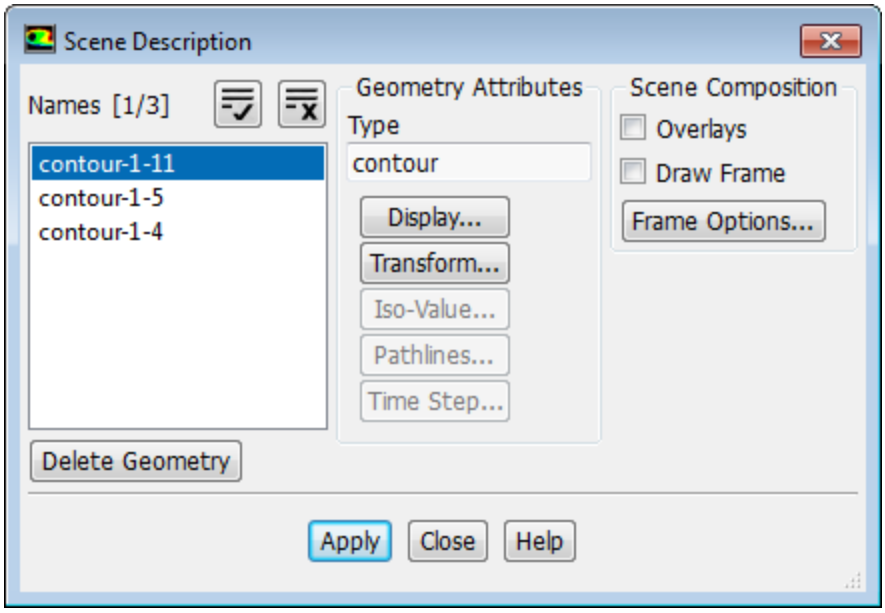
Figure 31.51: The Scene Description Dialog Box (p. 1816) allows you to create a more complex scene than what you can create using Figure 31.26: The Scene Dialog Box (p. 1781).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once you have displayed some geometric objects (meshes, surfaces, contours, vectors, and so on) in your graphics window, you may want to move them around and change their characteristics to increase the effectiveness of the scene displayed. You can use the Scene Description Dialog Box (p. 2577) (Figure 31.51: The Scene Description Dialog Box (p. 1816)) and the Display Properties Dialog Box (p. 2578) (Figure 31.52: The Display Properties Dialog Box (p. 1817)) and Transformations Dialog Box (p. 2580) (Figure 31.54: The Transformations Dialog Box (p. 1820)), which are opened from within it, to rotate, translate, and scale each object individually, as well as change the color and visibility of each object.

Viewing → Graphics → Compose...

Figure 31.51: The Scene Description Dialog Box



The Iso-Value Dialog Box (p. 2581) (Figure 31.55: The Iso-Value Dialog Box (p. 1821)), which is also opened from within the Scene Description Dialog Box (p. 2577), enables you to change the isovalue of a selected isosurface. The Pathline Attributes Dialog Box (p. 2582) (Figure 31.56: The Pathline Attributes Dialog Box (p. 1822)) lets you set some pathline attributes. The ability to make geometric objects visible and invisible is especially useful when you are creating an animation (see Animating Graphics (p. 1825)) because it enables you to add or delete objects from the scene one at a time. The ability to change the color and position of an object independently of the others in the scene is also useful for setting up animations, as is the ability to change isosurface isovalues. You will find the features in the Scene Description Dialog Box (p. 2577) useful even when you are not generating animations because they enable you to manage your graphics window efficiently. The procedure for overlaying graphics, which uses the **Scene Description** dialog box, is described in Advanced Graphics Overlays (p. 1785). (Note that you cannot use the Scene Description Dialog Box (p. 2577) to control XY plot and histogram displays.)

For additional information, see the following sections:

31.6.1. Selecting the Object(s) to be Manipulated
31.6.2. Changing an Object's Display Properties
31.6.3. Transforming Geometric Objects in a Scene
31.6.4. Modifying Iso-Values
31.6.5. Modifying Pathline Attributes
31.6.6. Deleting an Object from the Scene
31.6.7. Adding a Bounding Frame

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.6.1. Selecting the Object(s) to be Manipulated

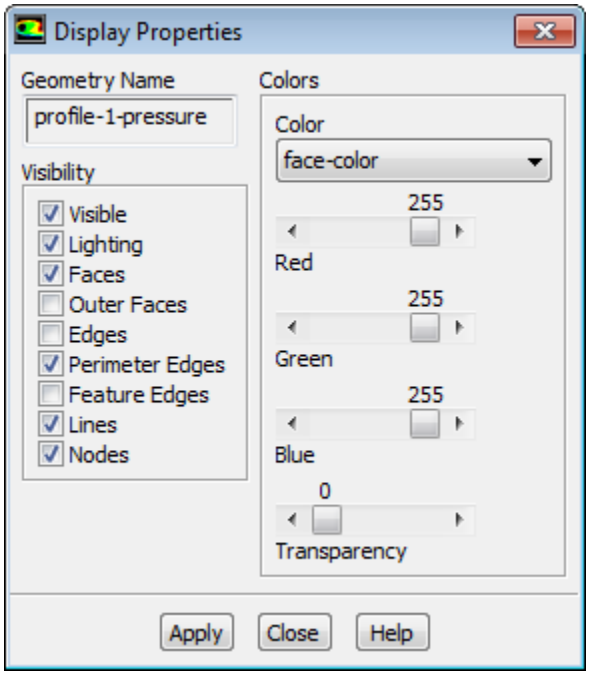
In order to manipulate the objects in the scene, you will begin by selecting the object or objects of interest in the **Names** list in the Scene Description Dialog Box (p. 2577) (Figure 31.51: The Scene Description Dialog Box (p. 1816)). The **Names** list is a list of the geometric objects that currently exist in the scene (including those that are presently invisible). If you select more than one object at a time, any operation (transformation, color specification, and so on) will apply to all the selected objects. You can also select objects by clicking on them in the graphics display using the mouse-probe button, which is, by default, the right mouse button. (See Controlling the Mouse Button Functions (p. 1800) for information about mouse button functions.) To deselect a selected object, simply click its name in the **Names** list.

When you select one or more objects (either in the **Names** list or in the display), the **Type** field will report the type of the selected object(s). Possible types for a single object include `mesh`, `surface`, `contour`, `vector`, `path`, and `text` (that is, annotation text). This information is especially helpful when you need to distinguish two or more objects with the same name. When more than one object is selected, the type displayed is `Group`.

31.6.2. Changing an Object's Display Properties

To enhance the scene in the graphics window, you can change the color, visibility, and other display properties of each geometric object in the scene. You can specify different colors for displaying the edges and faces of a mesh object to show the underlying mesh (edges) when the faces of the mesh are filled and shaded. You can also make a selected object temporarily invisible. If, for example, you are displaying the entire mesh for a complicated problem, you can make objects visible or invisible to display only certain boundary zones of the mesh without regenerating the mesh display using the Mesh Display Dialog Box (p. 2163). You can also use the visibility controls to manipulate geometric objects for efficient graphics display or for the creation of animations. These features, plus several others, are available in the Display Properties Dialog Box (p. 2578) (Figure 31.52: The Display Properties Dialog Box (p. 1817)).

Figure 31.52: The Display Properties Dialog Box



To set the display properties described above, select one or more objects in the **Names** list in the Scene Description Dialog Box (p. 2577) and then click **Display...** to open the Display Properties Dialog Box (p. 2578) for that object or group of objects.

31.6.2.1. Controlling Visibility

There are several ways for you to control the visibility of an object. All visibility options are listed under the **Visibility** heading in the Display Properties Dialog Box (p. 2578).

- To make the selected object(s) invisible, turn off the **Visible** option. To "undo" invisibility, enable the **Visible** option again.
- To turn the effect of lighting for the selected object(s) on or off, use the **Lighting** check box. You can choose to have lighting affect only certain objects instead of all of them. Note that if **Lighting** is turned on for an object such as a contour or vector plot, the colors in the plot will not be exactly the same as those in the colormap at the left of the display.
- To toggle the filled display of faces for the selected mesh or surface object(s), use the **Faces** option. Turning **Faces** on here has the same effect as turning it on for the entire mesh in the Mesh Display Dialog Box (p. 2163).
- To turn the display of outer edges on or off, use the **Outer Faces** option. This option is useful for displaying both sides of a slit wall. By default, when you display a slit wall, one side will "bleed" through to the other. When you turn off the **Outer Faces** option, the display of a slit wall will show each side distinctly as you rotate the display. This option can also be useful for displaying two-sided walls (that is, walls with fluid or solid cells on both sides).
- To turn the display of interior and exterior edges of the geometric object(s) on or off, use the **Edges** option.
- To turn the display of the outline of the geometric object(s) on or off, use the **Perimeter Edges** check box.
- To toggle the display of feature lines (described in Adding Features to an Outline Display (p. 1753)), if any, for the selected object(s), use the **Feature Edges** option.
- To toggle the display of the lines (if any) in the geometric object(s), use the **Lines** check box. Pathlines, line contours, and vectors are "lines".
- To toggle the display of nodes (if any) in the geometric object(s), use the **Nodes** check box.

Once you have set the appropriate display parameters, click **Apply** to update the graphics display.

31.6.2.2. Controlling Object Color and Transparency

The Display Properties Dialog Box (p. 2578) also lets you control an object's color and how transparent it is. All color and transparency options are listed under the **Colors** heading.

- To modify the color of faces, edges, or lines in the selected object(s), choose **face-color**, **edge-color**, **line-color**, or **node-color** in the **Color** drop-down list. The **Red**, **Green**, and **Blue** color scales will show the RGB components of the face, edge or line color, which you can modify by moving the sliders on the color scales. When you are satisfied with the color specification, click **Apply** to save it and update the display. The ability to set the colors for faces and edges can be useful when you want to have a filled display for the mesh or surface, but you also want to be able to see the mesh lines. You can achieve this effect by specifying different colors for the faces and the edges.
- To set the relative transparency of an object, select **face-color** in the **Color** drop-down list. Move the slider on the **Transparency** scale and click **Apply** to update the graphics display. An object with a transparency

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of 0 is opaque, and an object with a transparency of 100 is transparent. By specifying a high transparency value for the walls of a pipe, for example, you will be able to see contours that you have displayed on cross-sections inside the pipe. This feature is available on all platforms when the software z buffer is used for hidden surface removal, but if your display hardware supports transparency, it will be more efficient to use the hardware z buffer as the hidden surface method instead. You can select these methods in the Display Options Dialog Box (p. 2573), as described in Modifying the Rendering Options (p. 1798).

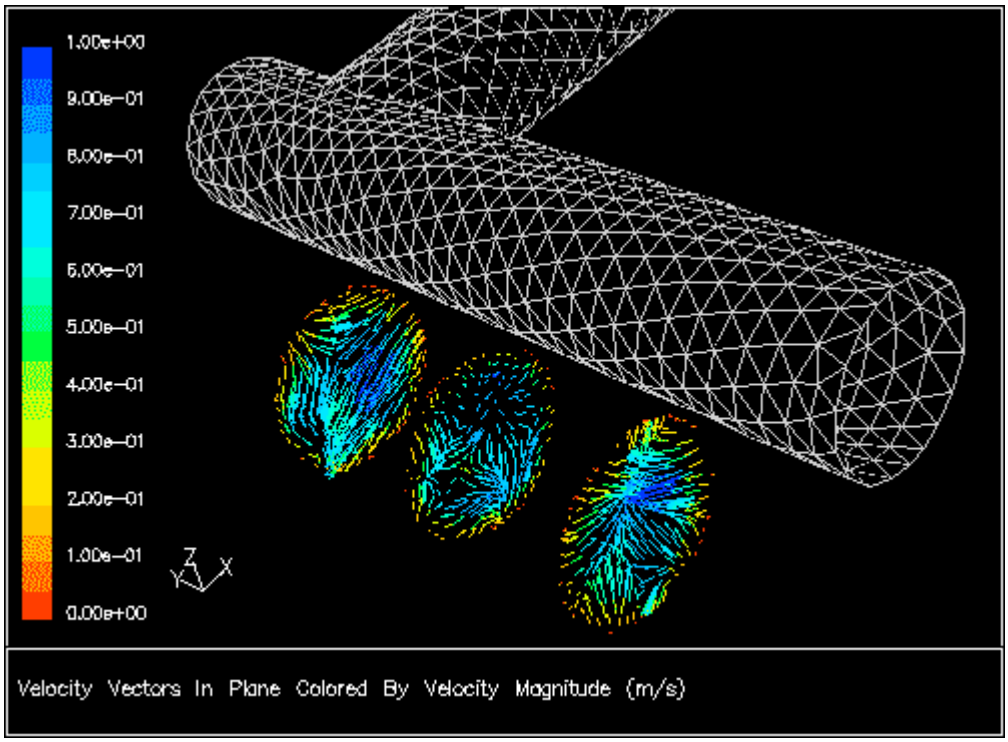
Important

If you save a picture of a display with transparent surfaces, you should *not* set the **File Type** in the Save Picture Dialog Box (p. 2568) to **Vector**.

31.6.3. Transforming Geometric Objects in a Scene

When you are composing a scene in your graphics window, you might find it helpful to move a particular object from its original position or to increase or decrease its size. For example, if you have displayed contours or vectors on cross-sections of an internal flow domain (such as a pipe), you might want to translate these cross-sections so that they will appear outside of the pipe, where they can be seen and interpreted more easily. Figure 31.53: Velocity Vectors Translated Outside the Domain for Better Viewing (p. 1819) shows such an example.

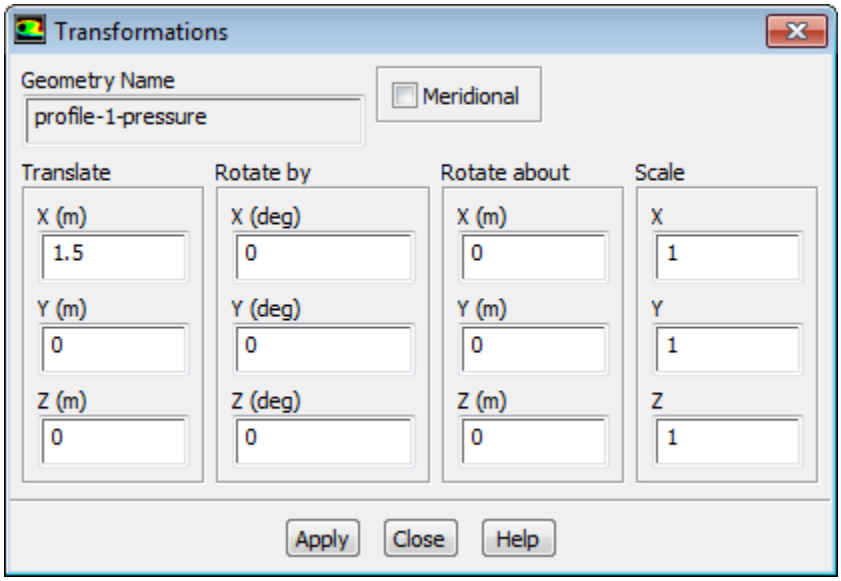
Figure 31.53: Velocity Vectors Translated Outside the Domain for Better Viewing



You can also move an object by rotating it about the x-, y-, or z-axis. If you want to display one object more prominently than the others, you can scale its size. If your geometry is rotating or has rotational symmetry, you can display the meridional view. All of these capabilities are available in the Transformations Dialog Box (p. 2580) (Figure 31.54: The Transformations Dialog Box (p. 1820)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.54: The Transformations Dialog Box



To perform the transformations described above, select one or more objects in the **Names** list in the Scene Description Dialog Box (p. 2577) and then click **Transform...** to open the Transformations Dialog Box (p. 2580) for that object or group of objects.

31.6.3.1. Translating Objects

To translate the selected object(s), enter the translation distance in each direction in the **X**, **Y**, and **Z** real number fields under **Translate**. Note that you can check the domain extents in the Scale Mesh Dialog Box (p. 2162) or the Iso-Surface Dialog Box (p. 2721). Translations are not cumulative, so you can easily return to a known state. To return to the original position, simply enter 0 in all three real number fields.

31.6.3.2. Rotating Objects

To rotate the selected object(s), enter the number of degrees by which to rotate about each axis in the **X**, **Y**, and **Z** integer number fields under **Rotate By**. You can enter any value between -360 and 360. By default, the rotation origin will be (0,0,0). If you want to spin an object about its own origin, or about some other point, specify the **X**, **Y**, and **Z** coordinates of that point under **Rotate About**.

Rotations are not cumulative, so you can easily return to a known state. To return to the original position, simply enter 0 in all three integer number fields under **Rotate By**.

31.6.3.3. Scaling Objects

To scale the selected object(s), enter the amount by which to scale in each direction in the **X**, **Y**, and **Z** real number fields under **Scale**. To avoid distortion of the object's shape, be sure to specify the same value for all three entries. Scaling is not cumulative, so you can easily return to a known state. To return the object to its original size, simply enter 1 in all three real number fields.

31.6.3.4. Displaying the Meridional View

To display the meridional view of the selected object(s), enable the **Meridional** option. This option is available only for 3D models. It is applicable to cases with a defined axis of rotation and is especially useful in turbomachinery applications.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The meridional transformation projects the selected entities onto a surface of constant angular coordinate, θ. The resultant projection thus lies in an (r, ζ) plane where ζ is in the direction of the rotation axis and r is normal to it. The value of θ used for the projection is taken as that corresponding to the minimum (r, ζ) point of the entity.

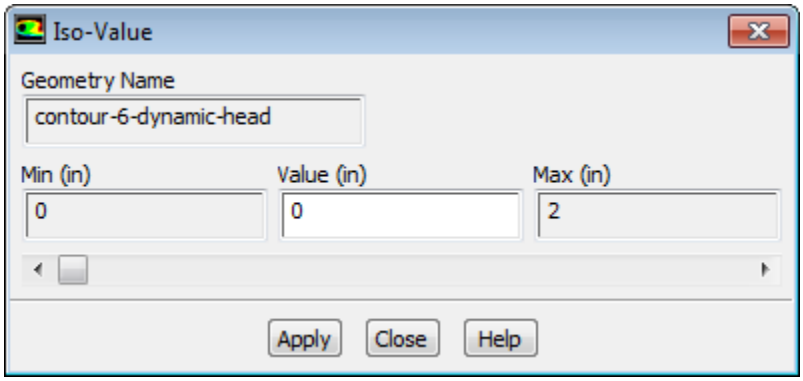
31.6.4. Modifying Iso-Values

One convenient feature that you can use to generate effective animations is the ability to generate surfaces with intermediate values between two isosurfaces with different isovalues. If the surfaces have contours, vectors, or pathlines displayed on them, ANSYS Fluent will generate and display contours, vectors, or pathlines on the intermediate surfaces that it creates.

31.6.4.1. Steps for Modifying Iso-Values

You can modify an isosurface's isovalue directly by selecting it in the **Names** list in the Scene Description Dialog Box (p. 2577) or indirectly by selecting an object displayed on the isosurface. Then click **Iso-Value...** to open the Iso-Value Dialog Box (p. 2581) (Figure 31.55: The Iso-Value Dialog Box (p. 1821)) for the selected object. Note that this button is available only if the geometric object selected in the **Names** list is an isosurface or an object on an isosurface (contour on an isosurface, for example); otherwise it is grayed out.

Figure 31.55: The Iso-Value Dialog Box



In the Iso-Value Dialog Box (p. 2581), set the new isovalue in the **Value** field, and click **Apply**. Contours, vectors, or pathlines that were displayed on the original isosurface will be displayed for the new isovalue.

31.6.4.2. An Example of Iso-Value Modification for an Animation

The ability to generate intermediate surfaces with data displayed on them is especially convenient if you want to create an animation that shows data on successive slices of the problem domain. For example, if you have solved the flow through a pipe junction and you want to create an animation that moves through one of the pipes (along the *y*-axis) and displays pressure contours on several cross-sections, you can use the following procedure:

1. Generate a surface of constant *y* coordinate (such as the *y* coordinate at the pipe inlet) using the Iso-Surface Dialog Box (p. 2721).

2. Use the Contours Dialog Box (p. 2676) to generate contours of static pressure on this isosurface and manipulate the graphics display to the desired view.

3. Open the Animate Dialog Box (p. 2567) and create key frame 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In the Scene Description Dialog Box (p. 2577), select the contour in the **Names** list and click **Iso-Value...** to open the Iso-Value Dialog Box (p. 2581).

5. Change the value of the isovalue to the *y* coordinate at the other end of the pipe, and click **Apply**. You will see the contours of static pressure at the new *y* coordinate.

6. Set key frame 10 in the Animate Dialog Box (p. 2567).

7. Play back the animation.

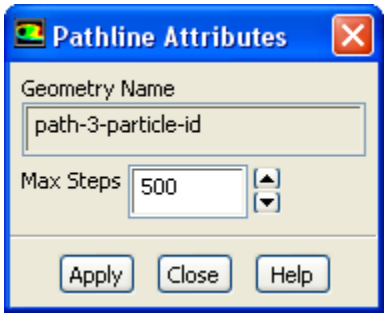
When you play back the animation, ANSYS Fluent will create the intermediate frames showing contours of static pressure on the slices between the two ends of the pipe. Ten slices will be shown in succession, all with contours displayed on them.

Using the Sweep Surface Dialog Box (p. 2565) to animate the display of contours or vectors on a surface that sweeps through the domain may be more convenient than the procedure described above. See Displaying Results on a Sweep Surface (p. 1782) for details.

31.6.5. Modifying Pathline Attributes

If you are creating animations of existing pathlines, you may want to change the number of steps used in the computation of the pathlines. This enables you to animate pathlines advancing through the domain. To do so, select the pathlines in the **Names** list in the Scene Description Dialog Box (p. 2577) and then click **Pathlines...** to open the Pathline Attributes Dialog Box (p. 2582) (Figure 31.56: The Pathline Attributes Dialog Box (p. 1822)).

Figure 31.56: The Pathline Attributes Dialog Box



In the Pathline Attributes Dialog Box (p. 2582), set the new maximum number of steps for pathline computation (**Max Steps**). After you change the value and click **Apply**, the selected pathline will be recomputed and redrawn.

31.6.5.1. An Example of Pathline Modification for an Animation

You can use the following procedure to animate pathlines from step 2 to step 101 (for example):

1. Generate the plot of pathlines using the Pathlines Dialog Box (p. 2771).

2. In the Scene Description Dialog Box (p. 2577), select the pathlines in the **Names** list and click **Pathlines...** to open the Pathline Attributes Dialog Box (p. 2582).

3. Change the value of the maximum number of steps to 2, and click **Apply**.

4. Open the Animate Dialog Box (p. 2567) and create key frame 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. In the Pathline Attributes Dialog Box (p. 2582), change the value of the maximum number of steps to 101, and click **Apply**.

6. Set key frame 100 in the Animate Dialog Box (p. 2567).

7. Play back the animation.

When you play back the animation, ANSYS Fluent will animate the pathlines so that they advance one step in each frame.

31.6.6. Deleting an Object from the Scene

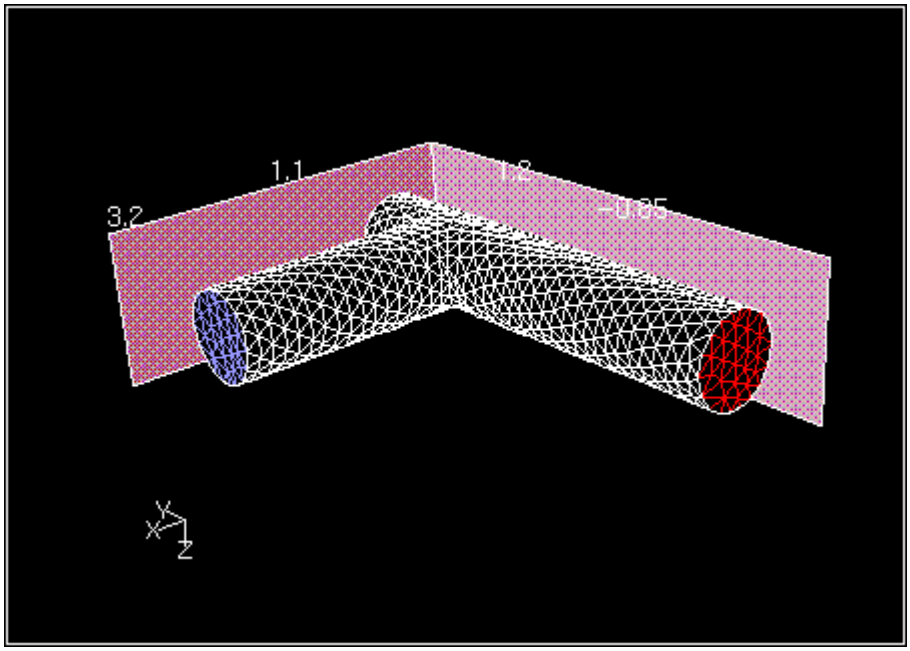
If you are composing a complex scene with overlays and find that you no longer want to keep one of the objects, it is possible to delete it without affecting any of the other objects in the scene. The ability to delete individual objects is especially useful if you have overlays on and you generate an unwanted object (for example, if you generate contours of the wrong variable). You can simply delete the unwanted object and continue your scene composition, instead of starting over from the beginning. Note that it is also possible to make objects temporarily invisible, as described in Controlling Visibility (p. 1818).

Object deletion is performed in the Scene Description Dialog Box (p. 2577) (Figure 31.51: The Scene Description Dialog Box (p. 1816)). To delete an object from the scene, select it in the **Names** list and then click **Delete Geometry**. The selected name will disappear from the **Names** list, and the display will be updated immediately.

31.6.7. Adding a Bounding Frame

ANSYS Fluent enables you to add a bounding frame around your displayed domain. You may also include measure markings on the bounding frame to indicate the length, height, and/or width of the domain, as shown in Figure 31.57: Graphics Display with Bounding Frame (p. 1823).

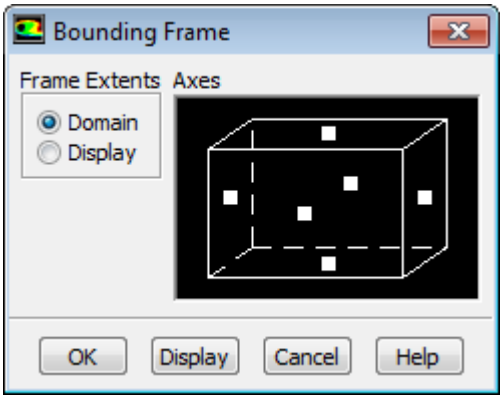
Figure 31.57: Graphics Display with Bounding Frame



To add a bounding frame to your display, you will follow the procedure below:

1. Click **Frame Options...** in the Scene Description Dialog Box (p. 2577) (Figure 31.51: The Scene Description Dialog Box (p. 1816)) to open the Bounding Frame Dialog Box (p. 2582) (Figure 31.58: The Bounding Frame Dialog Box (p. 1824)).

Figure 31.58: The Bounding Frame Dialog Box



2. Under **Frame Extents** in the Bounding Frame Dialog Box (p. 2582), select **Domain** or **Display** to indicate whether the bounding frame should encompass the domain extents or only the portion of the domain that is shown in the display.

3. In the **Axes** portion of the Bounding Frame Dialog Box (p. 2582), specify the frame boundaries and measurements to be shown in the display:

   - Indicate the bounding plane(s) (for example, the *x*-*z* and *y*-*z* planes shown in Figure 31.57: Graphics Display with Bounding Frame (p. 1823)) to be displayed by clicking on the white square on the appropriate plane of the box shown under the **Axes** heading. You can use any of the mouse buttons. The square will turn red to indicate that the associated bounding plane will be displayed in the graphics window.

   - Specify where you would like to see the measurement annotations by clicking on the appropriate edge of the box. The edge will turn red to indicate that the markings will be displayed along that edge of the displayed geometry.

   Important

   If you have trouble determining which square or edge corresponds to which location in your domain, you can easily find out by displaying one or two bounding planes to get your bearings. You can then select the appropriate objects to obtain the final display.

4. Click **Display** to update the display with the current settings. If you are not satisfied with the frame, repeat steps 2 and/or 3 and click **Display** again.

5. Once you are satisfied with the bounding frame that is displayed, click **OK** to close the Bounding Frame Dialog Box (p. 2582) and save the frame settings for future displays.

6. If you want to include the bounding frame in all subsequent displays, enable the **Draw Frame** option in the Scene Description Dialog Box (p. 2577) and click **Apply**. If this option is not enabled, the bounding box will appear only in the current display; it will not be redisplayed when you generate a new display (unless you have overlays enabled).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

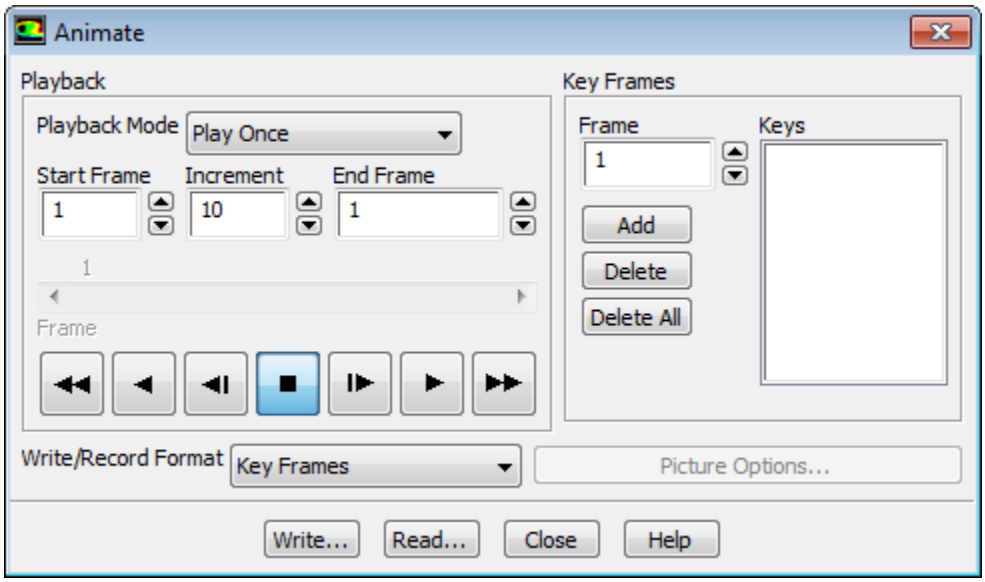
The bounding planes and axis annotations will appear in the **Names** list of the Scene Description Dialog Box (p. 2577), and you can manipulate them in the same way as any other geometric object in the display. For example, you can use the Display Properties Dialog Box (p. 2578) to change the face color of a bounding plane or to make it transparent (see Changing an Object's Display Properties (p. 1817)).

31.7. Animating Graphics

To generate animations that progress from one static view of the graphics display to the next, you can set up "key frames" (individual static images) using the Animate Dialog Box (p. 2567) (Figure 31.59: The Animate Dialog Box (p. 1825)).

Results → Animations → Scene Animation → Edit...

Figure 31.59: The Animate Dialog Box



You can compose a scene in the graphics window and define it as a single key frame. Then, modify the scene by moving or scaling objects, making some objects invisible or visible, changing colors, changing the view, or making other changes, and define the new scene as another key frame. ANSYS Fluent can then interpolate smoothly between the two frames that you defined, creating a specified number of intermediate frames.

Another method of generating animations is to automatically generate surfaces with intermediate values between two isosurfaces with different isovalues. See Modifying Iso-Values (p. 1821) for details. See Displaying Results on a Sweep Surface (p. 1782) for information about displaying the mesh, contours, or vectors on a surface that sweeps through the domain. If you want to create a graphical animation of the solution over time, you can use Figure 28.43: The Animation Definition Dialog Box (p. 1648) to set up the graphical displays that you want to use in the animation. You can choose the type of display you want to animate by selecting it from the **Animation Object** list or by creating a new animation object. For details on animating the solution, see Animating the Solution (p. 1647). For more information on generating, displaying, and saving pathlines and particle tracks, refer to Displaying Pathlines (p. 1772).

For additional information, see the following sections:

31.7.1. Creating an Animation
31.7.2. Playing an Animation
31.7.3. Saving an Animation

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.7.4. Reading an Animation File
31.7.5. Notes on Animation

31.7.1. Creating an Animation

You can define any number of key frames (up to 3000) to create your animation. By assigning the appropriate numbers to the key frames, you provide the information ANSYS Fluent needs to create the correct number of intermediate frames. For example, to create a simple animation that begins with a front view of an object, moves to a side view, and ends with a rear view of the object, you would follow the procedure outlined below:

1. Determine the number of frames that you want in the animation. For this example, consider the animation to be 31 frames.

2. Determine the number of key frames that you need to specify. In this example, you will specify three: one showing the front view, one showing the side view, and one showing the rear view.

3. Determine the appropriate key frame numbers to assign to the 3 specified frames. Here, the front view will be specified as key frame 1, the side view will be key frame 16, and the rear view will be key frame 31.

4. Compose the scenes for each view to be used as a key frame. You can use the Scene Description Dialog Box (p. 2577) (see Advanced Scene Composition (p. 1815)) and the Views Dialog Box (p. 2583) (see Modifying the View (p. 1803)) to modify the display, and any other dialog boxes or commands to create contours, vectors, pathlines, and so on to be included in each scene. After you complete each scene, create the appropriate key frame by setting the **Frame** number and clicking **Add** under **Key Frames** in the Animate Dialog Box (p. 2567). For special considerations related to key frame definition, see Notes on Animation (p. 1829).

   Important

   Be sure to change the **Frame** number before clicking **Add**, or you will overwrite the last key frame that you created.

   You can check any of the key frames that you have created by selecting it in the **Keys** list. The selected key frame will be displayed in the graphics window.

5. When you complete the animation, you can play it back as described in Playing an Animation (p. 1826) and/or save it as described in Saving an Animation (p. 1828).

31.7.1.1. Deleting Key Frames

If, during the creation of your animation, you want to delete one of the key frames that you have defined, select the key frame in the **Keys** list and click **Delete**. If you want to delete all key frames and start over again, click **Delete All**.

31.7.2. Playing an Animation

Once you have defined the key frames (as described in Creating an Animation (p. 1826)) or read in a previously created animation file (as described in Reading an Animation File (p. 1829)), you can play back the animation and ANSYS Fluent will interpolate between the frames that you specified to complete the animation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To play the animation once through from start to finish, click the “play” button under the **Playback** heading in the Animate Dialog Box (p. 2567). (The buttons function in a way similar to those on a standard video cassette player. “Play” is the second button from the right—a single triangle pointing to the right.) To play the animation backwards once, click the “play reverse” button (the second from the left—a single triangle point to the left). As the animation plays, the **Frame** scale shows the number of the frame that is currently displayed, as well as its relative position in the entire animation. If, instead of playing the complete animation, you want to jump to a particular key frame, move the **Frame** slider bar to the desired frame number, and the frame corresponding to the new frame number will be displayed in the graphics window.

Additional options for playing back animations are described below. Be sure to check Notes on Animation (p. 1829) as well for important notes about playing back animations.

31.7.2.1. Playing Back an Excerpt

You may sometimes want to play only one portion of a long animation. To do this, you can modify the **Start Frame** and the **End Frame** under the **Playback** heading in the Animate Dialog Box (p. 2567). For example, if your animation contains 50 frames, but you want to play only frames 20 to 35, you can set **Start Frame** to 20 and **End Frame** to 35. When you play the animation, it will start at frame 20 and finish at frame 35.

31.7.2.2. "Fast-Forwarding" the Animation

You can "fast-forward" or "fast-reverse" the animation by skipping some of the frames during playback. To fast-forward the animation, set the **Increment** and click the fast-forward button. If, for example, your **Start Frame** is 1, your **End Frame** is 15, and your **Increment** is 2, when you click the fast-forward button (the last button on the right—two triangles pointing to the right), the animation will show frames 1, 3, 5, 7, 9, 11, 13 and 15. Clicking on the fast-reverse button (the first button on the left—two triangles pointing to the left) will show frames 15, 13, 11,...1.

31.7.2.3. Continuous Animation

If you want the playback of the animation to repeat continuously, there are two options available.

- To continuously play the animation from beginning to end (or from end to beginning, if you use one of the reverse play buttons), select **Auto Repeat** in the **Playback Mode** drop-down list in the Animate Dialog Box (p. 2567).
- To play the animation back and forth continuously, reversing the playback direction each time, select **Auto Reverse** in the **Playback Mode** drop-down list.

To turn off the continuous playback, select **Play Once** in the **Playback Mode** list. This is the default setting.

31.7.2.4. Stopping the Animation

To stop the animation during playback, click the "stop" button (the square in the middle of the playback control buttons). If your animation contains very complicated scenes, there may be a slight delay before the animation stops.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.7.2.5. Advancing the Animation Frame by Frame

To advance the animation manually frame by frame, use the third button from the right (a vertical bar with a triangle pointing to the right). Each time you click this button, the next frame will be displayed in the graphics window. To reverse the animation frame by frame, use the third button from the left (a left-pointing triangle with a vertical bar). Frame-by-frame playback enables you to freeze the animation at points that are of particular interest.

31.7.3. Saving an Animation

Once you have created your animation, you can save it in any of the following formats:

- Animation file containing the key frame descriptions
- Picture files, each containing a frame of the animation
- MPEG file containing each frame of the animation
- Video (see Creating Videos (p. 1829))

31.7.3.1. Animation File

You can save the key frame definitions to a file that can be read back into ANSYS Fluent (see Reading an Animation File (p. 1829)) when you want to replay the animation. Since the animation file will contain only the key frame definitions, you must be sure that you have a case and data file containing the necessary surfaces and other information referred to by the key frame descriptions.

To write an animation file, select **Key Frames** in the **Write/Record Format** drop-down list in the Animate Dialog Box (p. 2567), and click **Write...**. In The Select File Dialog Box (p. 19), specify the name of the file and save it.

31.7.3.2. Picture File

You can also generate a picture file for each frame in the animation. This feature enables you to save your animation frames to picture files used by an external animation program such as ImageMagick. To save the animation as a picture file, follow these steps:

1. Select **Picture Files** in the **Write/Record Format** drop-down list in the Animate Dialog Box (p. 2567).
2. If necessary, click **Picture Options...** to open the Save Picture Dialog Box (p. 2568) and set the appropriate parameters for saving the picture files. (If you are saving picture files for use with ImageMagick, for example, you may want to select the window dump format. See Window Dumps (Linux Systems Only) (p. 106) for details.) Click **Apply** in the Save Picture Dialog Box (p. 2568) to save your modified settings.

   Important

   Do not click **Save...** in the Save Picture Dialog Box (p. 2568). You will save the picture files from the Animate Dialog Box (p. 2567) in the next step.

3. In the Animate Dialog Box (p. 2567), click **Write...**. In The Select File Dialog Box (p. 19), specify the filename and click **OK** to save the files. (See Window Dumps (Linux Systems Only) (p. 106) for information about

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specifying filenames that increment automatically as additional pictures are saved.) ANSYS Fluent will replay the animation, saving each frame to a separate file.

31.7.3.3. MPEG File

It is also possible to save all of the frames of the animation in an MPEG file, which can be viewed using an MPEG decoder such as **mpeg_play**. Saving the entire animation to an MPEG file will require less disk space than storing the individual window dump files (using the picture method), but the MPEG file will yield lower-quality images. To save the animation to an MPEG file, follow these steps:

1. Select **MPEG** in the **Write/Record Format** drop-down list in the Animate Dialog Box (p. 2567).

2. In the Animate Dialog Box (p. 2567), click **Write...**. In The Select File Dialog Box (p. 19), specify the filename, and click **OK** to save the files.

   ANSYS Fluent replays the animation and saves each frame to a separate scratch file; it then combines all of the files into a single MPEG file.

31.7.4. Reading an Animation File

If you have saved the key frames defining an animation to an animation file (as described in Saving an Animation (p. 1828)), you can read that file back in at a later time (or in different session) and play the animation. Before reading in an animation file, be sure that the current case and data contain the surfaces and any other information that the key frame description refers to.

To read an animation file, click **Read...** in the Animate Dialog Box (p. 2567). In The Select File Dialog Box (p. 19), specify the name of the file to be read.

31.7.5. Notes on Animation

When you are creating and playing back animations, note the following:

- For smoother animations, enable the **Double Buffering** option in the Display Options Dialog Box (p. 2573) (see Modifying the Rendering Options (p. 1798)). This will reduce screen flicker during graphics updates.

- When you are defining key frames, you must create all geometric objects that will be used in the animation before you create any key frames. You cannot create a key frame using one set of geometric objects and then generate a new geometry (such as a vector plot) and include that in another key frame. Create all geometric objects first, and then use the Display Properties Dialog Box (p. 2578) to control the visibility of the objects in each key frame (see Controlling Visibility (p. 1818)).

- A single animation sequence can contain up to 3000 key frames.

- When you play back an animation, the colormap used will be the one that is currently active, *not* the one that was active during "recording."

31.8. Creating Videos

Tools are available for creating videos from ANSYS Fluent. This section is a guide to video creation using the new video capabilities. It assumes that you have a ready-to-use video system, and that you are familiar with this system, including the special video hardware and software installed on your computer. The main use for this feature is to record an animation that you have created using the Animate Dialog Box (p. 2567) (as described in Animating Graphics (p. 1825)). This section will describe issues involved in

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

recording animations to video, the kind of video equipment you will need, and the procedures for creating a video using ANSYS Fluent.

Important

Video creation is not currently available in Windows versions of ANSYS Fluent.

For additional information, see the following sections:

31.8.1. Recording Animations To Video
31.8.2. Equipment Required
31.8.3. Recording an Animation with ANSYS Fluent

31.8.1. Recording Animations To Video

Recording an animation involves copying the computer-generated images to videotape so that you can view the animation with a VCR, or another type of tape player. This task is not an easy one, as there are several issues that should be addressed in order to create an acceptable video. A couple of these issues are described in the following sections.

31.8.1.1. Computer Image vs. Video Image

The computer monitor uses a different video signal than the video tape recorder (VTR). Most computers use an RGB-component, non-interlaced signal with high resolution and a high refresh rate. A VTR typically uses a standard broadcast video signal (such as NTSC or PAL), which has an interlaced, composite signal with lower resolution and a lower refresh rate. In order to send the computer image to the VTR for recording, the computer has to produce a video signal in the proper format. This requires extra hardware, which, in many cases, converts RGB component video to standard broadcast video, resulting in a lower quality image. A solution to this problem is to make sure that the image you are recording does not have small text, or too much small detail that will be hard to see on video. Sometimes it is best to zoom in on an area of interest in a large image and animate just that portion.

Another problem is that RGB-component video has a larger color space (or color gamut) than standard broadcast video. This means that some colors may get "clipped" when an image is converted to broadcast video, resulting in washed-out colors, or color bleeding. The solution is to try to make sure that the colors fall within the color space of the video format, and are not oversaturated. Some picture controls that can help you do this are available in ANSYS Fluent. These controls will be discussed in Check the Picture Quality (p. 1836).

31.8.1.2. Real-Time vs. Frame-By-Frame

If the images in the animation can be rendered fast enough on the computer screen, it may be possible to record the animation in real-time. This is as simple as placing the video tape recorder (VTR) in record mode, and playing the animation on the computer screen. This also requires scan-converting hardware that will convert the scan lines of the computer screen to a video signal sent to the VTR.

In many cases, however, the animation cannot be played back on the computer screen in real-time. To create a video that plays the animation at a desirable speed, the animation must be recorded frame-by-frame. This involves sending one frame to the VTR, instructing it to record the frame at a specific point on the tape, then backing up the VTR to repeat the procedure with the next frame. This process takes quite a bit longer than real-time recording, but the result can be a much smoother video animation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.8.2. Equipment Required

In general, recording an animation to video requires a system with the following hardware components:

Computer
with video hardware to produce the video signal.

Editing VTR
(video tape recorder) that supports frame-accurate recording.

VTR Controller
which enables computer software to control the recording process.

Two VTR controller models are supported by ANSYS Fluent: the V-LAN controller developed by Videomedia, Inc., and the MiniVAS/MiniVAS-2 controller developed by the V.A.S. Group. ANSYS Fluent assumes that your recording system is set up as shown in Figure 31.60: Recording System with V-LAN Controller (p. 1831) for a system with a V-LAN controller or as shown in Figure 31.61: Recording System with MiniVAS/MiniVAS-2 Controller (p. 1831) for a system with a MiniVAS controller.

Figure 31.60: Recording System with V-LAN Controller

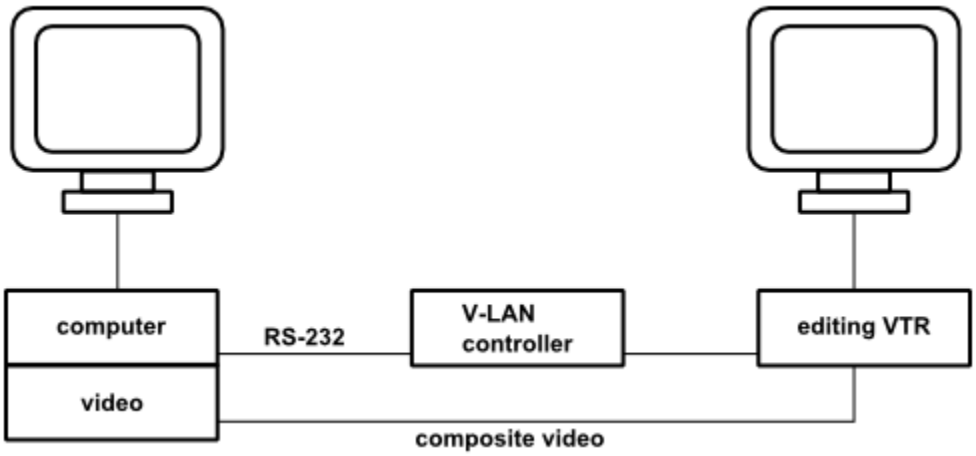


Figure 31.61: Recording System with MiniVAS/MiniVAS-2 Controller

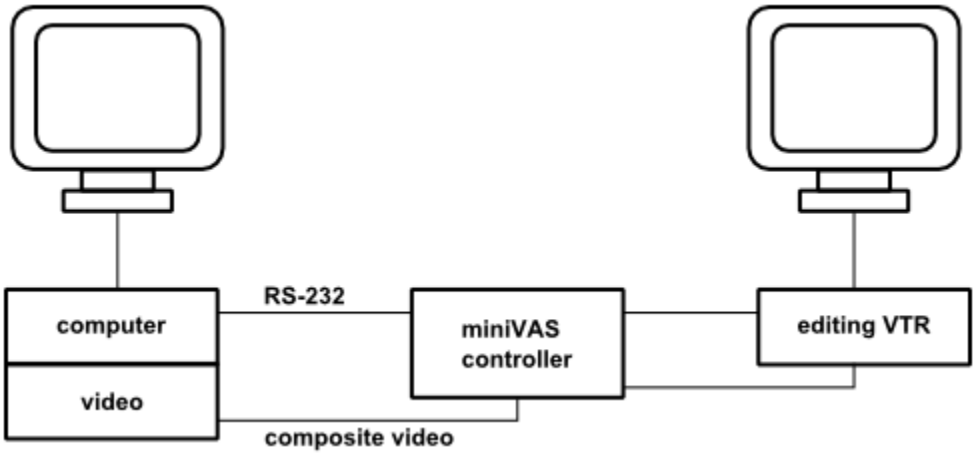


Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.8.3. Recording an Animation with ANSYS Fluent

The procedure for recording an animation using ANSYS Fluent is as follows:

- Create an Animation (p. 1832)
- Open a Connection to the VTR Controller (p. 1833)
- Set Up Your Recording Session (p. 1833)
- Check the Picture Quality (p. 1836)
- Make Sure Your Tape is Formatted (Preblacked) (p. 1837)
- Start the Recording Session (p. 1837)

Each step is described in detail in the following sections.

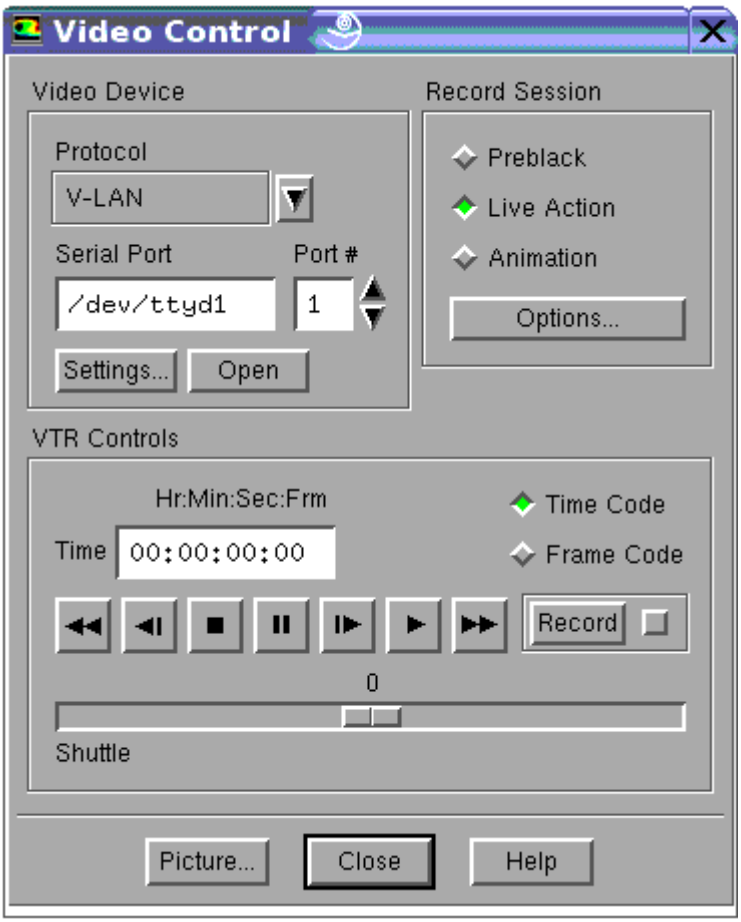
31.8.3.1. Create an Animation

When recording animations to video, you must first create your animation. It's also a good idea to play it back a couple times to make sure you are satisfied with it, and to save the animation key frame definitions to a file for later use (see Creating an Animation (p. 1826)).

When you are ready to record the animation, you can select **Video** in the **Write/Record Format** drop-down list found in the Animate Dialog Box (p. 2567). When you do so, the name of the **Write...** button will change to **Record...**, and you can click **Record...** to display the Video Control Dialog Box (p. 2833) (Figure 31.62: The Video Control Dialog Box (p. 1833)) used for video creation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.62: The Video Control Dialog Box



31.8.3.2. Open a Connection to the VTR Controller

The procedure for connecting to your VTR controller is as follows:

1. Select the protocol used by your VTR controller using the **Protocol** drop-down list.

2. Check the settings for your VTR controller by clicking on the **Settings...** button. For V-LAN, this will display the V-LAN Settings Dialog Box (p. 2836), and for MiniVAS, it will display the MiniVAS Settings Dialog Box (p. 2742).

3. Select the RS-232 serial port used to connect the VTR controller to your computer. Usually, the serial port is identified by a file name such as `/dev/ttyd1` for serial port 1, and `/dev/ttyd2` for serial port 2. If this is the case on your system, you can simply set the value of **Port #**; otherwise, you can type a new file name in the **Serial Port** text entry. Make sure that you have the proper Linux read/write permissions for the file.

4. Open a connection to the VTR controller by clicking the **Open** button. If successful, a line will be printed out in the console window that reports the VTR controller protocol version and the VTR device ID.

31.8.3.3. Set Up Your Recording Session

Once you have established a connection to the VTR controller, you can set up your recording session. There are three types of recording sessions, as described below:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Preblack
is the process of formatting a tape by laying down a time code onto the tape. A tape must be formatted before any frame-accurate editing, including frame-by-frame animation, can be performed. During this process, one usually records a black video signal onto the tape as well, therefore the name "preblack". When you select this option, the current graphics window will be cleared to black. You can use the window to send your black video signal to the VTR.

Important

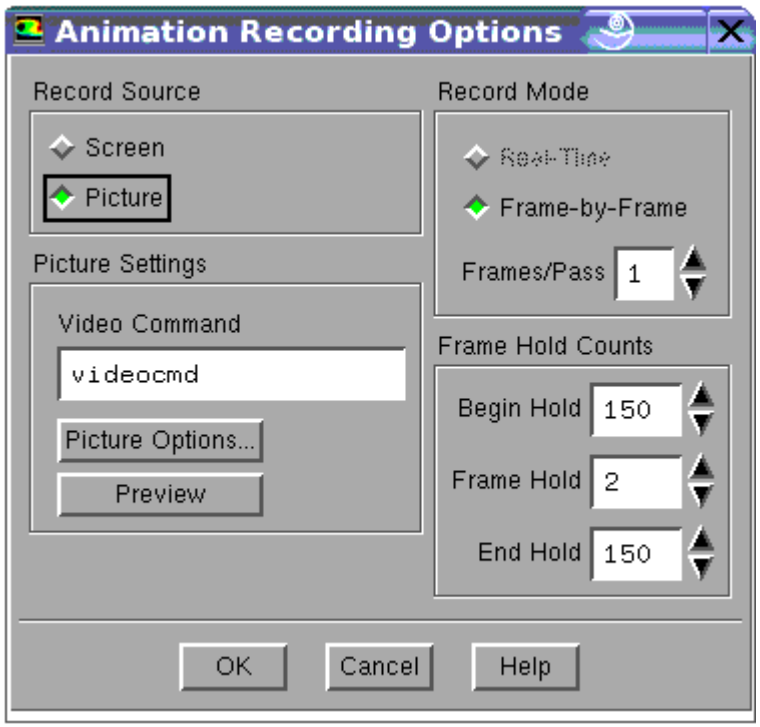
When you preblack a previously formatted tape, a new time code will be written and any previously recorded video will be destroyed.

Live Action
Enables you to record a live ANSYS Fluent session, which can be used for demonstration. This option requires your computer's video hardware to have a scan converter that will send the computer display image to your VTR system.

Animation
Plays an animation that you have created, and record it onto your VTR system.

The **Options...** button in the Video Control Dialog Box (p. 2833) is used to display the Animation Recording Options Dialog Box (p. 2668) (Figure 31.63: The Animation Recording Options Dialog Box (p. 1834)):

Figure 31.63: The Animation Recording Options Dialog Box



There are three parts to setting up your animation recording session:

1. Select the recording source.

2. Choose real-time or frame-by-frame recording.

3. Set the video frame hold counts.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.8.3.3.1. Select the Recording Source

There are two possible video sources that can be used for recording an animation: **Screen** and **Picture**. The choice of video source depends on what your video hardware/software provides. Here is a description of each:

Screen
can be used if your computer's video hardware can send all or a portion of the computer screen as a video signal to the VTR using a scan converter and associated software. With this option, you are responsible for setting up the scan converter and sending the video signal to the VTR.

Picture
instructs ANSYS Fluent to create a picture of each frame of animation and send the picture file to the computer's video hardware using a system command. This option assumes that your computer's video system includes a frame buffer that can store an image and send it as a video signal to the video recording system.

When using the picture option, a shell script will be called that will send the picture file to the video frame buffer. The default setting is `videocmd`, which is a shell script that is included in your ANSYS Fluent distribution. It is located in *path* `/ansys_inc/v181/fluent/bin`, where *path* is the folder in which you have placed the release folder. This shell script will execute your system's command to send an image file to the video frame buffer. The script `videocmd` is set up to call the SGI system command `memtovid`. If you have a different system, you must copy the shell script `videocmd` to a new file and modify it to perform the proper task on your system (see the comments in `videocmd` for details). You can specify the name of your shell script using the **Video Command** text entry in the Animation Recording Options Dialog Box (p. 2668).

In order to send a picture file of the proper format to the video frame buffer, you must set up the picture format using the Save Picture Dialog Box (p. 2568), which can be displayed by clicking the **Picture Options...** button in the Animation Recording Options Dialog Box (p. 2668). If you choose to perform a window dump to create the picture file, the default window dump command used will also be `videocmd`. You can change this setting to use your own command. After setting the picture options, click **Apply** instead of **Save...** in the Save Picture Dialog Box (p. 2568) to apply the change.

Once you have set up the picture format and system command, you can test the configuration by sending the picture in the current graphics window to the video frame buffer. This is done by clicking on **Preview** in the Animation Recording Options Dialog Box (p. 2668). Note that this is another way to send a black video signal to your VTR when you are preblacking a tape.

31.8.3.3.2. Choose Real-Time or Frame-By-Frame Recording

There are two methods for recording an animation: real-time and frame-by-frame.

Real-Time
can be used if the animation playback speed is fast enough to provide a reasonably smooth animation in real-time. This is only available if the selected record source is **Screen**. In this mode, ANSYS Fluent will simply turn VTR recording on, play the animation, then stop the recording.

Frame-By-Frame
is used to produce a higher-quality video animation by recording one frame at a time. For each animation frame, this method will 1) play the frame on the screen (and generate the picture file, if needed), 2) preroll the VTR, and 3) record the frame. If the animation has 50 frames, this procedure is repeated 50 times, that is, 50 record passes are made. This is the recommended method, because the real-time playback of the animation will usually be too slow and choppy.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When recording in frame-by-frame mode, there is an optional setting called **Frames/Pass**, which can be used to try and speed up the frame-by-frame recording process. It specifies the number of animation frames recorded to tape per record pass. If the animation is long enough (200 frames or more), you can try setting this value to 2 or higher. For example, if you set this value to 2 for a 202-frame animation, it will record animation frame 1 during the first pass, frames 2 and 102 during the second pass, frames 3 and 103 during the third pass, and so on. This is possible only if the animation frames can be rendered in time to be inserted onto the tape during a record pass, so use this setting with caution.

31.8.3.3.3. Set the Video Frame Hold Counts

The video standard NTSC has a frame rate of 30 frames/sec (and the PAL standard has a rate of 25 frames/sec). At the NTSC rate, a 150-frame animation will take only 5 seconds to play. To stretch out the animation, you can record the same animation frame over 2 or more video frames. This is done by setting video frame hold counts for the beginning, middle, and end of the animation, using the Animation Recording Options Dialog Box (p. 2668) controls.

Begin Hold
specifies the number of video frames to hold the first animation frame. It helps to hold the first frame for about 5 seconds (150 video frames for NTSC, or 125 for PAL) so that the viewer can get accustomed to the picture before the animation begins.

Frame Hold
specifies the number of video frames to hold each animation frame, other than the first and last. To slow down your recorded animation, try setting this value to 2 or 3.

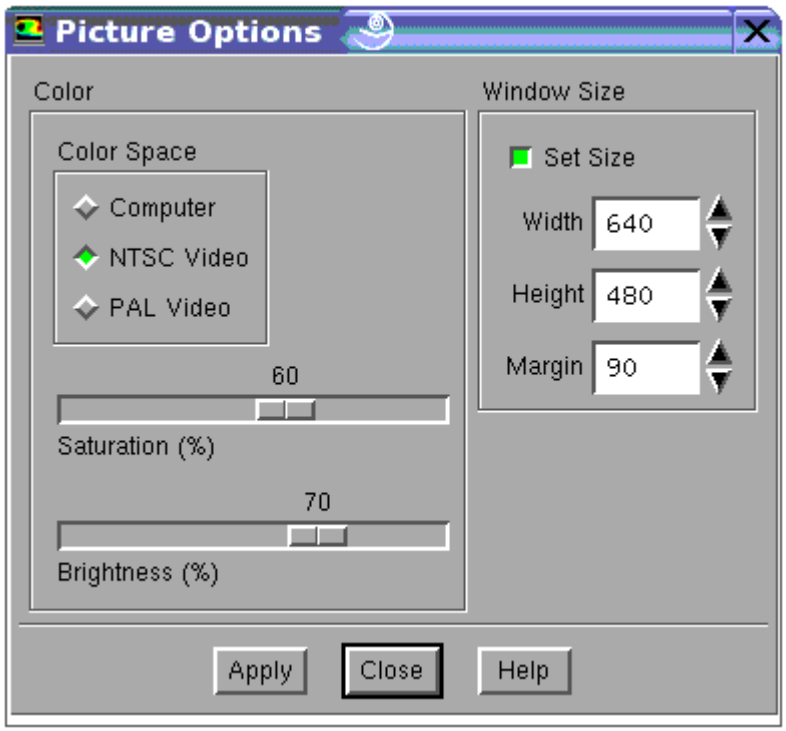
End Hold
specifies the number of video frames to hold the last animation frame. You may want to hold the last animation frame for about 5 seconds to provide closure.

31.8.3.4. Check the Picture Quality

As described in Recording Animations To Video (p. 1830), there are several sacrifices made when sending a computer image to video, including loss of color and resolution. Some steps can be taken to minimize the problem using the Picture Options Dialog Box (p. 2776) (Figure 31.64: The Picture Options Dialog Box (p. 1837)). Display this dialog box by clicking the **Picture...** button in the Video Control Dialog Box (p. 2833).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.64: The Picture Options Dialog Box



Color

Use these controls to ensure that all colors fall into the proper color space for your video device. Also, for best results, set the saturation and brightness levels to 80% or less.

Window Size

If you have a scan converter that converts a portion of the computer screen, you can set the graphics window to a particular pixel size to match the scan converter's window size. You can also create a margin around the picture in the window to keep unwanted parts of the screen (such as the window border) out of the video image.

31.8.3.5. Make Sure Your Tape is Formatted (Preblacked)

Before you can start the recording session, you need to make sure the tape has been preblacked with a time code or frame code. When you start with a brand new tape, you need to take time out and preblack the whole tape first. This can be done using the following procedure:

1. Rewind the tape to the beginning.
2. Select a preblack recording session by selecting **Preblack** in the **Record Session** group box of the Video Control Dialog Box (p. 2833).
3. Send the VTR a black video signal using a scan converter or a picture by clicking the **Preview** button in the Animation Recording Options Dialog Box (p. 2668).
4. Click **Preblack** in the **VTR Controls** section of the Video Control Dialog Box (p. 2833) to start the preblacking.

31.8.3.6. Start the Recording Session

Make sure you have the proper recording session selected. If you are recording an animation, **Animation** should be selected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To start recording onto tape, you must first go to the "in point" on tape where you want the recording to begin. With a blank tape, it is important to start at about 20 seconds into the tape, so the VTR has a chance to preroll up to the in point. You can use the VTR button controls to position the tape, but an easier way to go to a certain point is to type the time code or frame code in the **Time** or **Frame** counter and press **Enter**. For example, a time code of `00:02:36:07` is 2 minutes, 36 seconds, and 7 frames. In order to go to this position on the tape, you can enter the time code as `2:36:07`, leaving out the leading zeros, or you can simply enter `23607`, leaving out the leading zeros and colons.

Once your tape is at the start position for your recording session, click **Record** to start recording.

31.9. Histogram and XY Plots

In addition to the many graphics tools already discussed, ANSYS Fluent also provides tools that enable you to generate XY plots and histograms of solution, file, profile, and residual data. You can modify the colors, titles, legend, and axis and curve attributes to customize your plots. The following sections describe the XY and histogram plotting features in ANSYS Fluent.

31.9.1. Plot Types
31.9.2. XY Plots of Solution Data
31.9.3. XY Plots of File Data
31.9.4. XY Plots of Profiles
31.9.5. XY Plots of Circumferential Averages
31.9.6. XY Plot File Format
31.9.7. Residual Plots
31.9.8. Histograms
31.9.9. Modifying Axis Attributes
31.9.10. Modifying Curve Attributes

31.9.1. Plot Types

Data can be plotted in XY (abscissa/ordinate) form or histogram form. Each form is described below.

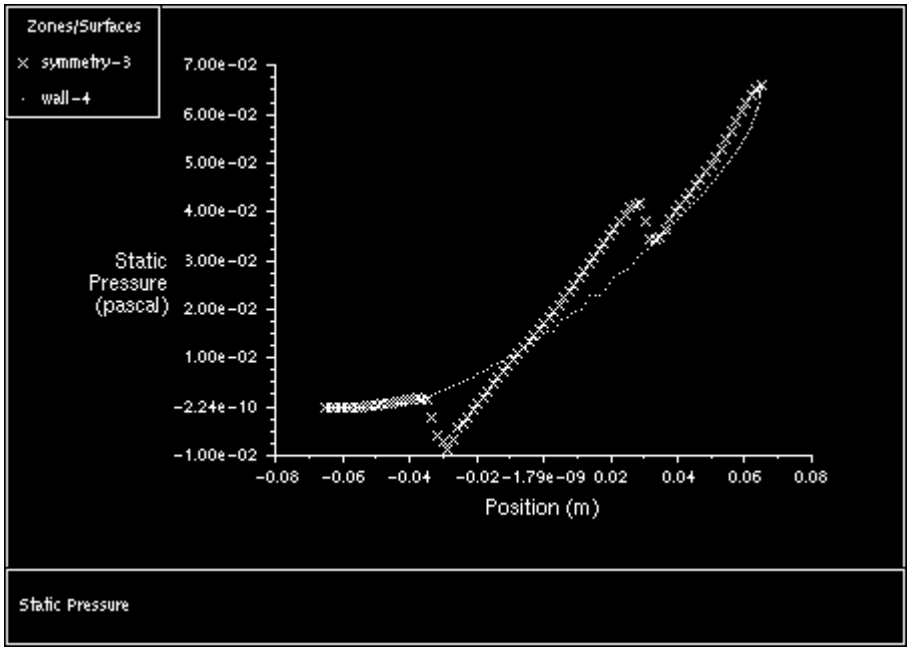
31.9.1.1. XY Plots

An XY (abscissa/ordinate) plot is a line and/or symbol chart of data. Virtually any defined variable or function is accessible for this type of plot. Furthermore, you may read in an externally-generated data file in order to compare your results with experimental data. You can also use the XY-plot facility to plot out profile data, the residual histories of variables, or the time histories if you have a transient problem.

ANSYS Fluent provides tools for controlling many aspects of the XY plot, including background color, legend, and axis and curve attributes. Figure 31.65: Sample XY Plot (p. 1839) shows a sample XY plot.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.65: Sample XY Plot



To differentiate the data being displayed, you can customize the pattern, color and weight of the data lines and the shape, color, and size of the data markers.

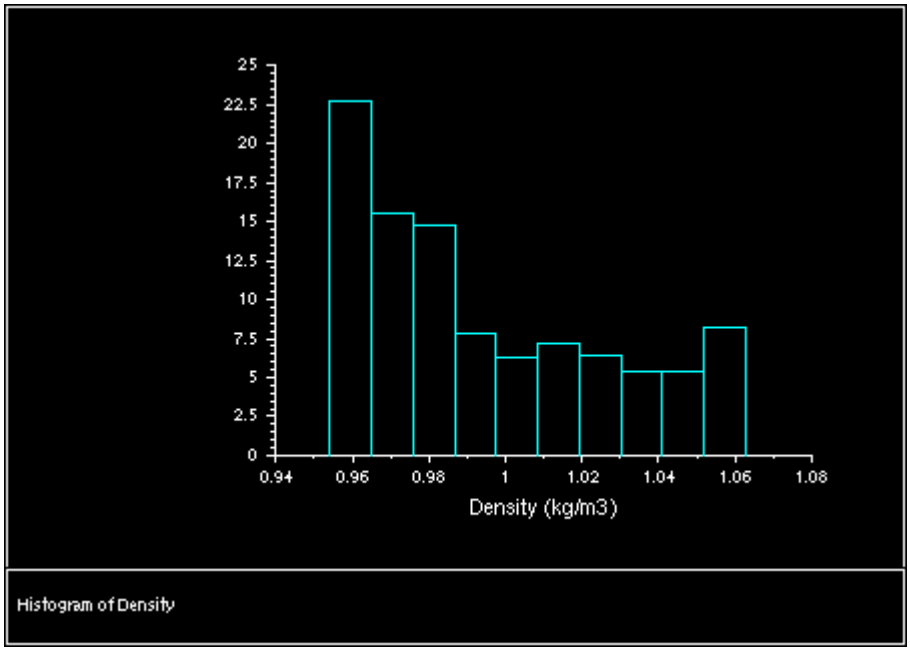
When an XY plot is displayed in the graphics window, you can use the **mouse-probe** option, but all other functions are inactive for XY plots. In addition, you can use any of the mouse buttons to move and resize the legend box.

31.9.1.2. Histograms

A histogram plot is a bar chart of data. It is a representation of a frequency of distribution by means of rectangles of widths representing class intervals and with areas proportional to the corresponding frequencies. When a histogram plot is displayed in the graphics window, you can use the **mouse-probe**, but all other functions are inactive for histogram plots. Figure 31.66: Sample Histogram (p. 1840) shows a sample histogram.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.66: Sample Histogram



See Histogram Reports (p. 1924) for information about printing histogram reports. For more information on histogram plots, see Histograms (p. 1851).

31.9.2. XY Plots of Solution Data

You can produce a very sophisticated XY plot by using data from several zones, surfaces, or files and modifying the axis and curve attributes. Using the capability for loading external data files, you can create plots that compare your ANSYS Fluent results with data from other sources. To get further information about the solution, you can investigate the frequency of distribution of the data using a histogram (see Histograms (p. 1851)).

31.9.2.1. Steps for Generating Solution XY Plots

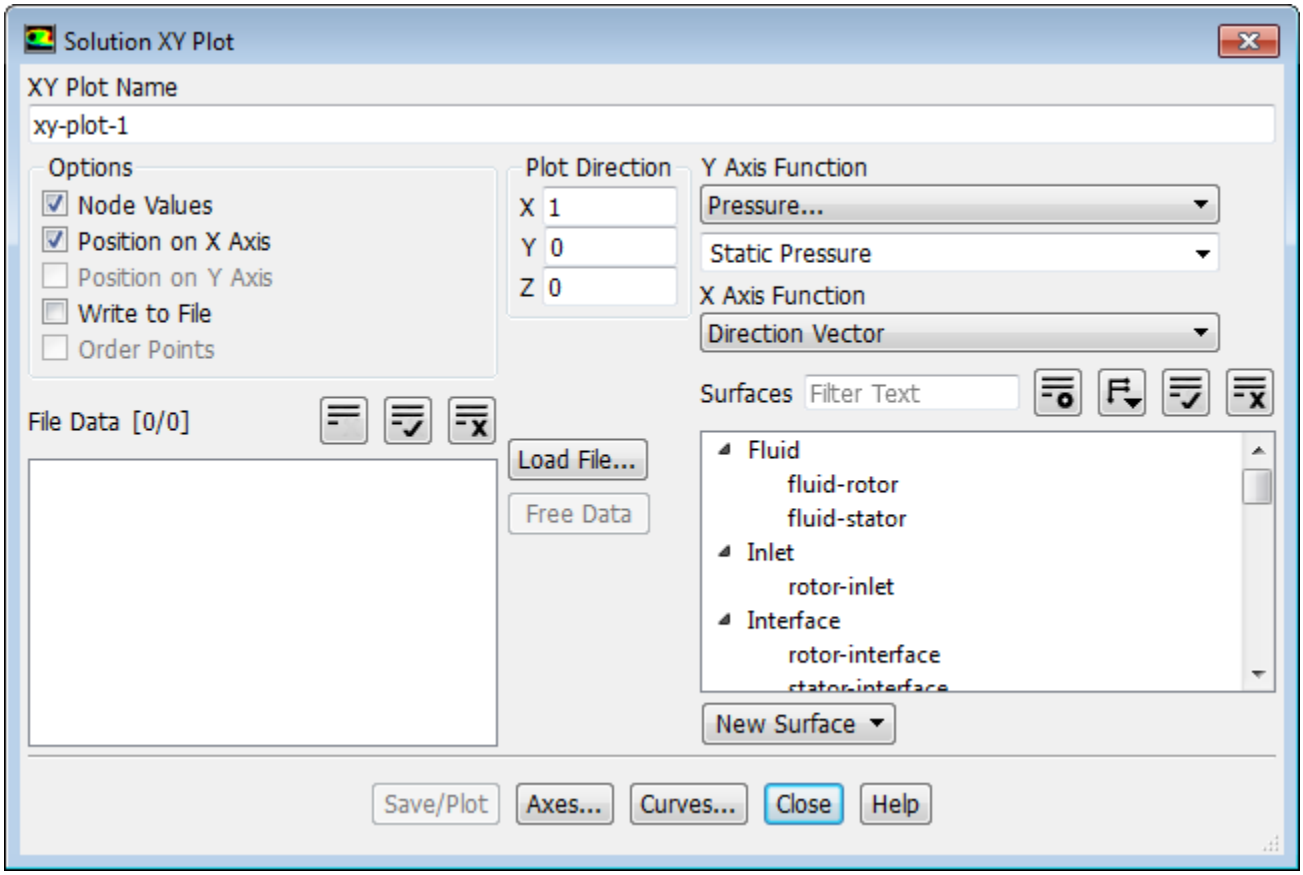
You can create an XY plot of solution data using the Solution XY Plot Dialog Box (p. 2595) (Figure 31.67: The Solution XY Plot Dialog Box (p. 1841)).

Named XY plot definitions can be saved for later use. See Creating and Using Contour Plot Definitions (p. 1762) for additional information on graphics object definitions.

Results → Plots → XY Plot New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.67: The Solution XY Plot Dialog Box



The basic steps for generating a solution XY plot are as follows:

1. Specify the variable(s) you are plotting:

   - To plot a variable on the *y*-axis as a function of position on the *x*-axis, enable the **Position on X Axis** option and choose the variable to be plotted on the *y*-axis in the **Y Axis Function** drop-down list. Select a category from the upper list and then choose the desired quantity in the lower list. For an explanation of the variables in the list, see Field Function Definitions (p. 1931).

   - To plot a variable on the *x*-axis as a function of position on the *y*-axis, enable the **Position on Y Axis** option and choose the variable to be plotted on the *x*-axis in the **X Axis Function** drop-down list.

   - To plot one variable as a function of another, turn off both the **Position on X Axis** and **Position on Y Axis** options and select the variables to be plotted in the **X Axis Function** and **Y Axis Function** drop-down lists.

2. Specify the plot direction:

   - To plot a variable as a function of position along a specified direction vector, select **Direction Vector** in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis), and specify the components of the direction vector for plotting under **Plot Direction**. The position axis of the plot is indicated by the selection of **Position on X Axis** or **Position on Y Axis**. The positions plotted will have coordinate values that correspond to the dot product of the data coordinate vector with the plot direction vector. For example, if you are plotting a variable at the pressure outlet of the geometry shown in Figure 31.68: Geometry Used for XY Plot (p. 1842), you would specify the **Plot Direction** vector (1,0,0)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

since you are interested in how the variable changes as a function of *x*. Figure 31.69: Data Plotted at Outlet Using a Plot Direction of (1,0,0) (p. 1843) shows the resulting XY plot. (If you specified (0,1,0) as the plot direction, all variable values would be plotted at the same position (see Figure 31.70: Data Plotted at Outlet Using a Plot Direction of (0,1,0) (p. 1843)), because the *y* value is the same at every point on the pressure outlet.)

- It is also possible to plot a variable as a function of position along the length of a specified curvilinear surface. The curvilinear surface must be piecewise linear and it cannot contain more than one closed curve, such as a complete circle. To plot a variable in this way, select **Curve Length** in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis). Then specify the plot direction along the surface: to plot the variable along the direction of increasing curve length, select **Default** under **Plot Direction**; to plot the variable in the direction of decreasing surface length, select **Reverse**. To check the direction in which the variable will be plotted along a surface, select the surface in the **Surfaces** list and click **Show** under **Plot Direction**. ANSYS Fluent will display the selected surface in the graphics window, marking the start of the surface with a blue dot and the end of the surface with a red dot. ANSYS Fluent will also display arrows on the surface showing the direction in which the variable will be plotted.

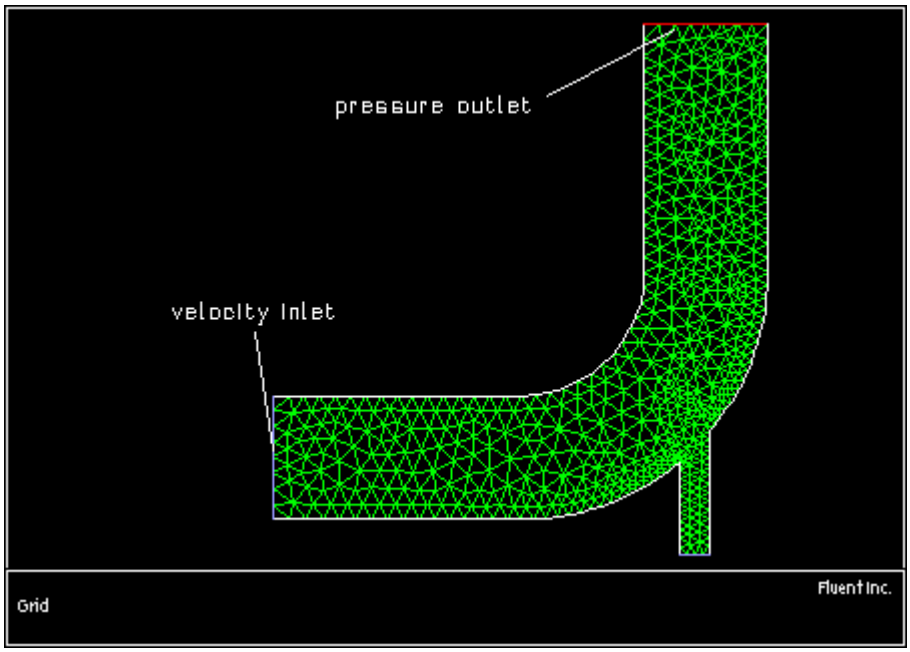
3. Choose the surface(s) on which to plot data in the **Surfaces** list. Note that if you are plotting a variable as a function of position along the length of a curvilinear surface, you can select only one surface in the **Surfaces** list.

4. Set any of the options described below, or modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

5. Click **Plot** to generate the XY plot in the active graphics window.

You can use any of the mouse buttons to annotate the XY plot (see Adding Text to the Graphics Window (p. 1789)) or move the plot legend from its default position in the upper left corner of the graphics window.

Figure 31.68: Geometry Used for XY Plot



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.69: Data Plotted at Outlet Using a Plot Direction of (1,0,0)

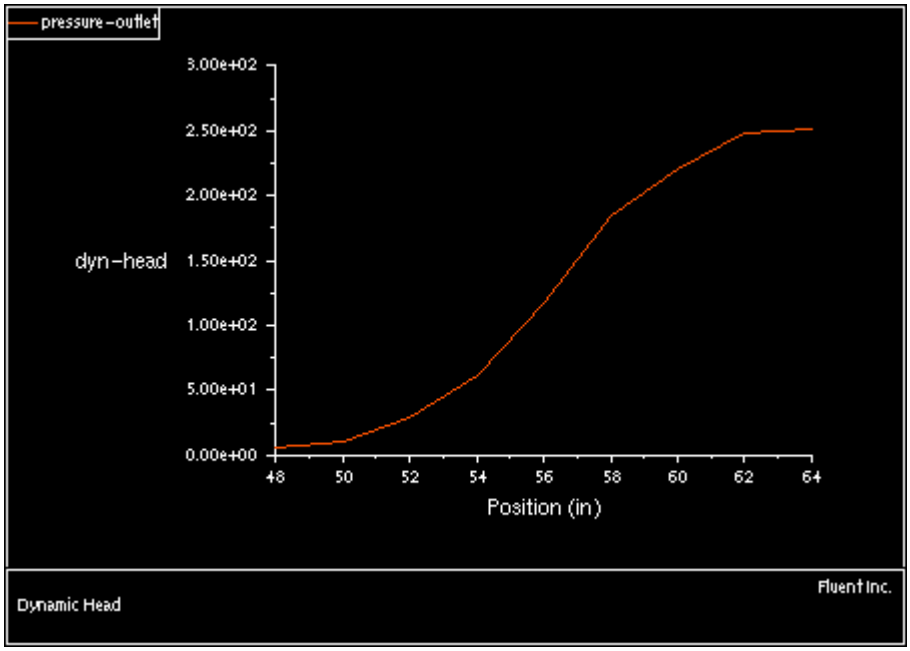


Figure 31.70: Data Plotted at Outlet Using a Plot Direction of (0,1,0)

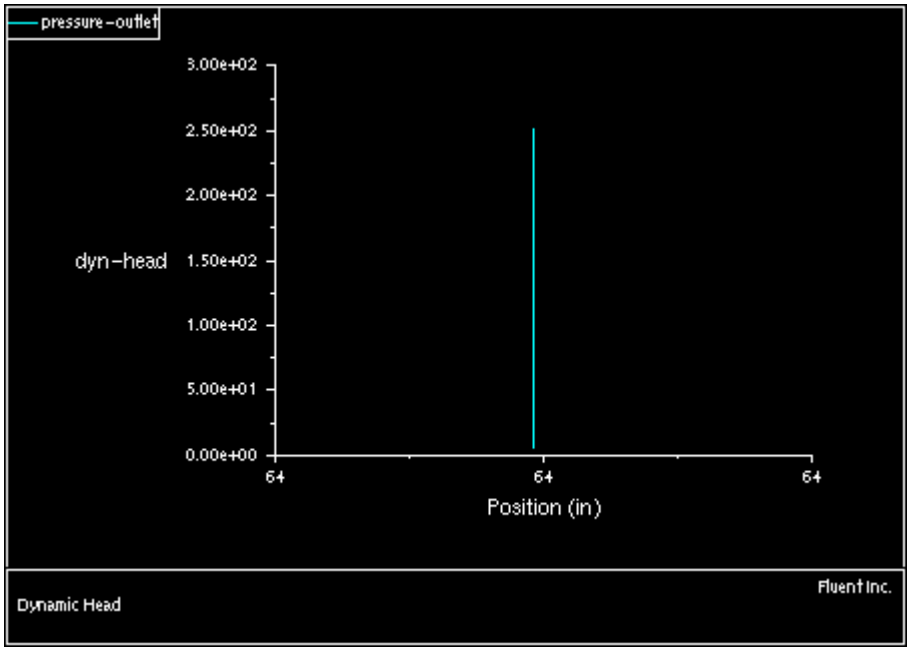


31.9.2.2. Options for Solution XY Plots

The options mentioned in Steps for Generating Solution XY Plots (p. 1840) include the following.

- You can include data from an external file in the solution XY plot to compare your results with experimental data.
- You can also choose node or cell values to be plotted, and save the plot data to a file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.9.2.2.1. Including External Data in the Solution XY Plot

To add external data to your XY plot for comparison with your results, you must first ensure that any external data files are in the format described in XY Plot File Format (p. 1850). You can then load the file(s) by clicking on the **Load File...** button and specifying the file(s) to be read in The Select File Dialog Box (p. 19). Once a file has been loaded, its title will appear in the **File Data** list. You can choose the data file(s) to be included in your plot from the titles in this list.

To remove a file from the **File Data** list, select it and then click **Free Data**.

31.9.2.2.2. Choosing Node or Cell Values

In ANSYS Fluent you can choose to display the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are displayed. If you prefer to display the cell values, turn the **Node Values** option off. Node-averaged data curves may be somewhat smoother than curves for cell values.

For face-only functions (for example, **Wall Shear Stress**), the cell values that are displayed for boundary zone surfaces will actually be the face values. These face values are more accurate, as face-only functions are computed on the faces and not on the cells. For these face-only functions, the cell values on post-processing surfaces will display the values in the cell. For more information about cell values, see Cell Values (p. 1931).

If you are displaying the XY plot to show the effect of a porous medium or 2D fan boundary, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

31.9.2.2.3. Saving the Plot Data to a File

Once you have generated an XY plot, you may want to save the plot data to a file. You can read this file into ANSYS Fluent at a later time and plot it alone using the File XY Plot Dialog Box (p. 2599), as described in XY Plots of File Data (p. 1844), or add it to a plot of solution data, as described above.

To save the plot data to a file, enable the **Write to File** option in the Solution XY Plot Dialog Box (p. 2595). The **Plot** button will change to the **Write...** button. Clicking on the **Write...** button will invoke The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the plot data. The format of this file is described in XY Plot File Format (p. 1850).

To sort the saved plot data in order of ascending *x*-axis value, enable the **Order Points** option in the Solution XY Plot Dialog Box (p. 2595) before you click **Write...**. This option is available only when the **Write to File** option is enabled.

31.9.3. XY Plots of File Data

You can produce XY plots using data contained in external files. The File XY Plot Dialog Box (p. 2599) enables you to display data read from external files in an abscissa/ordinate plot form. The format of the plot file is described in XY Plot File Format (p. 1850).

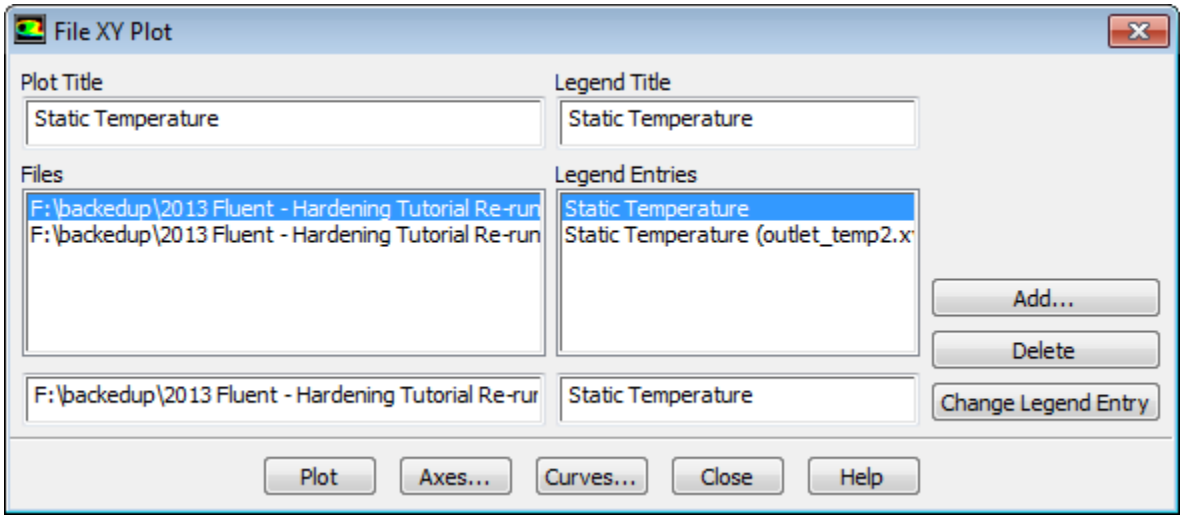
31.9.3.1. Steps for Generating XY Plots of Data in External Files

You can create an XY plot of data contained in one or more external files using the File XY Plot Dialog Box (p. 2599) (Figure 31.71: The File XY Plot Dialog Box (p. 1845)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Results → Plots → File → Set Up...

Figure 31.71: The File XY Plot Dialog Box



The steps for generating a file XY plot are as follows:

1. Load each external data file (with the format described in XY Plot File Format (p. 1850)) by entering its name in the text field beneath the **Files** list and clicking **Add...** (or pressing **Enter**). If you click **Add...** without specifying a name under **Files** (or if you specify an incorrect or duplicate name), The Select File Dialog Box (p. 19) will appear and you can specify one or more files there. When a file is loaded, its name will appear in the **Files** list and its title will appear in the **Legend Entries** list. Data in all loaded files will be plotted, so if you decide not to include one of the loaded files in the plot you must select it and click **Delete**.

2. Set any of the options described below, or modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

3. Click **Plot** to generate an XY plot of the data associated with all loaded files.

31.9.3.2. Options for File XY Plots

The options mentioned in the procedure above include the following. You can change the plot title, legend title, or legend entry.

31.9.3.2.1. Changing the Plot Title

The plot title will appear in the caption box at the bottom of the graphics window. You can modify the plot title by changing the text in **Plot Title** in the File XY Plot Dialog Box (p. 2599) (or by editing the caption box manually, as described in Changing the Legend Display (p. 1788)).

31.9.3.2.2. Changing the Legend Entry

When you plot data from a single file, the y-axis of the plot will be labeled by the "legend entry." To modify this label, click the text in the **Legend Entries** list, edit the text that appears in the text field below the list, and then click **Change Legend Entry** (or press **Enter**). When you next plot the data, the new legend entry will appear in the plot.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.9.3.2.3. Changing the Legend Title

When you plot data from more than one file, a legend will appear in the upper left corner of the graphics window. By default, the legend will have no title. If you want to add a title, enter it in the **Legend Title** text field. The title will appear above the legend the next time you plot the data.

Note that you can use any of the mouse buttons to annotate the plot (see Adding Text to the Graphics Window (p. 1789)) or move the legend from its default position.

31.9.4. XY Plots of Profiles

ANSYS Fluent enables two options for generating XY plots of data related to boundary profiles. Using the Plot Profile Data Dialog Box (p. 2601), you can plot the original data points from the profile file you have read into ANSYS Fluent. Alternatively, you can plot the values assigned to the cell faces on the boundary after the profile file has been interpolated, by using the Plot Interpolated Data Dialog Box (p. 2601).

Important

Note that you must have valid data when trying to use the profile plotting options.

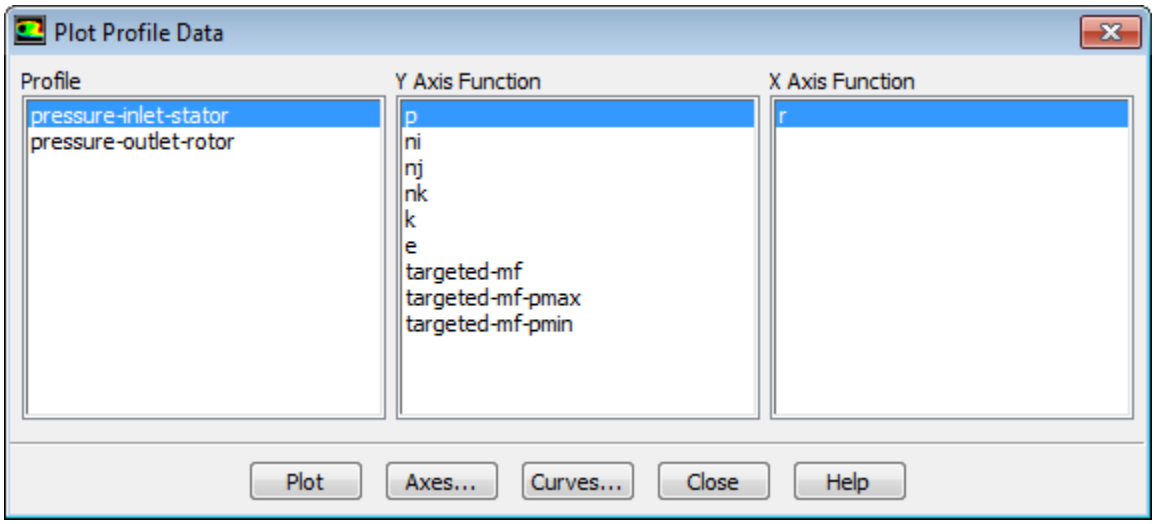
For more information about boundary profiles, see Profiles (p. 435).

31.9.4.1. Steps for Generating Plots of Profile Data

Once you have read a profile file, it is available for plotting by using the Plot Profile Data Dialog Box (p. 2601).

Results → Plots → Profile Data → Set Up...

Figure 31.72: The Plot Profile Data Dialog Box



The procedure for generating an XY plot of the original profile data is as follows:

1. Select one of the profiles you have read from the **Profile** selection list.

2. Select a field of the profile from the **Y Axis Function** selection list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Choose a variable against which you want to plot the field data, and select it from the **X Axis Function** selection list. The available variables will vary depending on the profile, and include **x**, **y**, **z**, **r**, and **time**.

4. Modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

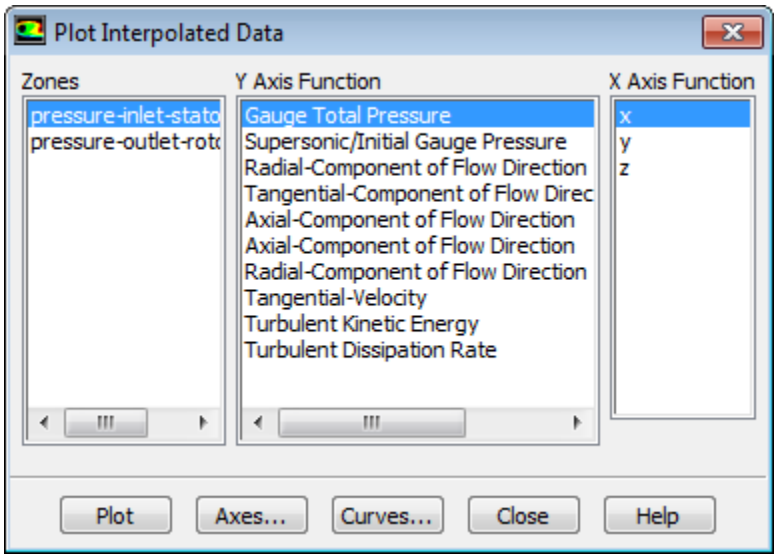
5. Click **Plot** to generate an XY plot of the profile field data.

31.9.4.2. Steps for Generating Plots of Interpolated Profile Data

To interpolate a profile you must first read a profile file for the case, and select a profile field in a boundary conditions dialog box (for example, the Velocity Inlet Dialog Box (p. 2447)). After the flow solution has been initialized, the cell face values of the boundary zone can be plotted by using the Plot Interpolated Data Dialog Box (p. 2601).

Results → Plots → Interpolated Data → Set Up...

Figure 31.73: The Plot Interpolated Data Dialog Box



The procedure for generating an XY plot of the interpolated data is as follows:

1. Select a zone from the **Zones** selection list. Only the zones for which you have set a profile field as one or more of the parameters will be available in this list.

2. Select a profile-related parameter of the zone from the **Y Axis Function** selection list. The name of the parameter will be the same as that of the drop-down list in the boundary condition dialog box from which the profile field was selected.

3. Choose a variable against which you want to plot the field data, and select it from the **X Axis Function** selection list. The available variables are **x**, **y**, and (for 3D cases) **z**.

4. Modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

5. Click **Plot** to generate an XY plot of the cell face values on the boundary.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.9.5. XY Plots of Circumferential Averages

You can also generate a plot of circumferential averages in ANSYS Fluent. This enables you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS Fluent computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate.

31.9.5.1. Steps for Generating an XY Plot of Circumferential Averages

You can generate an XY plot of circumferential averages in the radial direction using the `circum-avg-radial` text command:

`plot` → `circum-avg-radial`

or you can use the `circum-avg-axial` text command to generate an average in the axial direction:

`plot` → `circum-avg-axial`

The procedure for generating an XY plot of circumferential averages is as follows:

1. Specify the variable to be averaged by typing its name when ANSYS Fluent prompts you for `averages of`. You can press **Enter** to see a list of available variables.

2. Choose the surface on which to plot data by typing its name when ANSYS Fluent prompts you for `on surface`.

   Important

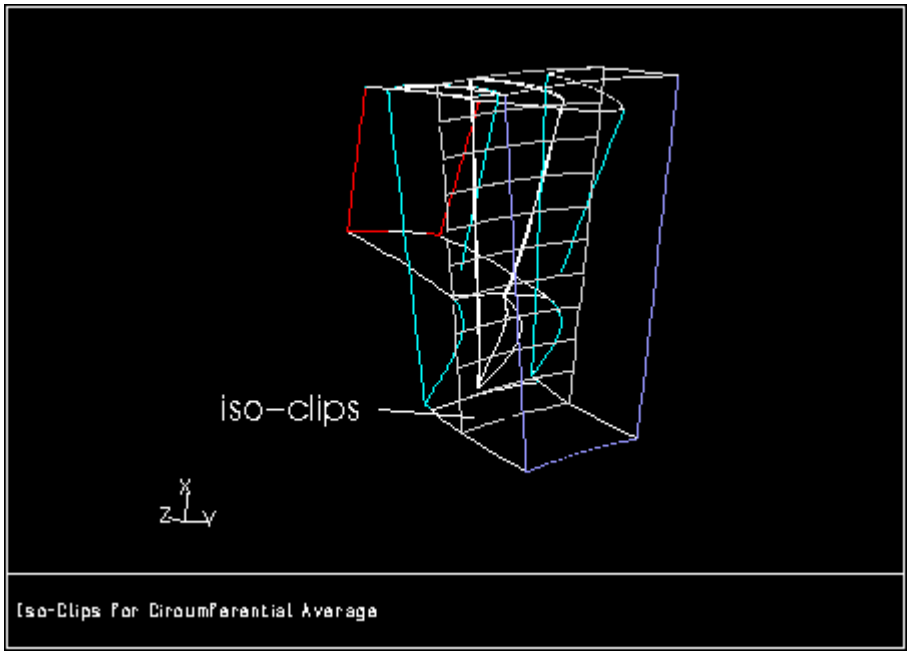
   Use the Mesh Display Dialog Box (p. 2163) to see a list of surfaces on which you can plot data. Pressing **Enter** will not show a list of available surfaces.

3. Specify the `number of bands` to be created. The default number of bands is 5.

   ANSYS Fluent will create circumferential bands by isoclipping the specified surface into equal bands of radial or axial coordinate. An example of the iso-clips created is shown in Figure 31.74: Iso-Clips Created For Circumferential Averaging (p. 1849). The radial or axial coordinate is derived from the rotation axis of the **Reference Zone** specified in the Reference Values Task Page (p. 2502).

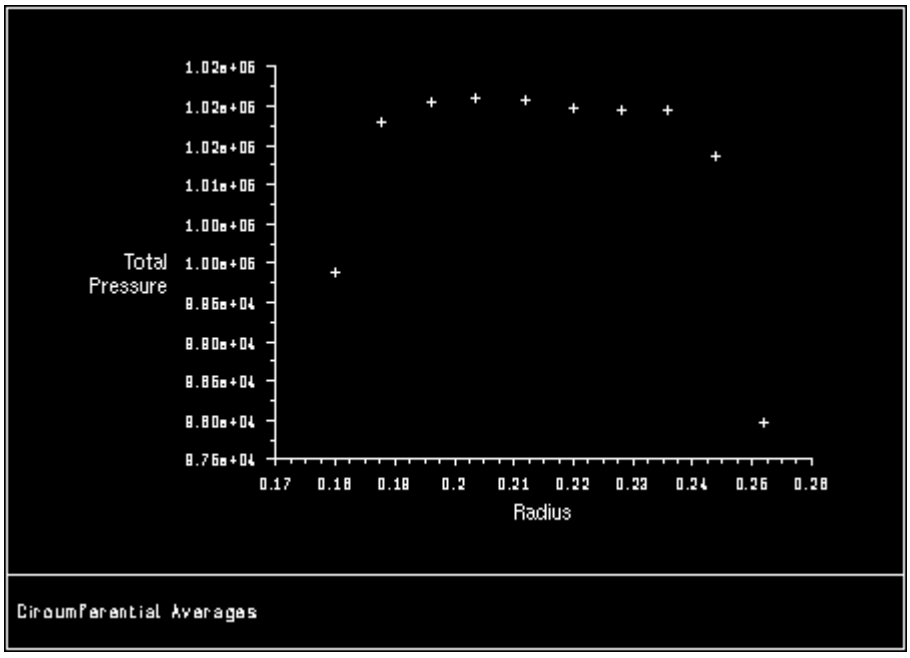
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.74: Iso-Clips Created For Circumferential Averaging



ANSYS Fluent then computes the average of the variable for each band using the area-weighted average described in Computing Surface Integrals of the Theory Guide. Finally, it plots the average of the variable as a function of radial or axial coordinate. Figure 31.75: XY Plot of Circumferential Averages (p. 1849) shows an example of an XY plot of circumferential averages using radial coordinates.

Figure 31.75: XY Plot of Circumferential Averages



When the circumferential average plot is generated, ANSYS Fluent also creates a new surface called `radial-bands` or `axial-bands`, which contains the iso-clips described above (see Figure 31.74: Iso-Clips Created For Circumferential Averaging (p. 1849)). You can use this surface to generate other XY plots. For more information on the creation and manipulation of surfaces, see Creating Surfaces and Cell Registers for Displaying and Reporting Data (p. 1709).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.9.5.2. Customizing the Appearance of the Plot

If you want to customize the appearance of the axes or curves in a circumferential average plot, you can save the plot data to a file (using the `plot-to-file` text command, as described in XY Plot File Format (p. 1850)), read the file into ANSYS Fluent and plot it again (using the File XY Plot Dialog Box (p. 2599), as described in XY Plots of File Data (p. 1844)), and then use the Axes Dialog Box (p. 2608) and Curves Dialog Box (p. 2610) (as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854)) to modify the appearance of the plot.

To save the plot data to a file, first use the `plot-to-file` text command to specify the name of the file.

`plot` → `file-set` → `plot-to-file`

Then generate the circumferential average XY plot as described above. ANSYS Fluent will display the plot in the graphics window, and also save the plot data to the specified file.

31.9.6. XY Plot File Format

The XY file format read or written by ANSYS Fluent includes the following information:

- The title of the plot
- The label for the abscissa and the ordinate
- Cortex variables and pairs of abscissa/ordinate data for each curve in the plot

The following sample file illustrates the XY file format:

```
(title "Velocity Magnitude")
(labels "Position" "Velocity Magnitude")

((xy/key/label "pressure-inlet-8")
  (xy/key/visible? #t)
  (xy/line/pattern "--")
  0.0000 230.097 0.
  0625 160.551
  0.1250 149.205
  ...
  0.5000 183.007
)
```

Similar to the case file format, parentheses bound the various pieces of information in the formatted, ASCII file. The title (`title " "`) and labels (`labels " "`) must be first in the file, then each curve has information in the form (`(cxvar value) x y x y x y...`), where there may be zero or more Cortex variables defined for each curve.

You do not have to include Cortex variables to import your XY data. For example, you may want to import experimental data to compare with the ANSYS Fluent solution. The following example would use the default Cortex variables in the code to define the data. After you import the file into ANSYS Fluent, you could then use the Axes Dialog Box (p. 2608) and the Curves Dialog Box (p. 2610) to customize the XY plot, as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

```
(title "Experiment, Run 11")
(labels "X, m" "Cp")
( 0 1.5
  1.5 1.3
  3.2 1.5
  5.1 1.2
)
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.9.7. Residual Plots

Residual history can be displayed using an XY plot. The abscissa of the plot corresponds to the number of iterations and the ordinate corresponds to the log-scaled residual values.

To plot the current residual history, click **Plot** in the Residual Monitors Dialog Box (p. 2789).

Solution → Monitors → Residuals Edit...

For additional information about using the Residual Monitors Dialog Box (p. 2789) to plot residuals, see Printing and Plotting Residuals (p. 1627).

31.9.8. Histograms

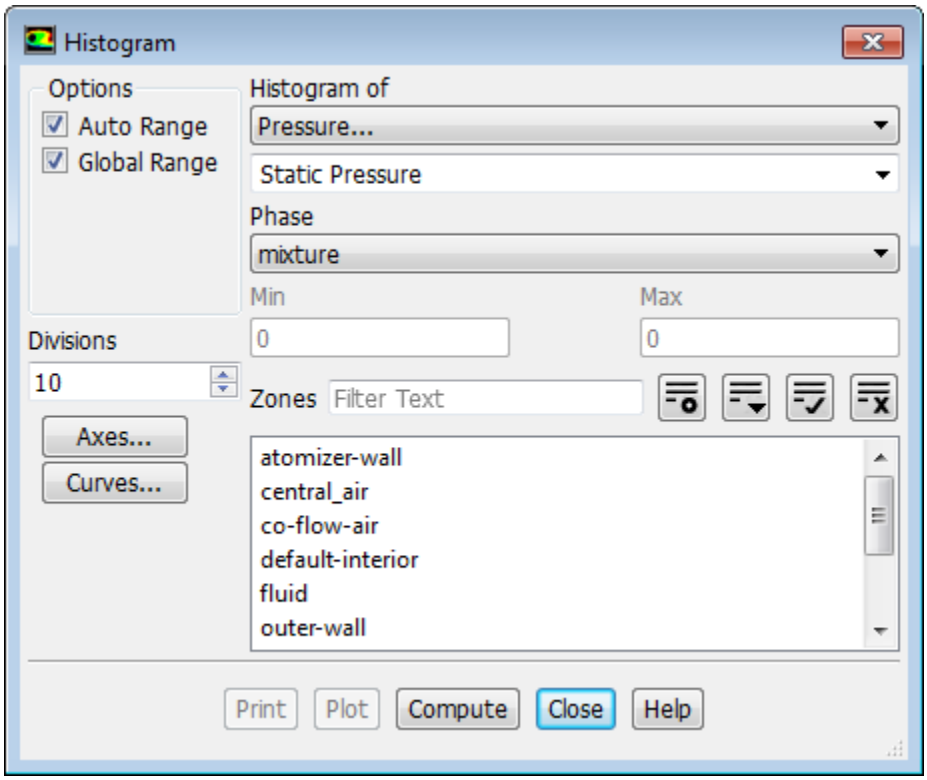
Histograms can be displayed in a graphics window using a bar chart (or printed in the console window, as described in Histogram Reports (p. 1924)). The abscissa of the chart is the desired solution quantity and the ordinate is the percentage of the total number of cells.

31.9.8.1. Steps for Generating Histogram Plots

You can create a histogram plot of solution data using the Histogram Dialog Box (p. 2598) (Figure 31.76: The Histogram Dialog Box (p. 1851)).

Results → Plots → Histogram Edit...

Figure 31.76: The Histogram Dialog Box



The steps for generating a histogram plot are as follows:

1. Choose the scalar quantity to be plotted in the **Histogram Of** drop-down list. Select a category in the upper list and then select the desired quantity in the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

2. Set the number of data intervals that will be plotted in the histogram in the **Divisions** field. By default there will be 10 intervals ("bars") in the histogram plot to finer intervals, increase the number of **Divisions**. You may want to click **Compute** to update the **Min** and **Max** fields when you are trying to decide how many divisions to plot.

3. Select the face or cell zone under **Zones** for which you want results plotted or printed. If all zones are selected, then the entire domain will be plotted. You can also plot histograms based on the selected **Zone Types**.

4. Set the option described below, if desired, or modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

5. Click **Plot** to generate the histogram plot in the active graphics window.

6. Click **Print** to print out your histogram results on individual zones, or the entire domain. Similarly, you can click **Compute** to calculate your histogram results on individual zones, or the entire domain.

31.9.8.2. Options for Histogram Plots

Other than the axis and curve attribute controls mentioned in the procedure above, the only option for histogram plotting is the ability to specify a subrange of values to be plotted.

31.9.8.2.1. Specifying the Range of Values Plotted

By default, the range of values included in the histogram plot is automatically set to the range of values in the entire domain for the selected variable. If you want to focus in on a smaller range of values, you can restrict the range to be displayed.

To manually set the range of values, turn off the **Auto Range** option in the Histogram Dialog Box (p. 2598). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be plotted. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

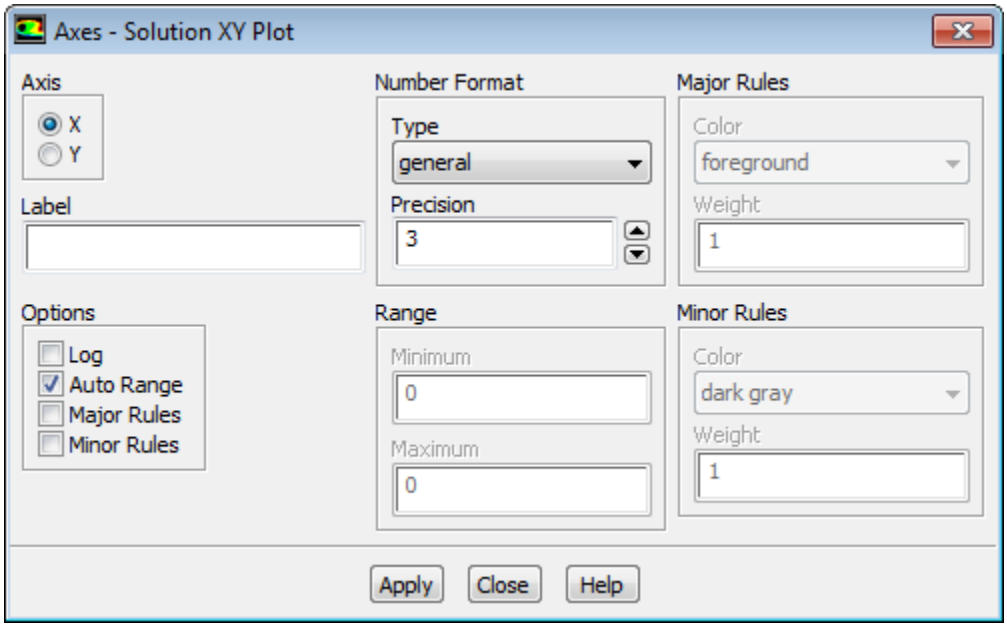
You can also choose to base the minimum and maximum values on the range of values on the selected surfaces, rather than in the entire domain. To do this, turn off the **Global Range** option in the Histogram Dialog Box (p. 2598). The **Min** and **Max** values will be updated when you next click **Compute**.

31.9.9. Modifying Axis Attributes

You can modify the appearance of the XY and parameters that control the labels, scale, range, numbers, and major and minor rules. For each type of plot (solution XY, file XY, profile, residual, histogram, and so on), you can set different axis parameters in the Axes Dialog Box (p. 2608) (Figure 31.77: The Axes Dialog Box (p. 1853)). Note that the title following **Axes** in the dialog box indicates which plot environment you are changing (for example, the **Axes - Solution XY Plot** dialog box controls parameters for solution XY plots).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.77: The Axes Dialog Box



To open the Axes Dialog Box (p. 2608) for a particular plot type, click **Axes...** in the appropriate dialog box (for example, the **Solution XY Plot**, **File XY Plot**, **Plot Profile Data**, **Plot Interpolated Data**, or **Residual Monitors** dialog box).

31.9.9.1. Using the Axes Dialog Box

The Axes Dialog Box (p. 2608) enables you to independently control the characteristics of the ordinate (*y*-axis) and abscissa (*x*-axis) on an XY plot or parameters for one axis or the other, by following the procedure below:

1. Choose the axis for which you want to modify the attributes by selecting **X** or **Y** under **Axis**.
2. Set the desired parameters.
3. Click **Apply** and then choose the other axis and repeat the steps, if desired.

The changes to the axis attributes will appear in the graphics window the next time you generate a plot.

31.9.9.1.1. Changing the Axis Label

If you want to modify the label for the axis, you can do so by editing the **Label** text field in the Axes Dialog Box (p. 2608).

31.9.9.1.2. Changing the Format of the Data Labels

You can change the format of the labels that define the primary data divisions on the axes using the controls under the **Number Format** heading in the Axes Dialog Box (p. 2608).

- To display the real value with an integral and fractional part (for example, 1.0000), select **float** in the **Type** drop-down list. You can set the number of digits in the fractional part by changing the value of **Precision**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To display the real value with a mantissa and exponent (for example, 1.0e-02), select **exponential** in the **Type** drop-down list. You can define the number of digits in the fractional part of the mantissa in the **Precision** field.

- To display the real value with either float or exponential form, depending on the size of the number and the defined **Precision**, choose **general** in the **Type** drop-down list.

31.9.9.1.3. Choosing Logarithmic or Decimal Scaling

By default, decimal scaling is used for both axes (except for the y-axis in residual plots, which uses a log scale). If you want to change to a logarithmic scale, enable the **Log** option in the Axes Dialog Box (p. 2608). To return to a decimal scale, turn off the **Log** option. Note that when you are using the logarithmic scale, the **Range** values are the exponents; to specify a logarithmic range from 1 to 10000, for example, you will specify a minimum value of 1 and a maximum value of 4.

31.9.9.1.4. Resetting the Range of the Axis

By default, the extents of the axis will range from the minimum value plotted to the maximum value plotted. If you want to change the range or extents of the axis, you can do so by turning off the **Auto Range** option in the Axes Dialog Box (p. 2608) and setting the new **Minimum** and **Maximum** values for the **Range**. This feature is useful when you are generating a series of plots and you want the extents of one or both of the axes to be the same, even if the range of plotted values differs. For example, if you are generating plots of temperature on several different wall zones, you might want the minimum and maximum temperature on the y-axis to be the same in every plot so that you can easily compare one plot with another. You would determine a temperature range that includes the temperatures on all walls, and use that as the range for the y-axis in each plot.

31.9.9.1.5. Controlling the Major and Minor Rules

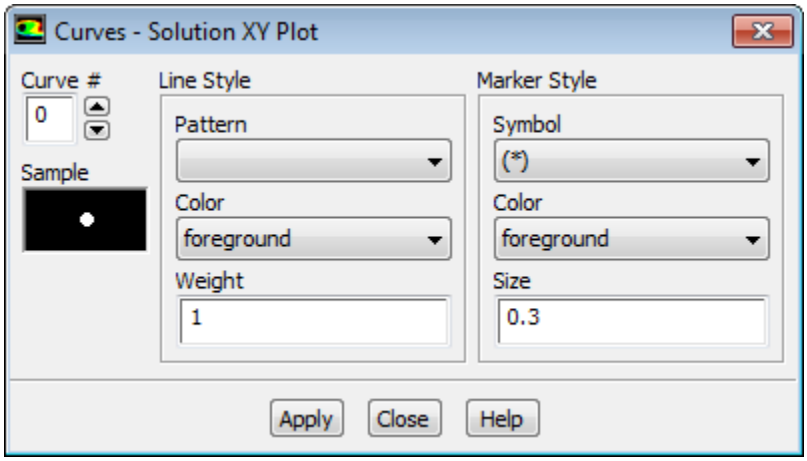
ANSYS Fluent enables you to display major and/or minor rules on the axes. Major and minor rules are the horizontal or vertical lines that mark, respectively, the primary and secondary data divisions and span the whole plot window to produce a "mesh." To add major or minor rules to the plot, enable the **Major Rules** or **Minor Rules** option. You can then specify a color and weight for each type of rule. Under the **Major Rules** or **Minor Rules** heading, select the desired color for the lines in the **Color** drop-down list and specify the line thickness in the **Weight** field. A line of weight 1.0 is normally 1 pixel wide. A weight of 2.0 would make the line twice as thick (that is, 2 pixels wide).

31.9.10. Modifying Curve Attributes

The data curves in XY plots and histograms can be represented by any combination of lines and markers. You can modify the attributes of the curves, including the patterns, weights, and colors of the lines, and the symbols, sizes, and colors of the markers. For each type of plot (solution XY, file XY, profile, residual, parameters in the Curves Dialog Box (p. 2610) (Figure 31.78: The Curves Dialog Box (p. 1855)). Note that the title following **Curves** in the dialog box indicates which plot environment you are changing (for example, the **Curves - Solution XY Plot** dialog box controls curve parameters for solution XY plots).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.78: The Curves Dialog Box



To open the Curves Dialog Box (p. 2610) for a particular plot type, click **Curves...** in the appropriate dialog box (for example, **Solution XY Plot**, **File XY Plot**, **Plot Profile Data**, **Plot Interpolated Data**, or **Residual Monitors** dialog box).

31.9.10.1. Using the Curves Dialog Box

The Curves Dialog Box (p. 2610) enables you to independently control the characteristics of each data curve in an XY plot or parameters for a curve, you will follow the procedure below:

1. Specify the curve for which you want to modify the attributes by increasing or decreasing the **Curve #** counter. The curves are numbered sequentially, starting from 0. For example, if you were plotting flow-field values on two surfaces, the first surface would be curve 0, and the second, curve 1. If the plot contains only one curve, the **Curve #** is set to 0 and is not editable.

2. Set the desired line and/or marker parameters as described below.

3. Click **Apply** and then choose another **Curve #** and repeat the steps, if desired.

Your changes to the curve attributes will appear in the graphics window the next time you generate a plot.

31.9.10.1.1. Changing the Line Style

You can control the pattern, color, and weight of the line using the controls under the **Line Style** heading:

- To set the line pattern for the curve, choose one of the items in the **Pattern** drop-down list. Except for **center** and **phantom** lines, the list displays examples of the pattern choices. A **center** line alternates a very long dash and a short dash and a **phantom** line alternates a very long dash and a double short dash. Note that selecting the second item in the drop-down list, represented by 4 short dashes, will result in a solid-line curve.

> **Important**
>
> If you do not want the data points to be connected by any type of line (that is, if you plan to use just markers), select the "blank" choice, which is the first item in the **Pattern** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To set the color of the line, pick one of the choices in the **Color** drop-down list.
- To define the line thickness, set the value of **Weight**. A line weight of 1.0 is normally 1 pixel wide. Therefore, a weight of 2.0 would make the line twice as thick (that is, 2 pixels wide).

31.9.10.1.2. Changing the Marker Style

You can control the symbol, color, and size for the data marker using the controls under the **Marker Style** heading:

- To set the symbol used to mark data, choose one of the items in the **Symbol** drop-down list. The list displays examples of the symbol choices. For example, in plotting pressure-coefficient data on the upper and lower surfaces of an airfoil, the symbol /*\ (filled-in upward-pointing triangle) could be used for the marker representing the upper surface data, and the symbol */ (filled-in downward-pointing triangle) could be used for the marker representing the lower surface data.

  Important

  If you do not want the data points to be represented by markers (that is, if you plan to use just a line connecting the data points), select the "blank" choice, which is the first item in the **Style** list.

- To set the color of the marker, pick one of the choices in the **Color** drop-down list.
- To define the size of the data marker, set the value of **Size**. A symbol of size 1.0 is 3.0% of the height of the display screen, except for the "." symbol, which is always one pixel.

31.9.10.1.3. Previewing the Curve Style

To see what a particular setting will look like in the plot, you can preview it in the **Sample** window of the Curves Dialog Box (p. 2610). A single marker and/or line will be shown with the specified style attributes.

31.10. Turbomachinery Postprocessing

In addition to the many graphics tools already discussed, ANSYS Fluent also provides turbomachinery-specific postprocessing features that can be accessed once you have defined the topology of the problem. Information on postprocessing for turbomachinery applications is provided in the following sections:

31.10.1. Defining the Turbomachinery Topology
31.10.2. Generating Reports of Turbomachinery Data
31.10.3. Displaying Turbomachinery Averaged Contours
31.10.4. Displaying Turbomachinery 2D Contours
31.10.5. Generating Averaged XY Plots of Turbomachinery Solution Data
31.10.6. Globally Setting the Turbomachinery Topology
31.10.7. Turbomachinery-Specific Variables

31.10.1. Defining the Turbomachinery Topology

In order to establish the turbomachinery-specific coordinate system used in subsequent postprocessing functions, ANSYS Fluent requires you to define the topology of the flow domain. The procedure for defining the topology is described further in this section, along with details about the boundary types.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The current implementation of the turbomachinery topology definition for postprocessing is no longer limited to one row of blades at a time. If your geometry contains multiple rows of blades, you can define all turbomachinery topologies simultaneously. You can name and/or manage all topologies and perform various turbomachinery postprocessing tasks on a single topology or on all topologies at once.

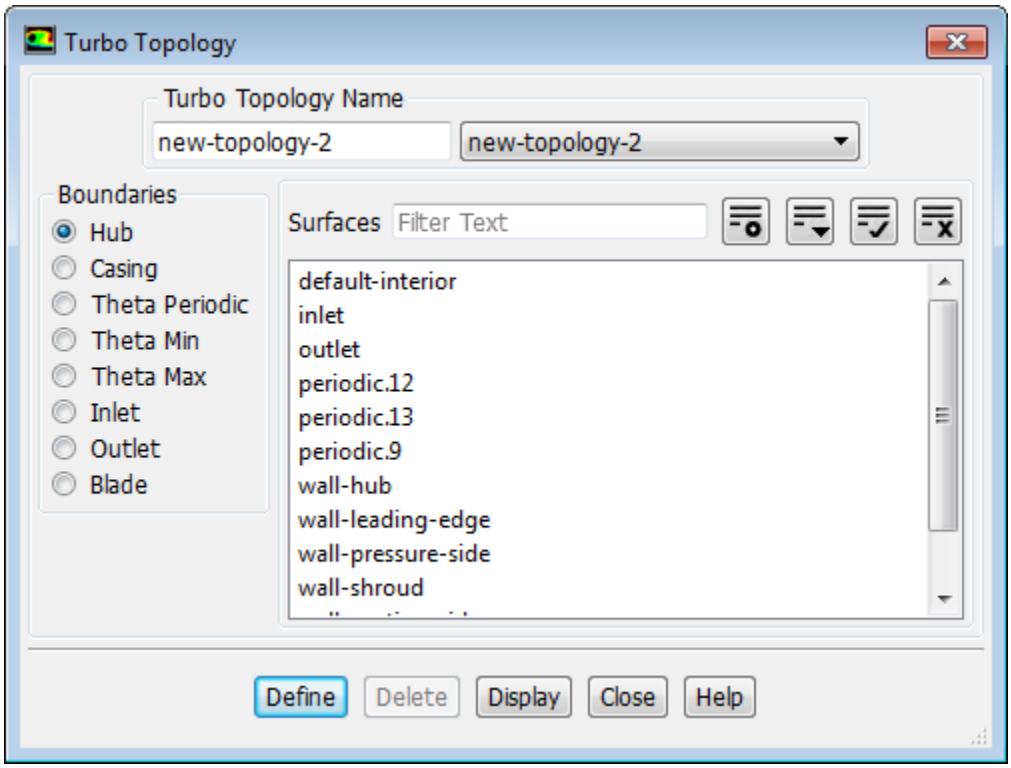
Important

The turbo coordinates can only be generated properly if the correct rotation axis is specified in the boundary conditions dialog box for the fluid zone (see Specifying the Rotation Axis (p. 255)).

To define the turbomachinery topology in ANSYS Fluent, you will use the Turbo Topology Dialog Box (p. 2822) (Figure 31.79: The Turbo Topology Dialog Box (p. 1857)).

Setting Up Domain → Mesh Models → Turbo Topology...

Figure 31.79: The Turbo Topology Dialog Box



The procedure for defining topology for your turbomachinery application are as follows:

1. Select a boundary type under **Boundaries** (for example, **Hub** in Figure 31.79: The Turbo Topology Dialog Box (p. 1857)). The boundary types are described in detail in Boundary Types (p. 1858).

2. In the **Surfaces** list, choose the surface(s) that represent the boundary type you selected in step 1.

   If you want to select several surfaces of the same type, click and select **Surface Type** under **Group By**, which organizes the surfaces in a tree view that is grouped by surface type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Another shortcut is to use the **Filter Text** entry box to filter the **Surfaces** list to show only the surfaces that match the pattern you enter. For additional information on using the **Filter Text** entry box, see Filter Text Entry Boxes (p. 15).

3. Repeat the steps 1 and 2 for all the boundary types that are relevant for your model.

Important

For a complete turbo topology definition the surfaces defined as inlet, outlet, hub, casing, periodic, theta min, and theta max (if available) should form a closed domain.

4. Enter a name in the **Turbo Topology Name** field or keep the default name.

5. Click **Define** to complete the definition of the boundaries.

   ANSYS Fluent will inform you that the turbomachinery postprocessing functions have been activated.

6. Specify a position vector that is defined as $\theta=0$. This position vector should be outside the domain, for example, if your domain lies in the first and second quadrant, specify negative y-axis as the zero θ line. This will ensure that there is no discontinuity in angular coordinates within the domain. This can be done using the `display/set/zero-angle-dir` command.

   Default zero $\theta=0$ line is $+y$-axis. If this axis passes through the domain, you should define the zero θ line, so as to satisfy above criteria.

7. To view a defined topology, select the topology from the **Turbo Topology Name** drop-down list and click **Display**. The defined topology is shown in the active graphics window. This enables you to visually check the boundaries to ensure that you have defined them correctly.

8. To edit a defined topology, select the topology from the **Turbo Topology Name** drop-down list, make the appropriate changes and click **Modify**.

9. To remove a defined topology, select the topology from the **Turbo Topology Name** drop-down list and click **Delete**.

Important

Note that the topology setup that you define will be saved to the case file when you save the current model. Thus, if you read this case back into ANSYS Fluent, you do not need to set up the topology again.

However, use of a boundary condition file to set the turbo topology for two similar cases may not work properly. In that case you need to set the turbo topology manually.

31.10.1.1. Boundary Types

The boundaries for the turbomachinery topology are as follows (see Figure 31.80: Turbomachinery Boundary Types (p. 1859)):

Hub
is the wall zone(s) forming the lower boundary of the flow passage (generally toward the axis of rotation of the machine).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Casing
is the wall zone(s) forming the upper boundary of the flow passage (away from the axis of rotation of the machine).

Theta Periodic
is the periodic boundary zone(s) on the circumferential boundaries of the flow passage.

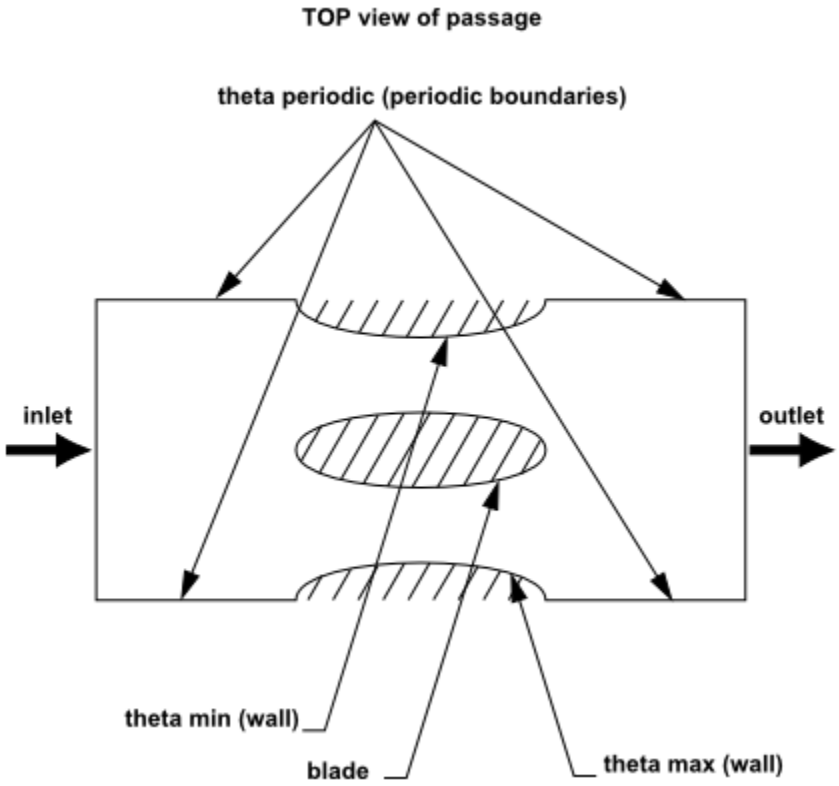
Theta Min
and **Theta Max** are the wall zones at the minimum and maximum angular (θ) positions on a circumferential boundary.

Inlet
is the inlet zone(s) through which the flow enters the passage.

Outlet
is the outlet zone(s) through which the flow exits the passage.

Blade
is the wall zone(s) that defines the blade(s) (if any). Note that these zones cannot be attached to the circumferential boundaries. For this situation, use **Theta Min** and **Theta Max** to define the blade.

Figure 31.80: Turbomachinery Boundary Types



31.10.2. Generating Reports of Turbomachinery Data

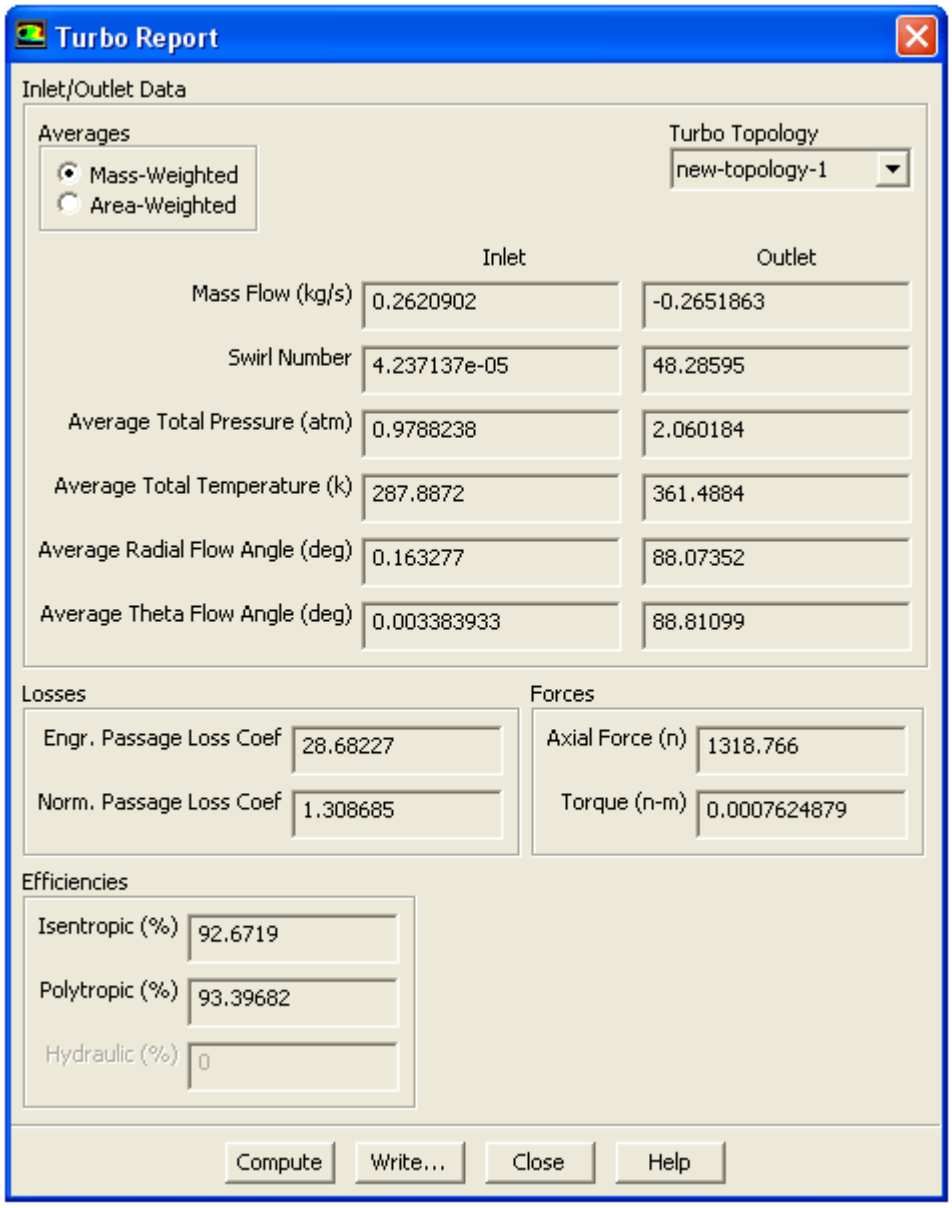
Once you have defined your turbomachinery topologies, as described in Defining the Turbomachinery Topology (p. 1856), you can report a number of turbomachinery quantities, including mass flow, swirl number, torque, and efficiencies.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To report turbomachinery quantities in ANSYS Fluent, you will use the Turbo Report Dialog Box (p. 2819) (Figure 31.81: The Turbo Report Dialog Box (p. 1860)).

Postprocessing → Model Specific → Turbo Topology → Report...

Figure 31.81: The Turbo Report Dialog Box



The procedure for using this dialog box is as follows:

1. Under **Averages**, specify whether you want to report **Mass-Weighted** or **Area-Weighted** averages.
2. Under **Turbo Topology**, specify a predefined turbomachinery topology from the drop-down list.
3. Click **Compute**. ANSYS Fluent will compute the turbomachinery quantities as described below, and display their values.
4. If you want to save the reported values to a file, click **Write...** and specify a name for the file in The Select File Dialog Box (p. 19).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.10.2.1. Computing Turbomachinery Quantities

31.10.2.1.1. Mass Flow

The mass flow rate through a surface is defined as follows:

$$\dot{m}=\int_A (\rho\vec{v}\cdot\hat{n})dA \tag{31.2}$$

where

A = is the area of the inlet or outlet

$\vec{v}$ = the velocity vector

ρ = the fluid density

$\hat{n}$ = a unit vector normal to the surface

31.10.2.1.2. Swirl Number

The swirl number is defined as follows:

$$SW=\frac{\int_S rv_\theta(\vec{v}\cdot\hat{n})\,dS}{\overline{r}\int_S v_z(\vec{v}\cdot\hat{n})\,dS} \tag{31.3}$$

where

r = the radial coordinate (specifically, the radial distance from the axis of rotation)

v_θ = the tangential velocity

$\vec{v}$ = the velocity vector

$\hat{n}$ = a unit vector normal to the surface,

S = the inlet or outlet

$$\overline{r}=\frac{1}{S}\int_S rdS$$

31.10.2.1.3. Average Total Pressure

The area-averaged total pressure is defined as follows:

$$\overline{p}_t=\frac{\int_A p_t dA}{A} \tag{31.4}$$

where p_t is the total pressure and A is the area of the inlet or outlet.

The mass-averaged total pressure is defined as follows:

$$\overline{p}_t=\frac{\int_A \left(\rho p_t|\vec{v}\cdot\hat{n}|\right)dA}{\int_A \left(\rho|\vec{v}\cdot\hat{n}|\right)dA} \tag{31.5}$$

where,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

p_t = the total pressure

A = the area of the inlet or outlet

$\vec{v}$ = the velocity vector

ρ = the fluid density

$\hat{n}$ = a unit vector normal to the surface

31.10.2.1.4. Average Total Temperature

The area-averaged total temperature is defined as follows:

$$\overline{T}_t = \frac{\int_A T_t dA}{A} \tag{31.6}$$

where T_t is the total temperature and A is the area of the inlet or outlet.

The mass-averaged total temperature is defined as follows:

$$\overline{T}_t = \frac{\int_A \left(\rho T_t \left|\vec{v}\cdot\hat{n}\right|\right) dA}{\int_A \left(\rho \left|\vec{v}\cdot\hat{n}\right|\right) dA} \tag{31.7}$$

where,

T_t = the total temperature

A = the area of the inlet or outlet

$\vec{v}$ = the velocity vector

ρ = the fluid density

$\hat{n}$ = a unit vector normal to the surface

31.10.2.1.5. Average Flow Angles

The area-averaged flow angles are defined as follows:

$$\overline{\alpha}_r = \tan^{-1}\left(\frac{\int_A v_\theta dA}{\int_A v_z dA}\right) \tag{31.8}$$

in the radial direction, and

$$\overline{\alpha}_\theta = \tan^{-1}\left(\frac{\int_A v_r dA}{\int_A v_z dA}\right) \tag{31.9}$$

in the tangential direction, where v_z, v_r, and v_θ represent the axial, radial, and tangential velocities, respectively.

The mass-averaged flow angles are defined as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\overline{\alpha}_{r,m} = \tan^{-1}\left(\frac{\int_A (\rho v_r) dA}{\int_A (\rho v_z) dA}\right) \tag{31.10}$$

in the radial direction, and

$$\overline{\alpha}_{\theta,m} = \tan^{-1}\left(\frac{\int_A (\rho v_\theta) dA}{\int_A (\rho v_z) dA}\right) \tag{31.11}$$

in the tangential direction.

31.10.2.1.6. Passage Loss Coefficient

The engineering loss coefficient is defined as follows:

$$K_L = \frac{\overline{p}_{t,i} - \overline{p}_{t,o}}{\frac{1}{2}\rho \overline{v}_i^2} \tag{31.12}$$

where,

$\overline{p}_{t,i}$ = the mass-averaged total pressure at the inlet

$\overline{p}_{t,o}$ = the mass-averaged total pressure at the outlet

ρ = the density of the fluid

$\overline{v}_i$ = the mass-averaged velocity magnitude at the inlet

The normalized loss coefficient is defined as follows:

$$K_{L,n} = \frac{\overline{p}_{t,i} - \overline{p}_{t,o}}{\overline{p}_{t,i} - \overline{p}_{s,o}} \tag{31.13}$$

where $\overline{p}_{s,o}$ is the mass-averaged static pressure at the outlet.

31.10.2.1.7. Axial Force

The axial force on the rotating parts is defined as follows:

$$F_a = \left(\int_S \left(\overline{\overline{\tau}} \cdot \hat{n}\right) dS\right) \cdot \hat{a} \tag{31.14}$$

where,

S = the surfaces comprising all rotating parts

$\overline{\overline{\tau}}$ = the total stress tensor (pressure and viscous stresses)

$\hat{n}$ = a unit vector normal to the surface

$\hat{a}$ = a unit vector parallel to the axis of rotation

31.10.2.1.8. Torque

The torque on the rotating parts is defined as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$T=\left(\int_S \left(\vec{r}\times\left(\bar{\bar{\tau}}\cdot\hat{n}\right)\right) dS\right)\cdot\hat{a} \tag{31.15}$$

where,

S = the surfaces comprising all rotating parts

$\bar{\bar{\tau}}$ = the total stress tensor

$\hat{n}$ = a unit vector normal to the surface

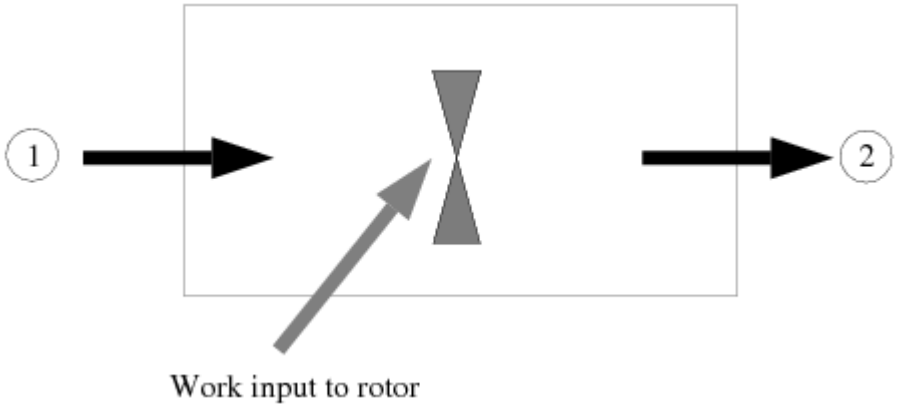
$\vec{r}$ = the position vector

$\hat{a}$ = a unit vector parallel to the axis of rotation

31.10.2.1.9. Efficiencies for Pumps and Compressors

The definitions of the efficiencies for compressible and incompressible flows in pumps and compressors are described in this section. Efficiencies for turbines are described later in this section. Consider a pumping or compression device operating between states 1 and 2 as illustrated in Figure 31.82: Pump or Compressor (p. 1864). Work input to the device is required to achieve a specified compression of the working fluid.

Figure 31.82: Pump or Compressor



Assuming that the processes are steady state, steady flow, and that the mass flow rates are equal at the inlet and outlet of the device (no film cooling, bleed air removal, and so on), the efficiencies for incompressible and compressible flows are as described in the following subsections.

31.10.2.1.9.1. Incompressible Flows

For devices such as liquid pumps and fans (2D boundaries or 3D cell zones) at low speeds, the working fluid can be treated as incompressible. The efficiency of a pumping process with an incompressible working fluid is defined as the ratio of the head rise achieved by the fluid to the power supplied to the rotor/impeller. This can be expressed as follows:

$$\eta=\frac{Q\left(p_{t2}-p_{t1}\right)}{T\omega} \tag{31.16}$$

where,

Q = volumetric flow rate

p_t = total pressure

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

T = net torque acting on the rotor/impeller

ω = rotational speed

This definition is sometimes called the "hydraulic efficiency". Often, other efficiencies are included to account for flow leakage (volumetric efficiency) and mechanical losses along the transmission system between the rotor and the machine providing the power for the rotor/impeller (mechanical efficiency). Incorporating these losses then yields a total efficiency for the system.

31.10.2.1.9.2. Compressible Flows

For gas compressors that operate at high speeds and high pressure ratios, the compressibility of the working fluid must be taken into account. The efficiency of a compression process with a compressible working fluid is defined as the ratio of the work required for an ideal (reversible) compression process to the actual work input. This assumes the compression process occurs between states 1 and 2 *for a given pressure ratio*. In most cases, the pressure ratio is the *total pressure at state 2* divided by the *total pressure at state 1*. If the process is also adiabatic, then the ideal state at 2 is the *isentropic* state.

From the foregoing definition, the efficiency for an adiabatic compression process can be written as

$$\eta_c = \frac{h_{t2,i} - h_{t1}}{h_{t2} - h_{t1}} \tag{31.17}$$

where,

h_{t1} = total enthalpy at 1

h_{t2} = actual total enthalpy at 2

$h_{t2,i}$ = isentropic total enthalpy at 2

If the specific heat is constant, Equation 31.17 (p. 1865) can also be expressed as

$$\eta_c = \frac{T_{t2,i} - T_{t1}}{T_{t2} - T_{t1}} \tag{31.18}$$

where,

T_{t1} = total temperature at 1

T_{t2} = actual total temperature at 2

$T_{t2,i}$ = isentropic total temperature at 2

Using the isentropic relation

$$\frac{T_{t2,i}}{T_{t1}} = \left(\frac{p_{t2}}{p_{t1}}\right)^{\frac{\gamma-1}{\gamma}} \tag{31.19}$$

where γ is the ratio of specific heats specified in the Reference Values Task Page (p. 2502).

The efficiency can be written in the compact form

$$\eta_c = \frac{T_{t1}\left[\left(\frac{p_{t2}}{p_{t1}}\right)^{\frac{\gamma-1}{\gamma}} - 1\right]}{T_{t2} - T_{t1}} \tag{31.20}$$

Note that this definition requires data only for the *actual* states 1 and 2.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

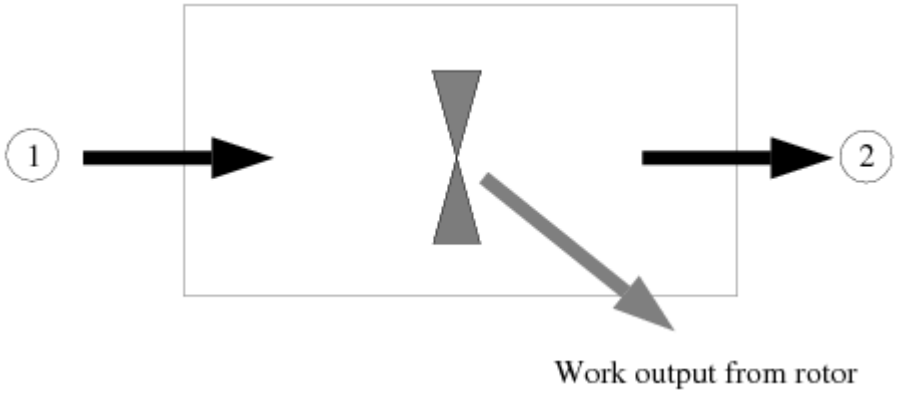
Compressor designers also make use of the polytropic efficiency when comparing one compressor with another. The polytropic efficiency is defined as follows:

$$\eta_{c,p}=\frac{\frac{\gamma-1}{\gamma}\ln\left(\frac{p_{t2}}{p_{t1}}\right)}{\ln\left(\frac{T_{t2}}{T_{t1}}\right)} \tag{31.21}$$

31.10.2.1.10. Efficiencies for Turbines

Consider a turbine operating between states 1 and 2 in Figure 31.83: Turbine (p. 1866). Work is extracted from the working fluid as it expands through the turbine. Assuming that the processes are steady state, steady flow, and that the mass flow rates are equal at the inlet and outlet of the device (no film cooling, bleed air removal, and so on), turbine efficiencies for incompressible and compressible flows are as described below.

Figure 31.83: Turbine



31.10.2.1.10.1. Incompressible Flows

The efficiency of a turbine with an incompressible working fluid is defined as the ratio of the work delivered to the rotor to the energy available from the fluid stream. This ratio can be expressed as follows:

$$\eta=\frac{T\omega}{Q\left(p_{t1}-p_{t2}\right)} \tag{31.22}$$

where,

Q = volumetric flow rate

p_t = total pressure

T = net torque acting on the rotor/impeller

ω = rotational speed

Note the similarity between this definition and the definition of incompressible compression efficiency (Equation 31.16 (p. 1864)). As with hydraulic pumps and compressors, other efficiencies (for example, volumetric and mechanical efficiencies) can be defined to account for other losses in the system.

31.10.2.1.10.2. Compressible Flows

For high-speed gas turbines operating at large expansion pressure ratios, compressibility must be accounted for. The efficiency of an expansion process with a compressible working fluid is defined as the ratio of the actual work extracted from the fluid to the work extracted from an ideal (reversible) process.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This assumes that the expansion process occurs between states 1 and 2 *for a given pressure ratio*. In contrast to the compression process, the pressure ratio for expansion is the *total pressure at state 1* divided by the *total pressure at state 2*. If the process is also adiabatic, then the ideal state at 2 is the *isentropic* state.

From the foregoing definition, the efficiency for an adiabatic expansion process through a turbine can be written as

$$\eta_c = \frac{h_{t1} - h_{t2}}{h_{t1} - h_{t2,i}} \tag{31.23}$$

where

h_{t1} = total enthalpy at 1

h_{t2} = actual total enthalpy at 2

$h_{t2,i}$ = isentropic total enthalpy at 2

If the specific heat is constant, Equation 31.23 (p. 1867) can also be expressed as

$$\eta_e = \frac{T_{t1} - T_{t2}}{T_{t1} - T_{t2,i}} \tag{31.24}$$

where

T_{t1} = total temperature at 1

T_{t2} = actual total temperature at 2

$T_{t2,i}$ = isentropic total temperature at 2

Using the isentropic relation

$$\frac{T_{t1}}{T_{t2,i}} = \left(\frac{p_{t1}}{p_{t2}}\right)^{\frac{\gamma-1}{\gamma}} \tag{31.25}$$

the expansion efficiency can be written in the compact form

$$\eta_e = \frac{T_{t1} - T_{t2}}{T_{t1}\left[1 - \left(\frac{p_{t2}}{p_{t1}}\right)^{\frac{\gamma-1}{\gamma}}\right]} \tag{31.26}$$

Note that this definition requires data only for the *actual* states 1 and 2.

As with compressors, one may also define a polytropic efficiency for turbines. The polytropic efficiency is defined as follows:

$$\eta_{e,p} = \frac{\ln\left(\frac{T_{t1}}{T_{t2}}\right)}{\frac{\gamma-1}{\gamma}\ln\left(\frac{p_{t1}}{p_{t2}}\right)} \tag{31.27}$$

31.10.3. Displaying Turbomachinery Averaged Contours

Turbo averaged contours are generated as projections of the values of a variable averaged in the circumferential direction and visualized on an r- z plane. A sample plot is shown in Figure 31.85: Turbo Averaged Filled Contours of Static Pressure (p. 1869).

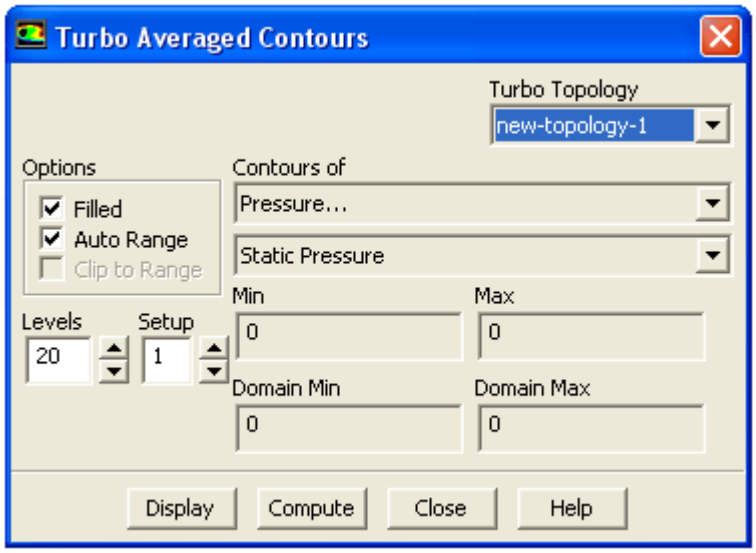
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.10.3.1. Steps for Generating Turbomachinery Averaged Contour Plots

You can display contours using the Turbo Averaged Contours Dialog Box (p. 2816) (Figure 31.84: The Turbo Averaged Contours Dialog Box (p. 1868)).

Postprocessing → Model Specific → Turbo Topology → Averaged Contours...

Figure 31.84: The Turbo Averaged Contours Dialog Box



The basic steps for generating a turbo averaged contour plot are as follows:

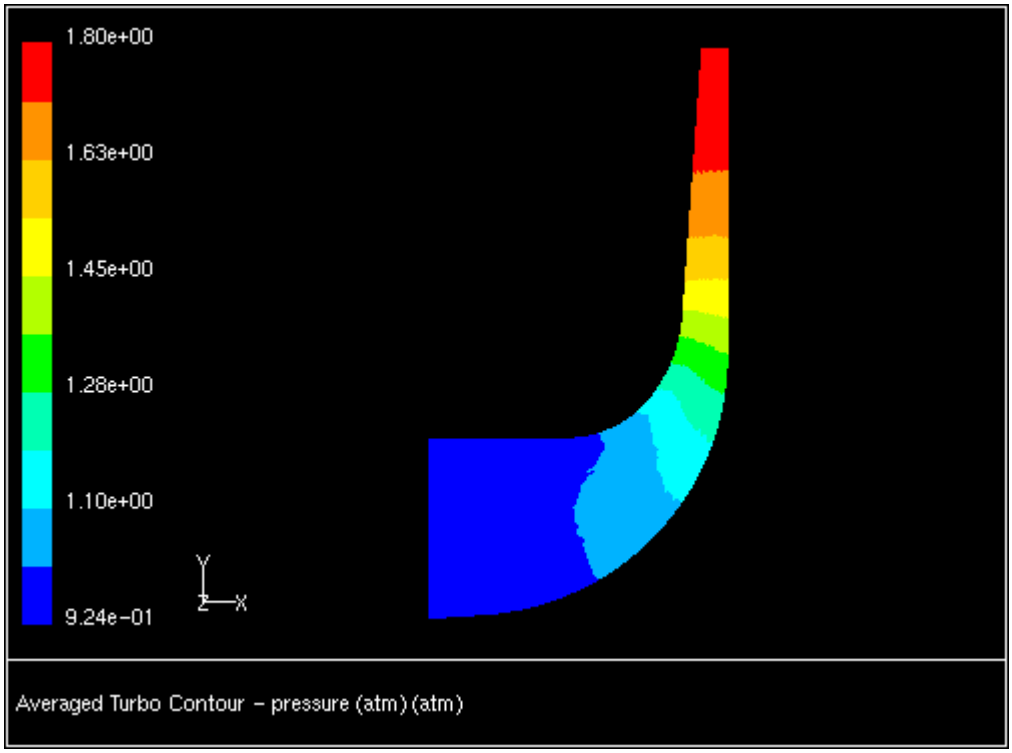
1. Select **All** or a specific predefined turbomachinery topology from the **Turbo Topology** drop-down list.
2. Select the variable or function to be displayed in the **Contours of** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See Turbomachinery-Specific Variables (p. 1872) for a list of turbomachinery-specific variables, and see Field Function Definitions (p. 1931) for an explanation of the variables in the list.)
3. Specify the number of contours in the **Levels** field. The maximum number of levels allowed is 100.
4. Set any of the options described below.
5. Click **Display** to draw the specified contours in the active graphics window.

The resulting display will include the specified number of contours of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

Note that the **Min** and **Max** values displayed in the dialog box are the minimum and maximum averaged values. These limits will in general be different from the global **Domain Min** and **Domain Max**, which are also displayed for your reference (see Figure 31.84: The Turbo Averaged Contours Dialog Box (p. 1868)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 31.85: Turbo Averaged Filled Contours of Static Pressure



31.10.3.2. Contour Plot Options

The options mentioned in the procedure above include drawing color-filled contours (instead of line contours), specifying a range of values to be contoured, and storing the contour plot settings. These options are the same as those in the standard Contours Dialog Box (p. 2676). See Contour and Profile Plot Options (p. 1759) for details about using them.

31.10.4. Displaying Turbomachinery 2D Contours

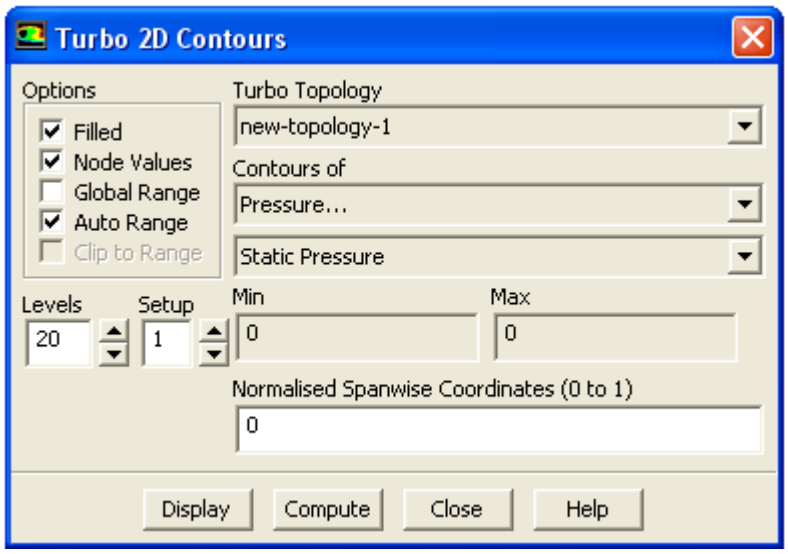
In postprocessing a turbomachinery solution, it is often desirable to display contours on surfaces of constant spanwise coordinate, and then project these contours onto a plane. This permits easier evaluation of the contours, especially for surfaces that are highly three-dimensional.

31.10.4.1. Steps for Generating Turbo 2D Contour Plots

You can display contours using the Turbo 2D Contours Dialog Box (p. 2814) (Figure 31.86: The Turbo 2D Contours Dialog Box (p. 1870)).

Postprocessing → Model Specific → Turbo Topology → 2D Contours...

Figure 31.86: The Turbo 2D Contours Dialog Box



The basic steps for generating a turbo 2D contour plot are as follows:

1. Specify a specific predefined turbomachinery topology using the **Turbo Topology** drop-down list.

2. Enter a value for the **Normalized Spanwise Coordinates (0 to 1)** for the spanwise surface you want to create.

   Important

   If shroud and hub are the curved surfaces, the isosurface very close to them may contain void spaces as ANSYS Fluent displays only a plane cut surface.

3. Select the variable or function to be displayed in the **Contours of** drop-down list.

   First select the desired category in the upper list; you may then select a related quantity in the lower list. See Turbomachinery-Specific Variables (p. 1872) for a list of turbomachinery-specific variables, and see Field Function Definitions (p. 1931) for an explanation of the variables in the list.

4. Specify the number of contours in the **Levels** field. The maximum number of levels allowed is 100.

5. Click **Display** to draw the specified contours in the active graphics window.

The resulting display will include the specified number of contours of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

31.10.4.2. Contour Plot Options

Depending on the type of contour plot you want to display, select appropriate choice under **Options**. These options are the same as those in the standard Contours Dialog Box (p. 2676). See Contour and Profile Plot Options (p. 1759) for details about using them.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.10.5. Generating Averaged XY Plots of Turbomachinery Solution Data

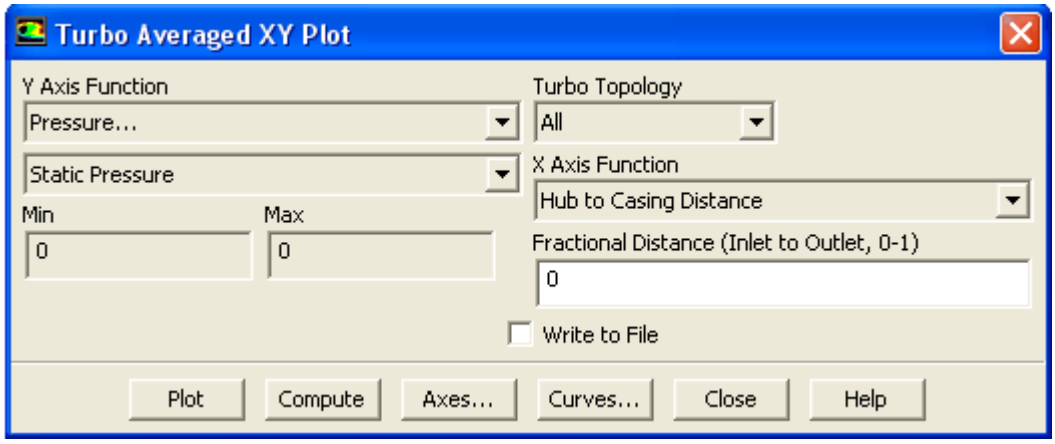
When comparing numerical solutions of turbomachinery problems to experimental data, it is often useful to plot circumferentially averaged quantities in the spanwise and meridional directions. This section describes how to do this in ANSYS Fluent.

31.10.5.1. Steps for Generating Turbo Averaged XY Plots

To create an XY plot of circumferentially averaged solution data, you will use the Turbo Averaged XY Plot Dialog Box (p. 2817) (Figure 31.87: The Turbo Averaged XY Plot Dialog Box (p. 1871)).

Postprocessing → Model Specific → Turbo Topology → Averaged XY Plot...

Figure 31.87: The Turbo Averaged XY Plot Dialog Box



The procedure for generating a turbo averaged XY plot are as follows:

1. Select the variable or function to be plotted in the **Y Axis Function** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See Turbomachinery-Specific Variables (p. 1872) for a list of turbomachinery-specific variables, and see Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

2. Select **All** or a specific predefined turbomachinery topology from the **Turbo Topology** drop-down list.

3. Select the variable or function to be plotted in the **X Axis Function** drop-down list. The choices are **Hub to Casing Distance** and **Meridional Distance**.

4. Specify the desired value in the **Fractional Distance** field. The definition of the fractional distance depends on your selection of **X Axis Function**:

   - If you select **Hub to Casing Distance**, the fractional distance will be **Inlet to Outlet**.
   - If you select **Meridional Distance**, the fractional distance will be **Hub to Casing**.

5. (optional) Modify the attributes of the axes or curves as described in Modifying Axis Attributes (p. 1852) and Modifying Curve Attributes (p. 1854).

6. Click **Plot** to generate the XY plot in the active graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that you can use any of the mouse buttons to annotate the XY plot (see Adding Text to the Graphics Window (p. 1789)).

If you want to write the XY data to a file, follow these steps instead of Step 5 above:

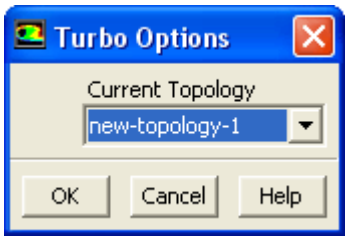
1. Enable the **Write to File** option. The **Plot** button changes to a **Write...** button.
2. Click **Write...**.
3. In The Select File Dialog Box (p. 19), specify a name for the plot file and save it.

31.10.6. Globally Setting the Turbomachinery Topology

In some cases, that is, isosurface creation, ANSYS Fluent enables you to globally set the current turbomachinery topology for your model using the Turbo Options Dialog Box (p. 2819) (Figure 31.88: The Turbo Options Dialog Box (p. 1872)).

Postprocessing → Model Specific → Turbo Topology → Options...

Figure 31.88: The Turbo Options Dialog Box



To set the current topology, select a topology from the **Current Topology** drop-down list and select **OK**.

31.10.7. Turbomachinery-Specific Variables

The following turbomachinery-specific variables are available in ANSYS Fluent:

- **Meridional Coordinate**
- **Abs Meridional Coordinate**
- **Spanwise Coordinate**
- **Abs (H-C) Spanwise Coordinate**
- **Abs (C-H) Spanwise Coordinate**
- **Pitchwise Coordinate**
- **Abs Pitchwise Coordinate**

These variables are contained in the **Mesh...** category of the variable selection drop-down list. See Field Function Definitions (p. 1931) for their definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.11. Fast Fourier Transform (FFT) Postprocessing

When interpreting time-sequence data from a transient solution, it is often useful to look at the data's spectral (frequency) attributes. For instance, you may want to determine the major vortex-shedding frequency from the time-history of the drag force on a body recorded during an ANSYS Fluent simulation. Or, you may want to compute the spectral distribution of static pressure data recorded at a particular location on a body surface. Similarly, you may need to compute the spectral distribution of turbulent kinetic energy using data for fluctuating velocity components. To interpret some of these time dependent data, you need to perform Fourier transform analysis. In essence, the Fourier transform enables you to take any time dependent data and resolve it into an equivalent summation of sine and cosine waves.

ANSYS Fluent enables you to analyze your time dependent data using the Fast Fourier Transform (FFT) algorithm. Information on using the FFT algorithm in ANSYS Fluent is provided in the following sections:

31.11.1. Limitations of the FFT Algorithm
31.11.2. Windowing
31.11.3. Fast Fourier Transform (FFT)
31.11.4. Using the FFT Utility

31.11.1. Limitations of the FFT Algorithm

The following limitations apply to ANSYS Fluent's FFT module:

- The ANSYS Fluent FFT module can only read inputs files in the ANSYS Fluent report file, monitor, and x-y file formats.
- The ANSYS Fluent FFT module assumes that the input data have been sampled at equal intervals and are consecutive (in the order of increasing time).
- The lowest frequency that the FFT module can pick up is given by $1/t$, where t is the total sampling time. If the sampled sequence contains frequencies lower than this, these frequencies will be aliased into higher frequencies.
- The highest frequency that the FFT module can pick up is $1/\left(2dt\right)$, where dt is the sampling interval (or time step).

31.11.2. Windowing

The discrete FFT algorithm is based on the assumption that the time-sequence data passed to the FFT corresponds to a single period of a periodically repeating signal. Since, in most situations, the first and the last data points will not coincide, the repeating signal implied in the assumption can often have a large discontinuity. The large discontinuity produces high-frequency components in the resulting Fourier modes, causing an aliasing error. You can condition the input signal before the transform by "windowing" it, in order to avoid this problem.

Suppose that we have N consecutive discrete (time-sequence) data sampled with a constant interval, Δt:

$$\phi_k \equiv \phi\left(t_k\right), \quad t_k \equiv k\Delta t, \qquad k=0,1,2,\ldots,\left(N-1\right) \tag{31.28}$$

Windowing is done by multiplying the original input data (ϕ_j) by a window function, W_j:

$$\tilde{\phi}_j = \phi_j W_j \qquad j=0,1,2,\ldots,\left(N-1\right) \tag{31.29}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ANSYS Fluent offers four different window functions:

Hamming's window:

$$W_j = \begin{cases} 0.54 - 0.46\cos\left(\frac{8\pi j}{N}\right) & j \le \frac{N}{8},\ j \ge \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \tag{31.30}$$

Hanning's window:

$$W_j = \begin{cases} 0.5\left[1 - \cos\left(\frac{8\pi j}{N}\right)\right] & j \le \frac{N}{8},\ j \ge \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \tag{31.31}$$

Barlett's window:

$$W_j = \begin{cases} \frac{8j}{N} & j \le \frac{N}{8} \\ 8\left(1 - \frac{j}{N}\right) & j \ge \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \tag{31.32}$$

Blackman's window:

$$W_j = \begin{cases} 0.42 - 0.5\cos\left(\frac{8\pi j}{N}\right) + 0.08\cos\left(\frac{16\pi j}{N}\right) & j \le \frac{N}{8},\ j \ge \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \tag{31.33}$$

These window functions preserve a large fraction $(3/4)$ of the original data, affecting only $1/4$ of the data on both ends.

31.11.3. Fast Fourier Transform (FFT)

The Fourier transform utility in ANSYS Fluent enables you to compute the Fourier transform of a signal, $\phi(t)$, a real-valued function, from a finite number of its sampled points.

For a periodic set of N sampled points, ϕ_k, the discrete Fourier transform [13] (p. 2887) expresses the signal as a finite trigonometric series:

$$\phi_k = \sum_{n=0}^{N-1} \hat{\phi}_n e^{2\pi i k n / N} \qquad k = 0, 1, 2, \ldots (N-1) \tag{31.34}$$

where the series coefficients $\hat{\phi}_n$ are computed as

$$\hat{\phi}_n = \frac{1}{N} \sum_{k=0}^{N-1} \phi_k e^{-2\pi i k n / N} \qquad n = 0, 1, 2, \ldots (N-1) \tag{31.35}$$

Equation 31.34 (p. 1874) and Equation 31.35 (p. 1874) form a Fourier transform pair that enables us to determine one from the other.

Note that when we follow the convention of varying n from 0 to $N-1$ in Equation 31.34 (p. 1874) and Equation 31.35 (p. 1874) instead of from $-N/2$ to $N/2$, the range of index $1 \le n \le N/2 - 1$ corresponds to positive frequencies, and the range of index $N/2 + 1 \le n \le N-1$ corresponds to negative frequencies. $n = 0$ still corresponds to zero frequency.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the actual calculation of the transforms, ANSYS Fluent adopts the so-called fast Fourier transform (FFT) algorithm, which significantly reduces operation counts in comparison to the direct transform. Furthermore, unlike most FFT algorithms in which the number of data should be a power of 2, the FFT utility in ANSYS Fluent employs a prime-factor algorithm [121] (p. 2893). The number of data points permissible in the prime-factor FFT algorithm is any products of mutually prime factors from the set $2,3,4,5,7,8,9,11,13,16$, with a maximum value of $720720=5\times7\times9\times11\times13\times16$. Thus, the prime-factor FFT preserves the original data better than the conventional FFT.

Just prior to computing the transform, ANSYS Fluent determines the largest permissible number of data points based on the prime factors, discarding the rest of the data. A list of these numbers is provided in Table 31.2: Numbers of Data Points Supported by the Prime-Factor FFT Algorithm (p. 1875).

Table 31.2: Numbers of Data Points Supported by the Prime-Factor FFT Algorithm

2	70	220	572	1386	3120	8580	34320

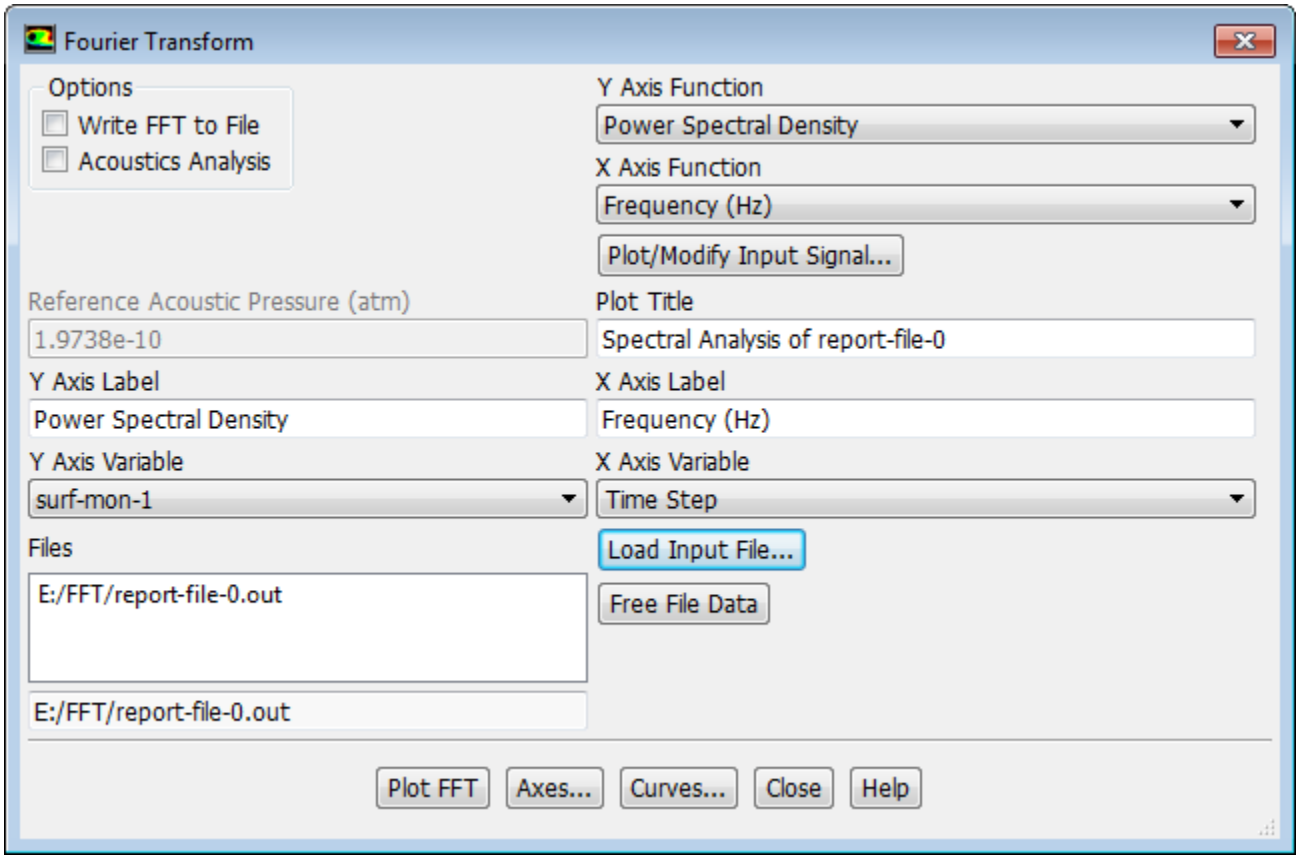
31.11.4. Using the FFT Utility

The ANSYS Fluent FFT utility is available through the Fourier Transform Dialog Box (p. 2602) (Figure 31.89: The Fourier Transform Dialog Box (p. 1876)).

Results → Plots → FFT → Set Up...

Figure 31.89: The Fourier Transform Dialog Box



31.11.4.1. Loading Data for Spectral Analysis

FFT analysis requires an input signal data file consisting of time-sequence data. To load an input signal data file into the Fourier Transform Dialog Box (p. 2602), click **Load Input File...**. This displays The Select File Dialog Box (p. 19) where you can browse through your file directories and locate your data file containing your time-sequence data. To remove a file from the **Files** list, select it and then click **Free File Data**.

If you computed acoustic signals "on the fly", you have the option of processing signal data from a file or processing receiver data stored in memory. To analyze signal data from an existing input file, select **Process File Data** under **Process Options** and proceed as described above. To analyze receiver data stored in memory, select **Process Receiver** under **Process Options** and select the appropriate receiver in the **Receiver** list.

Click **Plot FFT** to display the spectral analysis data and, if you have enabled **Acoustics Analysis**, to calculate the overall sound pressure level in dB based on the **Reference Acoustic Pressure** and display it in the console.

Note

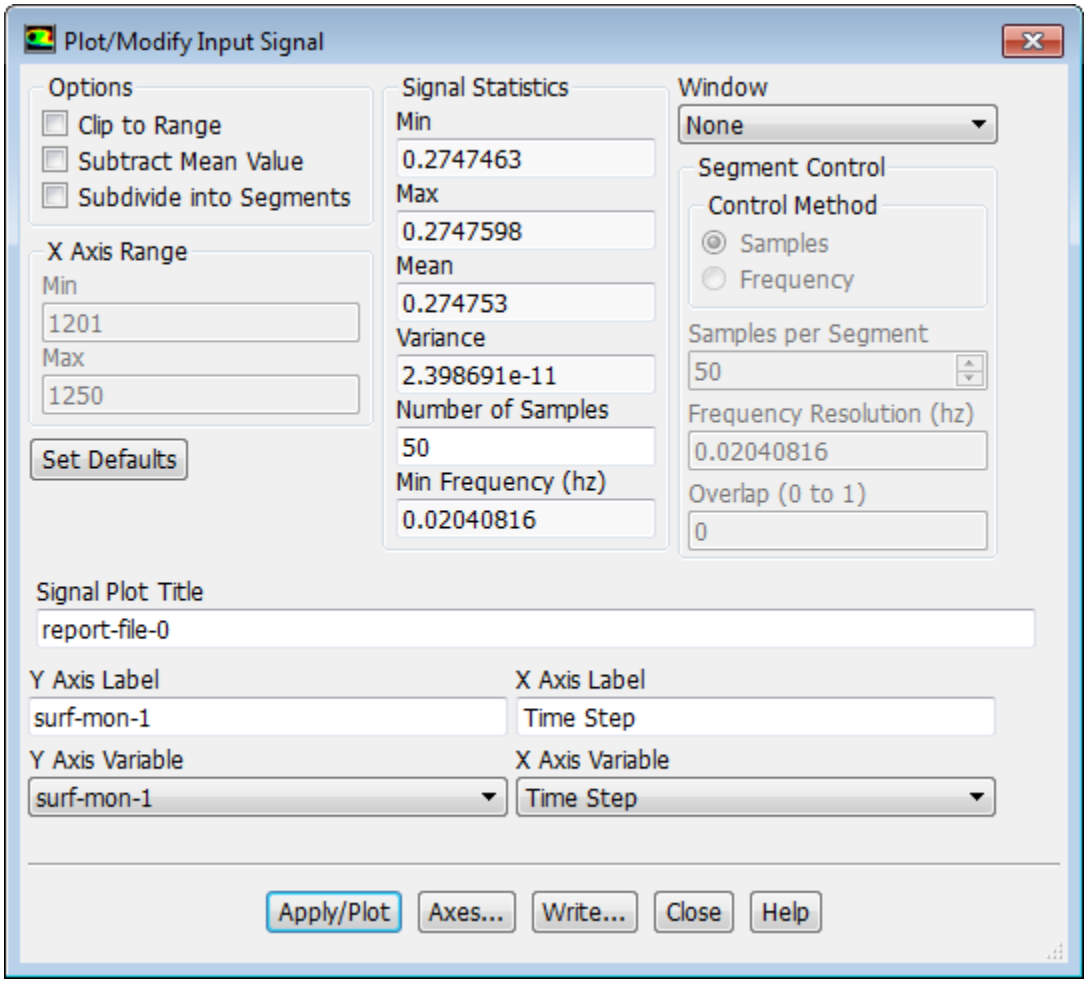
You can specify the y axis and x axis variables if your input report file contains multiple report definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.11.4.2. Customizing the Input and Defining the Spectrum Smoothing

With the input signal data file loaded into the Fourier Transform Dialog Box (p. 2602), you may want to view a plot of the input signal and/or customize the data set in preparation for applying the FFT algorithm. To do so, click the **Plot/Modify Input Signal** button to open the Plot/Modify Input Signal Dialog Box (p. 2605) (Figure 31.90: The Plot/Modify Input Signal Dialog Box (p. 1877)).

Figure 31.90: The Plot/Modify Input Signal Dialog Box



The Plot/Modify Input Signal Dialog Box (p. 2605) allows you to analyze a portion of the input signal, view input **Signal Statistics**—**Min**, **Max**, **Mean**, **Variance**, total **Number of Samples**, and **Min Frequency** (that is, the finest possible frequency resolution)—and set title and label information for the input signal plot. Additionally, this dialog box allows you to enable and control the smoothing of the resulting spectrum by subdividing the input signal into multiple segments and averaging the segment-based spectra.

Note

You can specify the y axis and x axis variables if your input report file contains multiple report definitions.

31.11.4.2.1. Customizing the Input Signal Data Set

By default, the entire data set is analyzed. To analyze a portion of the input signal, enable the **Clip to Range** option and specify the data range by entering **Min** and **Max** values under **X Axis Range**. To have the y-axis quantities reduced by the **Mean** value of the relevant signal property, enable the **Subtract Mean Value** option.

The **Set Defaults** button will reset the original values for the **Min** and **Max** fields under **X Axis Range** and turn off the **Clip to Range** option.

31.11.4.2.2. Spectrum Smoothing Through Signal Segmentation

For long broadband noise signals, the computed Fourier spectrum may display spurious fluctuations of amplitudes between the neighboring modes. In order to obtain a smooth spectrum, you can split the signal into multiple overlapping segments so that ANSYS Fluent can apply the FFT algorithm on each segment and then average the resulting spectra. This procedure allows you to significantly suppress the spurious fluctuations at the cost of coarsening the frequency resolution of the spectrum. Note that the arithmetic averaging of spectra is performed for the squares of Fourier amplitudes, thus conserving the signal energy.

To use the smoothing procedure, enable the **Subdivide into Segments** option and define the segment size and the overlap of the subsequent segments in the **Segment Control** group box. Make a selection from the **Control Method** list to specify how you want to define the segment size: select **Samples** if you want to specify the number of **Samples per Segment**; select **Frequency** if you want to specify the desired **Frequency Resolution** Δf in Hertz units (the segment length in seconds is then equal to $1/\Delta f$). To help determine a suitable segment size, you can use the **Number of Samples** and the **Min Frequency** information in the **Signal Statistics** group box. Note that the final segment length is selected by ANSYS Fluent to adhere to the largest supported number of data samples (see Table 31.2: Numbers of Data Points Supported by the Prime-Factor FFT Algorithm (p. 1875)). The actual signal length and the number of segments will be displayed in the console when you plot or write the Fourier spectrum. The number of segments depends on the **Overlap** of the subsequent segments, which is specified regardless of which **Control Method** you select. If you select a **Window** function (see Windowing (p. 1873) for details), it is recommended that you use an **Overlap** value of at least 0.125, in order to cover the signal portion affected by the window function. Generally, an **Overlap** value of 0.5 is recommended. The exact number of samples that are in the overlapping region of the segment can be determined from the segment hop size, which is displayed in the console. The segment hop size is the distance (in terms of samples) between the starting samples of any two adjacent segments (that is, the shift from one segment to the next), and has a minimum value of 1.

The **Set Defaults** button will reset the segment control values and disable the **Subdivide into Segments** option.

31.11.4.2.3. Viewing Data Statistics

To aid in the signal analysis, whether for the entire input signal or for a certain range of data, the **Signal Statistics** group box in the Plot/Modify Input Signal Dialog Box (p. 2605) displays signal information such as the minimum, maximum, and average signal values, as well as the signal variance, total number of samples, and finest possible frequency resolution.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.11.4.2.4. Customizing Titles and Labels

You can create a new title or edit the original title for the input signal plot by entering a text string in **Signal Plot Title**. Likewise, you can create a new axis label or edit the original axis label by entering a text string into either **Y Axis Label** or **X Axis Label**.

31.11.4.2.5. Applying the Changes in the Input Signal Data

To apply any changes you have made in the Plot/Modify Input Signal Dialog Box (p. 2605) and view a plot of the input signal, click **Apply/Plot**.

31.11.4.3. Customizing the Output

In most practical applications with CFD data, you may want to find out how much power or energy is contained in a certain frequency range, but do not want to distinguish positive and negative frequency. In recognition of this, all the outputs from the FFT module in ANSYS Fluent pertain to *one-sided spectra* for the range of positive frequency.

The Fourier Transform Dialog Box (p. 2602) (Figure 31.89: The Fourier Transform Dialog Box (p. 1876)) and Plot/Modify Input Signal Dialog Box (p. 2605) (Figure 31.90: The Plot/Modify Input Signal Dialog Box (p. 1877)) enable you to set several different functions for the x and y axes, apply different FFT windowing techniques, and set various output options.

31.11.4.3.1. Specifying a Function for the Axis

You can choose the y-axis function using the **Y Axis Function** drop-down list. Available options for the y-axis functions are as follows. Note that the functions related to acoustics (all of which are measured in dB) are only available when the **Acoustics Analysis** option is enabled.

The definitions are provided for $n \le N/2$, and include contributions from both elements of a complex conjugate pair n and N-n. Note that in ANSYS Fluent, the value of N is always an even number.

Power Spectral Density
is the distribution of signal power in the frequency domain. Its value and units depend on the **X Axis Function** choice. For the detailed spectral representation with all resolved harmonics (that is, when **X Axis Function** is either **Frequency**, **Strouhal Number**, or **Fourier Mode**), the **Power Spectral Density** (PSD) has units of the signal magnitude squared over the frequency (for example, Pa^2/Hz) and is defined for the frequency f_n as

$$PSD(f_n) = E(f_n)/\Delta f \qquad n = 1,2,...,N/2 \tag{31.36}$$

where Δf is the frequency step in the discrete spectrum, and the Fourier mode power $E(f_n)$ is computed as

$$E(f_n) = \begin{cases} 0.5\left(2|\hat{\phi}_n|\right)^2 & n = 1,2,...,N/2-1 \\ |\hat{\phi}_n|^2 & n = N/2 \end{cases} \tag{31.37}$$

For the octave analysis (that is, when the **X Axis Function** is either **Octave Band** or **1/3-Octave Band**), the **Power Spectral Density** has units of the signal magnitude squared (for example, Pa^2), and is defined for the frequency band f_{band} as

$$PSD(f_{\text{band}}) = \sum E(f_n) \tag{31.38}$$

where n includes all of the Fourier modes belonging to the band.

Magnitude
is the amplitude. For the detailed spectral representation with all resolved harmonics (that is, when **X Axis Function** is either **Frequency**, **Strouhal Number**, or **Fourier Mode**), the **Magnitude** (A) is defined for the frequency f_n as

$$(f_n) = \begin{cases} |\hat{\phi}_n| & n=0, N/2 \\ 2|\hat{\phi}_n| & n=1,2,...,N/2-1 \end{cases} \tag{31.39}$$

where $A\left(f_0\right)$ is the mean signal value.

For the octave analysis (that is, when the **X Axis Function** is either **Octave Band** or **1/3-Octave Band**), the **Magnitude** is defined for the frequency band f_{band} as

$$A\left(f_{\text{band}}\right) = \sqrt{2PSD\left(f_{\text{band}}\right)} \tag{31.40}$$

where $PSD\left(f_{\text{band}}\right)$ is calculated according to Equation 31.38 (p. 1880).

Sound Pressure Level (dB)
is the decibel level. For either general or acoustic data, when the sampled data is pressure (for example, static pressure or sound pressure), the **Sound Pressure Level (dB)** (L_{sp}) is calculated in decibel units using

$$L_{\text{sp}} = 10\left(\log\frac{PSD}{p_{\text{ref}}^2}\right) \quad (\text{dB}) \tag{31.41}$$

where PSD is the **Power Spectral Density** for either a particular Fourier mode or a particular frequency band (see Equation 31.36 (p. 1879) and Equation 31.38 (p. 1880)). p_{ref} is the reference acoustic pressure, with a default value of 2 × 10^{-5} Pa; you can revise this value, as described in Enabling the FW-H Acoustics Model (p. 1208).

Sound Amplitude (dB)
is similar to the **Sound Pressure Level (dB)**, and is a logarithmic conversion of the pressure signal **Magnitude** into decibel units. The **Sound Amplitude (dB)** (A_{sp}) is calculated for either a Fourier mode or a frequency band using

$$A_{\text{sp}} = 10\left(\log\frac{A}{p_{\text{ref}}}\right) \quad (\text{dB}) \tag{31.42}$$

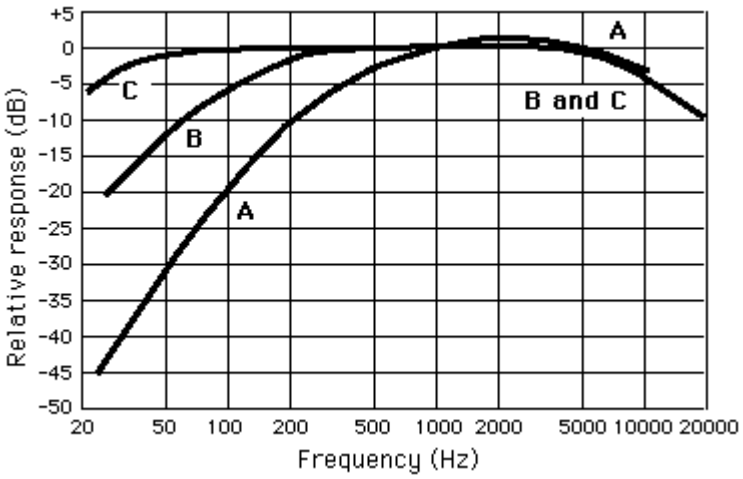
A-Weighted, Sound Pressure Level (dB A)
is the calculated sound pressure level weighted by the A-scale function to more closely approximate the frequency response of the human ear. A-Weighting is applied for loudness levels below 55 phons (55 dB at 1 kHz) and is the most commonly used weighting function. See Figure 31.91: A-, B-, and C-Weighting Functions (p. 1881) for a graphical representation. This function is only available when the **X Axis Function** is either **Octave Band** or **1/3-Octave Band**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

B-Weighted, Sound Pressure Level (dB B)
is the calculated sound pressure level weighted by the B-scale function. B-Weighting is applied to loudness levels between 55 and 85 phons, though it is rarely used. See Figure 31.91: A-, B-, and C-Weighting Functions (p. 1881) for a graphical representation. This function is only available when the **X Axis Function** is either **Octave Band** or **1/3-Octave Band**.

C-Weighted, Sound Pressure Level (dB C)
is the calculated sound pressure level weighted by the C-scale function. C-Weighting is applied for loudness levels above 85 phons and is commonly used for high-intensity sound such as traffic studies. See Figure 31.91: A-, B-, and C-Weighting Functions (p. 1881) for a graphical representation. This function is only available when the **X Axis Function** is either **Octave Band** or **1/3-Octave Band**.

Figure 31.91: A-, B-, and C-Weighting Functions



Further graphical customizations for the y-axis are available by clicking the **Axes...** button. For more information, see Modifying Axis Attributes (p. 1852).

31.11.4.3.2. Specifying a Function for the X Axis

There are three options for the x-axis function you can choose from in order to plot or write the detailed spectrum with all resolved Fourier modes; these three options are related to the discrete frequencies at which the Fourier coefficients are computed. There are also two additional options available when the **Acoustics Analysis** option is enabled, which allow the octave and 1/3 octave band analysis. You can apply specific analytic functions for the x-axis using the **X Axis Function** drop-down list.

Available options for the x-axis functions are as follows. The definitions are provided for $n \le N/2$, because the corresponding definitions for the y-axis functions include contributions from both elements of a complex conjugate pair n and N-n. Note that in ANSYS Fluent, the value of N is always an even number.

Frequency (Hz)
is defined as:

$$f_n = \frac{1}{N\Delta t} n \qquad n = 0, 1, 2, \ldots, N/2 \tag{31.43}$$

where N is the number of data points used in the FFT.

Strouhal Number
is the nondimensionalized version of the frequency defined in Equation 31.43 (p. 1881) :

$$St_n \equiv \frac{f_n L_{ref}}{U_{ref}} \tag{31.44}$$

where L_{ref} and U_{ref} are the reference length and velocity scales specified in the Reference Values Task Page (p. 2502).

Fourier Mode

is the index in Equation 31.34 (p. 1874) and/or Equation 31.35 (p. 1874), which represents the n^{th} term in the Fourier transform of the signal.

Octave Band (Hz)

is a range of discrete frequency bands for different octaves within the threshold of hearing. The range of each octave band is double to that of the previous band (see Table 31.3: Octave Band Frequencies and Weightings (p. 1882)).

1/3-Octave Band (Hz)

is a range of discrete frequency bands for different 1/3 octaves within the threshold of hearing.

Table 31.3: Octave Band Frequencies and Weightings

Lower Freq. (Hz)	Center Freq. (Hz)	Upper Freq. (Hz)	dB A	dB B	dB C
11	16	22	-56.7	-28.5	-8.5
22	31.5	45	-39.4	-17.1	-3.0
45	63	90	-26.2	-9.3	-0.8
90	125	180	-16.1	-4.2	-0.2
180	250	355	-8.6	-1.3	0.0
355	500	710	-3.2	-0.3	0.0
710	1000	1400	0.0	0.0	0.0
1400	2000	2800	1.2	-0.1	-0.2
2800	4000	5600	1.0	-0.7	-0.8
5600	8000	11200	-1.1	-2.9	-3.0
11200	16000	22400	-6.6	-8.4	-8.5

Further graphical customizations for the x-axis are available by clicking **Axes...**. For more information, see Modifying Axis Attributes (p. 1852).

31.11.4.3.3. Specifying Output Options

You can write out the FFT data directly to a file by choosing the **Write FFT to File** option under **Options** in the Fourier Transform Dialog Box (p. 2602). Once the **Write FFT to File** option is selected, click **Write FFT** to display a file selection dialog box where you can choose a file and/or a location to hold the FFT data. If **Acoustics Analysis** is selected, the overall sound pressure level will be calculated in dB (based on the **Reference Acoustic Pressure**) and displayed in the console at this time.

Further customizations for how the FFT data is displayed are available by clicking **Curves...**. For more information, see Modifying Curve Attributes (p. 1854).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

31.11.4.3.4. Specifying a Windowing Technique

You can use the various windowing techniques described in Windowing (p. 1873) by selecting any of the **Window** options in the Plot/Modify Input Signal Dialog Box (p. 2605). By default, **None** is selected so that no windowing technique is applied.

31.11.4.3.5. Specifying Labels and Titles

You can assign a title for your FFT plot using the **Plot Title** text field. You can also assign y-axis and x-axis labels for your FFT plot using the **Y Axis Label** and **X Axis Label** text fields, respectively. By default,ANSYS Fluent assigns the **Y Axis Label** and the **X Axis Label** to the particular selection of **Y Axis Function** and **X Axis Function**.

Chapter 32: Reporting Alphanumeric Data

ANSYS Fluent provides tools for computing and reporting integral quantities at surfaces and boundaries. These tools enable you to find the mass flow rate and heat transfer rate through boundaries, the forces and moments on boundaries, and the area, integral, flow rate, average, and mass average (among other quantities) on a surface or in a volume. In addition, you can print histograms of geometric and solution data, set reference values for the calculation of non-dimensional coefficients, and compute projected surface areas. You can also print or save a summary report of the models, boundary conditions, and solver settings in the current case. These features are described in the following sections.

32.1. Reporting Conventions
32.2. Monitoring and Reporting Solution Data
32.3. Creating Output Parameters
32.4. Fluxes Through Boundaries
32.5. Forces on Boundaries
32.6. Projected Surface Area Calculations
32.7. Surface Integration
32.8. Volume Integration
32.9. Histogram Reports
32.10. Discrete Phase
32.11. S2S Information
32.12. Reference Values
32.13. Summary Reports of Case Settings
32.14. System Resource Usage

Reporting tools for the discrete phase are described in Postprocessing for the Discrete Phase (p. 1329).

32.1. Reporting Conventions

For 2D problems, ANSYS Fluent computes all integral quantities for a unit depth equivalent to 1 meter. This value can be adjusted to match the specific dimension of your application only by manually revising the **Depth** in the Reference Values Task Page (p. 2502) (see Reference Values (p. 1924)).

Important

The default value of **Depth** will be equivalent to 1 meter, even if the units are changed for **depth** in the Set Units Dialog Box (p. 2166) (for example, if the units for **depth** are changed to cm in the Set Units Dialog Box (p. 2166), the value of **Depth** in the Reference Values Task Page (p. 2502) will be 100 cm).

For axisymmetric problems, all integral quantities are computed for an angle of 2π radians.

32.2. Monitoring and Reporting Solution Data

During the course of a simulation, you may want to monitor, print, write, and/or plot solution data; this is done using report definitions. A report definition is an object that specifies a certain quantity or set

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of values to be computed at the end of a solver timestep or iteration. You can then choose to have multiple report definitions printed to the console, written to a single file, or plotted in the same window.

You can use report definitions to monitor convergence, verify mesh independence, and record time-histories. These report definitions can monitor the value of field variables or functions through specified operations, such as surface, volume, force, moment, and flux integrals.

Once you create report definitions, they can be added to a report file. Report files can include multiple report definitions of varied types. Multiple report definitions can be plotted in the same graphics window by adding them to a single report plot. One report definition can be included in multiple report plots and files. For additional information on report files and plots, see Report Files and Report Plots (p. 1903).

32.2.1. Creating Report Definitions

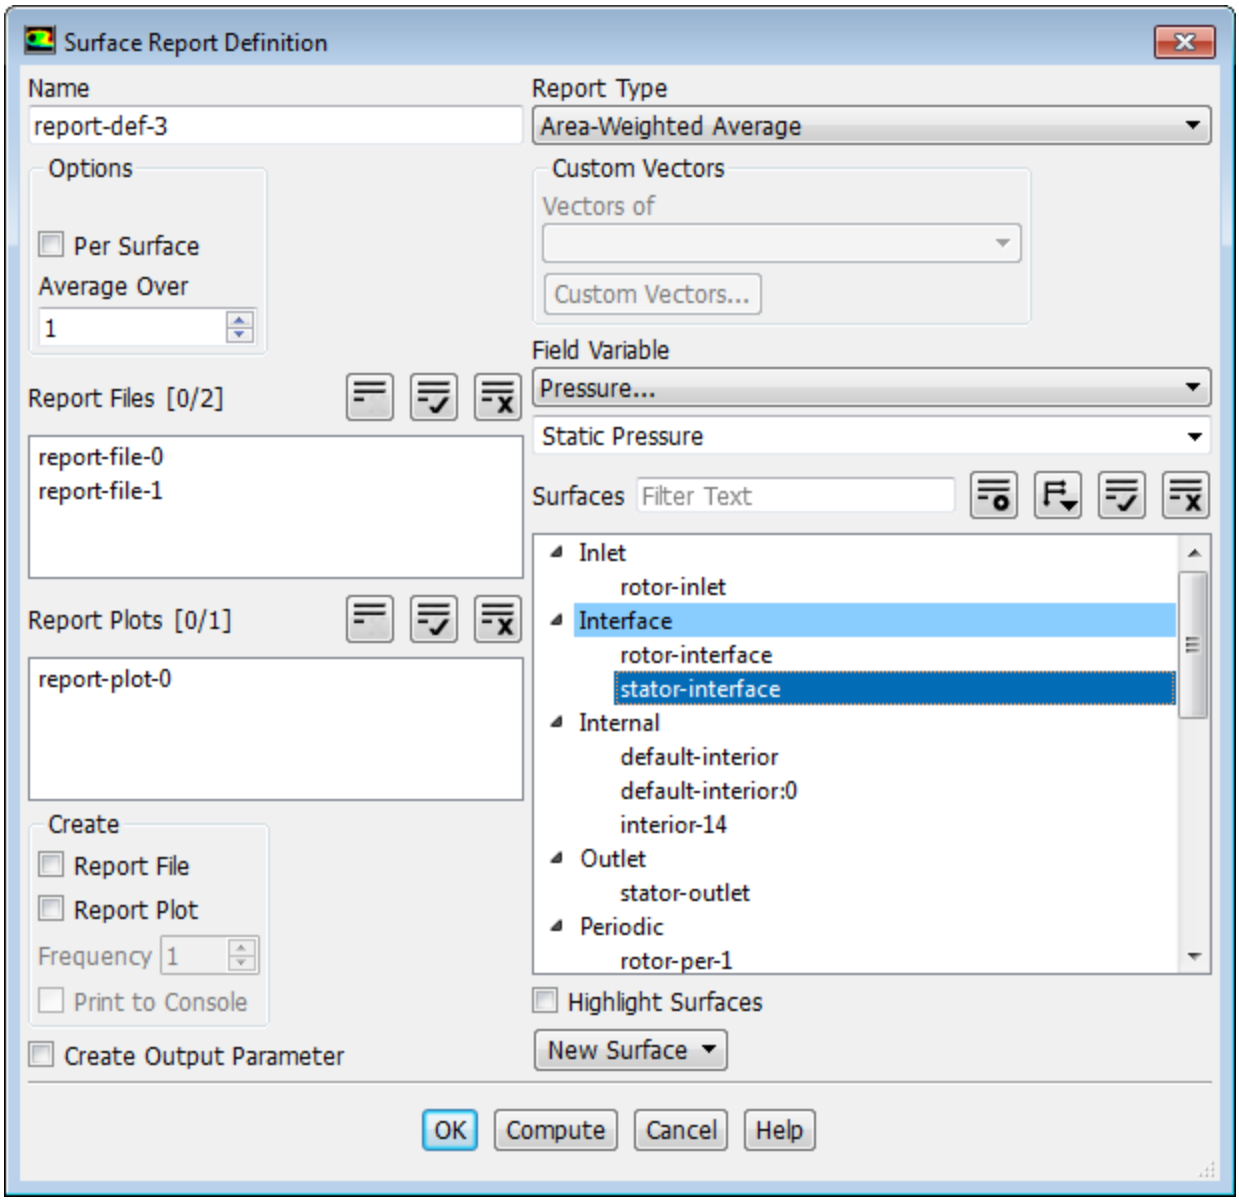
You can create report definitions from multiple locations in Fluent, allowing you to quickly define report definitions, regardless of where you are in your workflow. The primary method to create a report definition is through the ribbon. For example:

Solving → **Reports** → **Definitions** → **New** → **Surface Report** → **Area-Weighted Average...**

Opens the **Surface Report Definition** dialog box.

Alternative methods for accessing this dialog box are through the tree, by right-clicking the ***Report Definition*** *branch, or through the* ***New*** *drop-down list in the* *Figure 32.1: Report Definitions Dialog Box (p. 1889)*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Many of the setup steps are the same or similar when setting up the various types of report definitions.

To setup the Surface Report Definition dialog box:

1. Enter a name for the report definition under **Name**.
2. If you want the value reported on individual surfaces rather than the net results from a group of surfaces, enable the **Per Surface** option.
3. (optional) To have Fluent calculate a running average for the **Surface Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

   Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

   The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If you want the report definition written to a file or plotted, either select an existing report file or plot from the **Report Files** or **Report Plots** lists, or create a new report file or plot by enabling **Report File** and/or **Report Plot** in the **Create** group box.

5. If you want the report definition available as an output parameter, enable **Create Output Parameter**.

6. Choose the surface report definition integration method by selecting **Area**, **Integral**, **Standard Deviation**, **Flow Rate**, **Mass Flow Rate**, **Volume Flow Rate**, **Area-Weighted Average**, **Mass-Weighted Average**, **Sum**, **Uniformity Index - Mass Weighted**, **Uniformity Index - Area Weighted**, **Facet Average**, **Facet Minimum**, **Facet Maximum**, **Vertex Average**, **Vertex Minimum**, **Vertex Maximum**, **Custom Vector Based Flux**, **Custom Vector Flux**, or **Custom Vector Weighted Average** from the **Report Type** drop-down list. These methods are described in Surface Integration (p. 1920).

7. If you selected **Custom Vector Based Flux**, **Custom Vector Flux**, or **Custom Vector Weighted Average** from the **Report Type** drop-down list, you must define the vectors in the **Custom Vectors** group box.

8. Unless you are reporting a mass flow rate or volume flow rate, specify the variable or function to be integrated in the **Field Variable** drop-down list. First select the desired category in the upper drop-down list. You can then select one of the related quantities in the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.) If you are running a multiphase simulation you may need to select the phase of interest (or **mixture**) from the **Phase** drop-down list (depending on the field variable selected).

   Note

   - In general, you can select any arbitrary field variable for each report type. However, not all possible combinations are physically meaningful.
   - For multiphase flow, you should use only the **Mass Flow Rate** integral to compute the mass flow rate of the mixture or for an individual phase. Do not use the **Flow Rate** integral of the **Volume Fraction** field variable as this will result in erroneous results.

9. Select the **Surfaces** where you want Fluent to evaluate the specified variable.

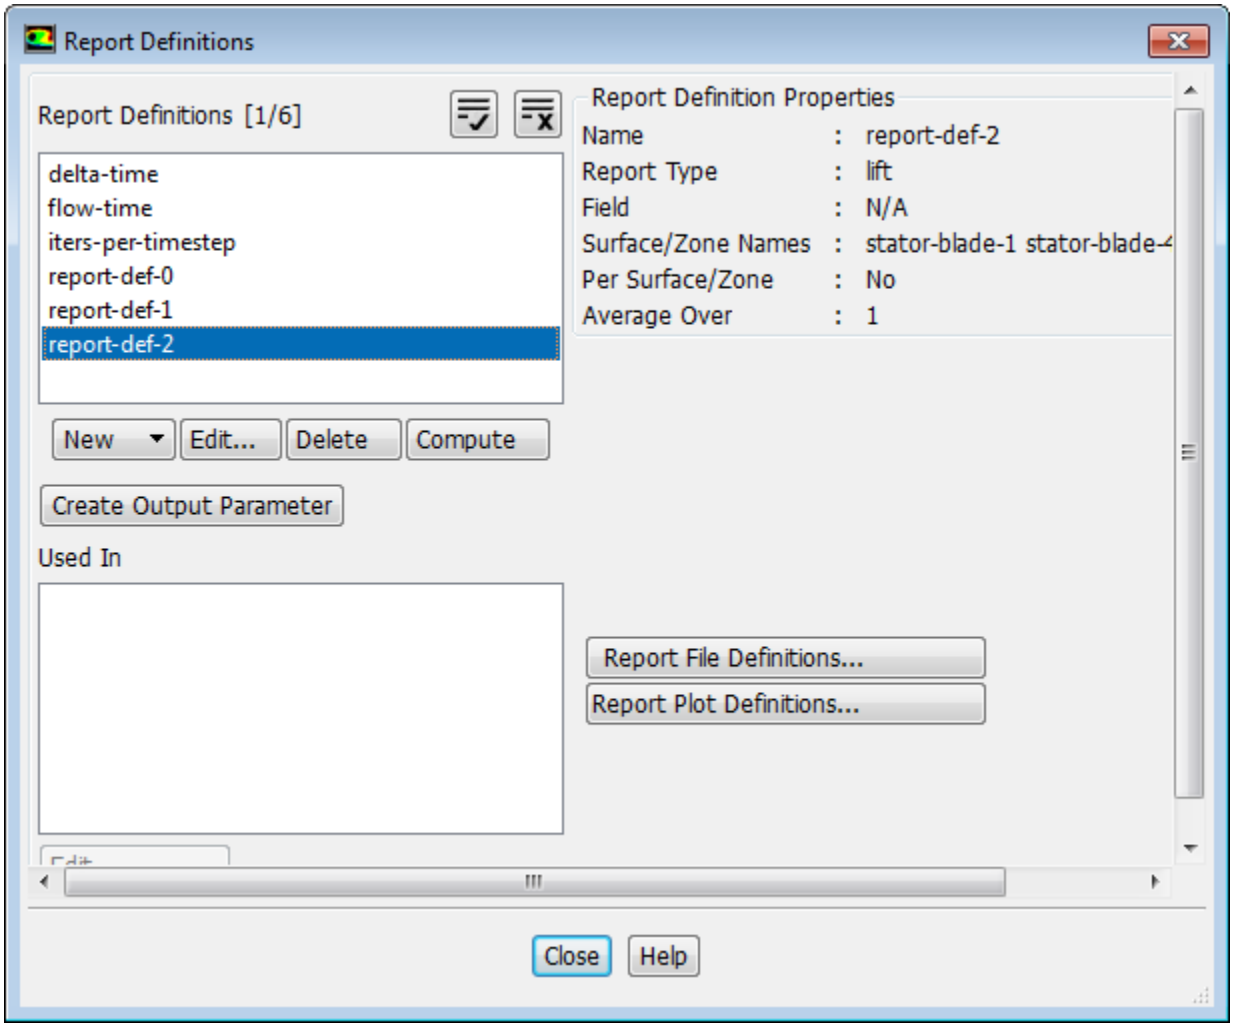
10. You have the option to highlight a selected surface and have it displayed in the graphics window by enabling **Highlight Surfaces**.

11. Click **OK** to create the report definition and close the dialog box.

Once you have created a report definition, it appears in the Figure 32.1: Report Definitions Dialog Box (p. 1889).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.1: Report Definitions Dialog Box



You can use this dialog box to review and modify the properties of the existing report definitions.

The following sections detail setup instructions that are specific to each type of report definition.

32.2.1.1. Surface Report definitions
32.2.1.2. Volume Report definitions
32.2.1.3. Force and Moment Report definitions
32.2.1.4. Flux Report Definition
32.2.1.5. DPM Report Definition
32.2.1.6. User Defined Report Definition
32.2.1.7. Expression Report Definition

32.2.1.1. Surface Report definitions

You can use the Figure 32.2: Surface Report Definition Dialog Box (p. 1891) to create surface report definitions. There are many different types of surface-based report definitions that you can create, including:

- Integral
- Standard Deviation

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

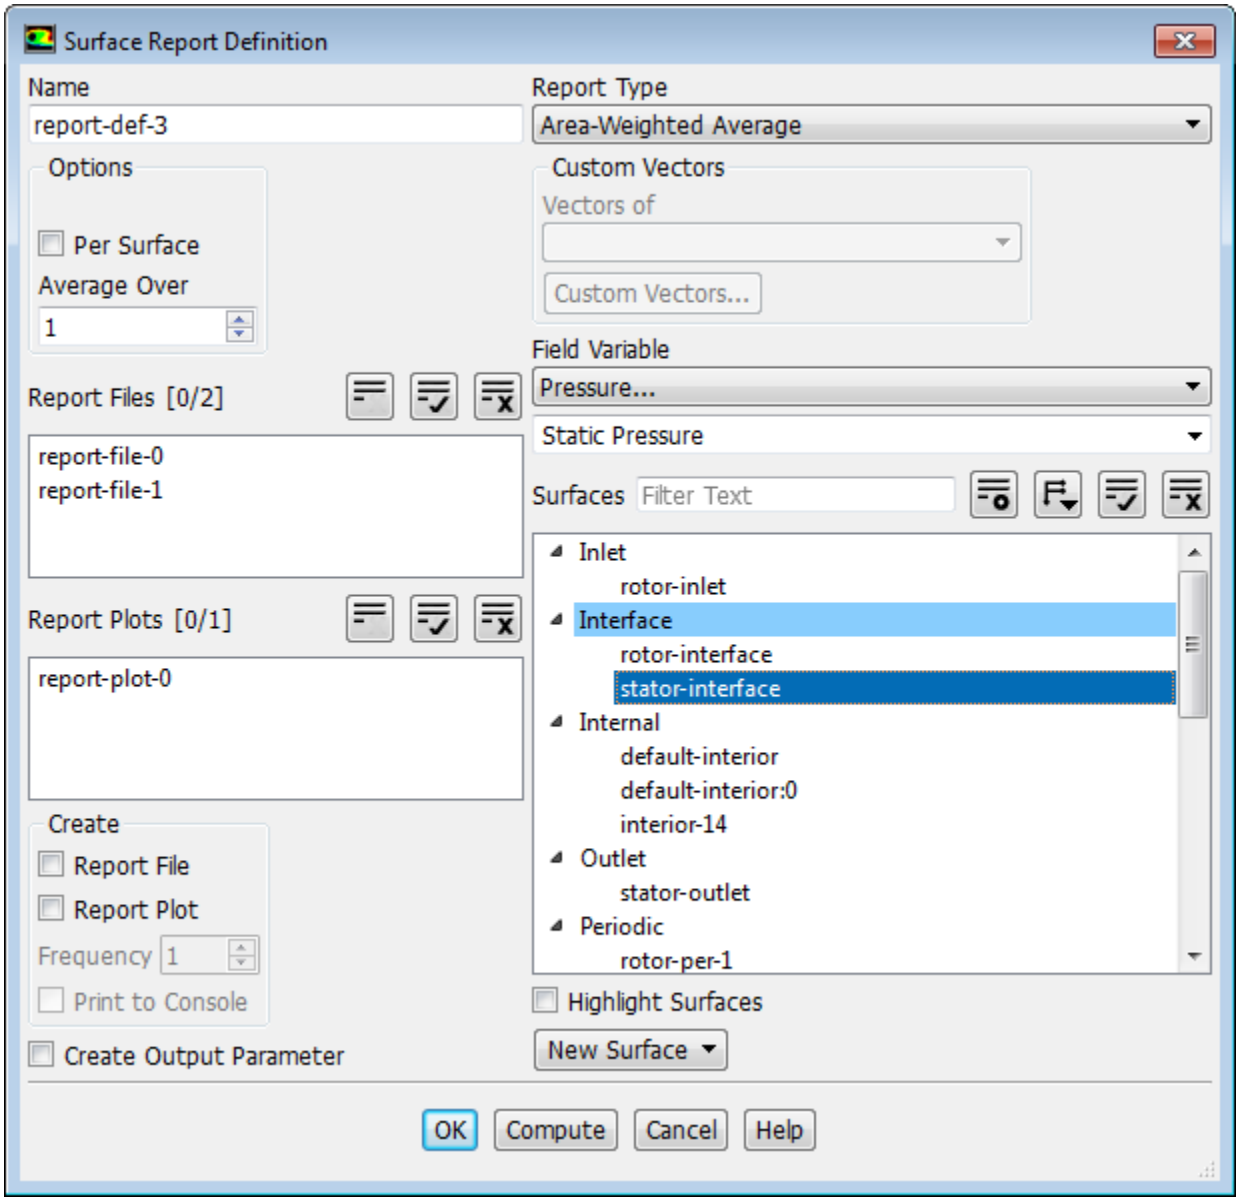
- Flow Rate
- Mass Flow Rate (non-field based)
- Volume Flow Rate (non-field based)
- Area-Weighted Average
- Mass-Weighted Average
- Sum
- Uniformity Index — Mass Weighted
- Uniformity Index — Area Weighted
- Facet Average
- Facet Minimum
- Facet Maximum
- Custom Vector Based Flux (custom-vector based)
- Custom Vector Flux (custom-vector based, non-field based)
- Custom Vector Weighted Average (custom-vector based)

To plot or write the surface report definition data you must use a **Report File** or **Report Plot**. If a surface report definition is already included in a report file/plot, then that report file/plot will be highlighted. If you de-select a report file/plot that had included the current report definition and click **OK**, the report definition will be removed from that report file/plot. For additional information on report files and plots, see Report Files and Report Plots (p. 1903).

Solving → **Reports** → **Definitions** → **New** → **Surface Report**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.2: Surface Report Definition Dialog Box



The procedure for creating surface report definitions is covered in Creating Report Definitions (p. 1886).

32.2.1.2. Volume Report definitions

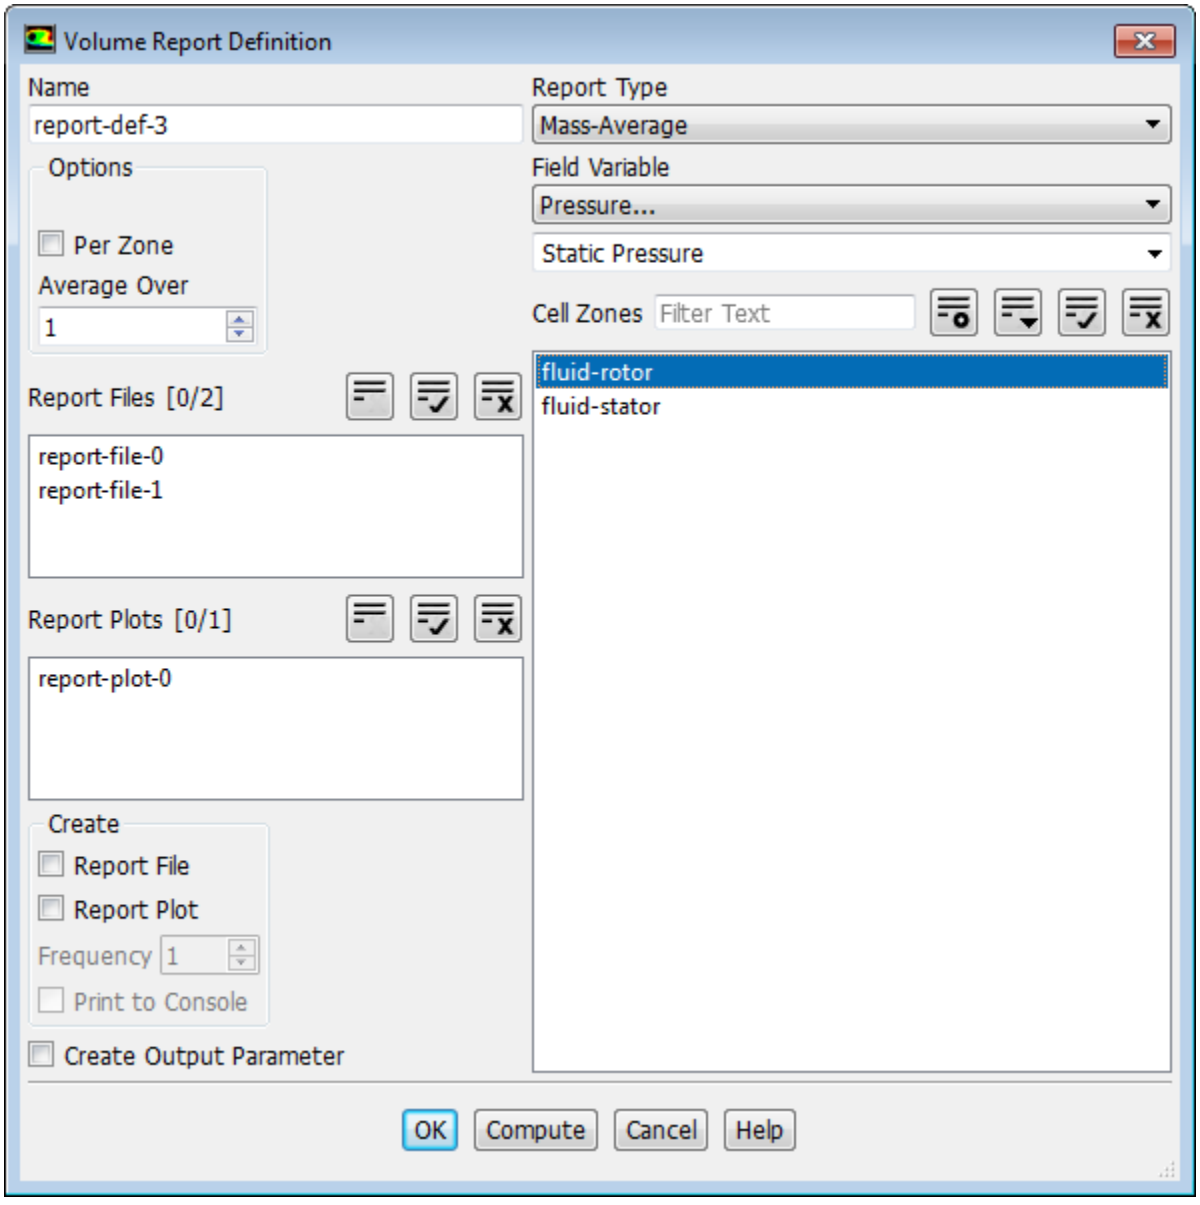
You can use the Figure 32.3: Volume Report Definition Dialog Box (p. 1892) to create volume report definitions. There are many different types of volume reports that you can create, including:

- Volume (non-field based)
- Sum
- Sum*2π (only axi-symmetric)
- Max
- Min

- Volume Integral
- Volume Average
- Mass Integral
- Mass Average
- Mass (non-field based)

Solving → Reports → Definitions → New → Volume Report

Figure 32.3: Volume Report Definition Dialog Box



The common steps for creating a volume report definition are covered in Creating Report Definitions (p. 1886), and the volume report definition-specific steps are as follows:

1. If you want the value reported on individual wall zones rather than the net results from a group of wall zones, enable the **Per Zone** option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Choose the integration method for the volume report definition by selecting **Volume**, **Sum**, **Sum*2Pi** (2D axisymmetric cases only), **Max**, **Min**, **Volume Integral**, **Volume-Average**, **Mass Integral**, **Mass-Average**, or **Mass** in the **Report Type** drop-down list. These methods are described in Volume Integration (p. 1922).

3. Specify the variable or function to be integrated in the **Field Variable** drop-down list. First select the desired category in the upper drop-down list. You can then select one of the related quantities in the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

4. Select the **Cell Zones** where you want Fluent to evaluate the specified variable.

5. Click **OK** to create the report definition and close the dialog box.

32.2.1.3. Force and Moment Report definitions

Monitoring force coefficients can be useful when you are calculating external aerodynamics, for example, and are especially interested in the lift coefficient. By monitoring these values you may also be able to stop the calculation early and reduce the processing time, as sometimes the force and moment coefficients converge before the residuals have decreased three orders of magnitude. (In such an instance, you should be sure to check the mass flow rate and heat transfer rate as well, to ensure that the mass and energy are being suitably conserved. This is accomplished using either the Figure 32.4: Drag Report Definition Dialog Box (p. 1894), the Figure 32.5: Lift Report Definition Dialog Box (p. 1895), or the Figure 32.6: Moment Report Definition Dialog Box (p. 1896)).

To begin setting up force or moment report definitions, first enter appropriate values in the **Reference Values** task page, as described in Reference Values (p. 1924). The relevant values include the following:

- The force coefficients use the reference area, density, and velocity.
- The moment coefficients use the reference area, density, velocity and length.

For information about how these coefficients are calculated, see Computing Forces, Moments, and the Center of Pressure in the Fluent Theory Guide.

Tip

You can have Fluent report unscaled force values by selecting **Drag Force** or **Lift Force** in the **Report Output Type** group box of the **Drag Report Definition** or **Lift Report Definition** dialog boxes, respectively.

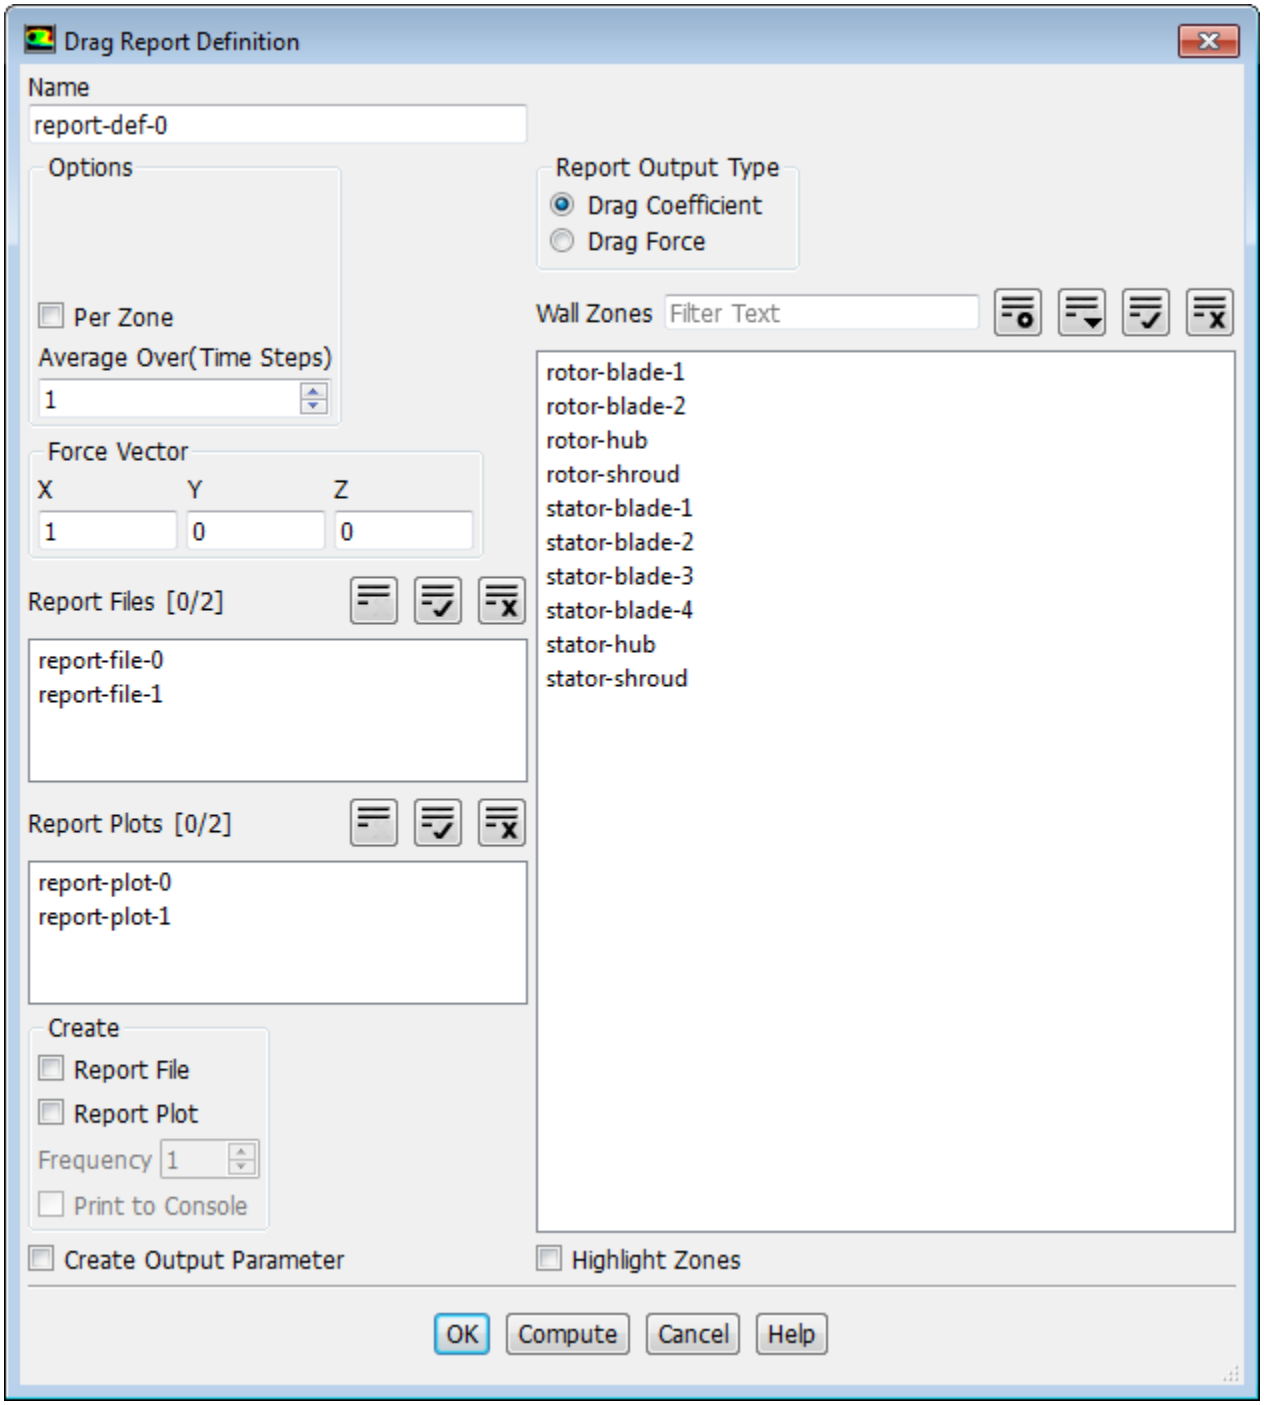
Next, open the appropriate dialog box through the **Solving** tab of the ribbon.

Solving → **Reports** → **Definitions** → **New** → **Force Report**

Select either **Drag...**, **Lift...**, or **Moment...** to open the Figure 32.4: Drag Report Definition Dialog Box (p. 1894), Figure 32.5: Lift Report Definition Dialog Box (p. 1895), and Figure 32.6: Moment Report Definition Dialog Box (p. 1896). Note that you can only access one of these report definition dialog boxes at a time, though multiple report definitions of the same type can be used during the simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.4: Drag Report Definition Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.5: Lift Report Definition Dialog Box

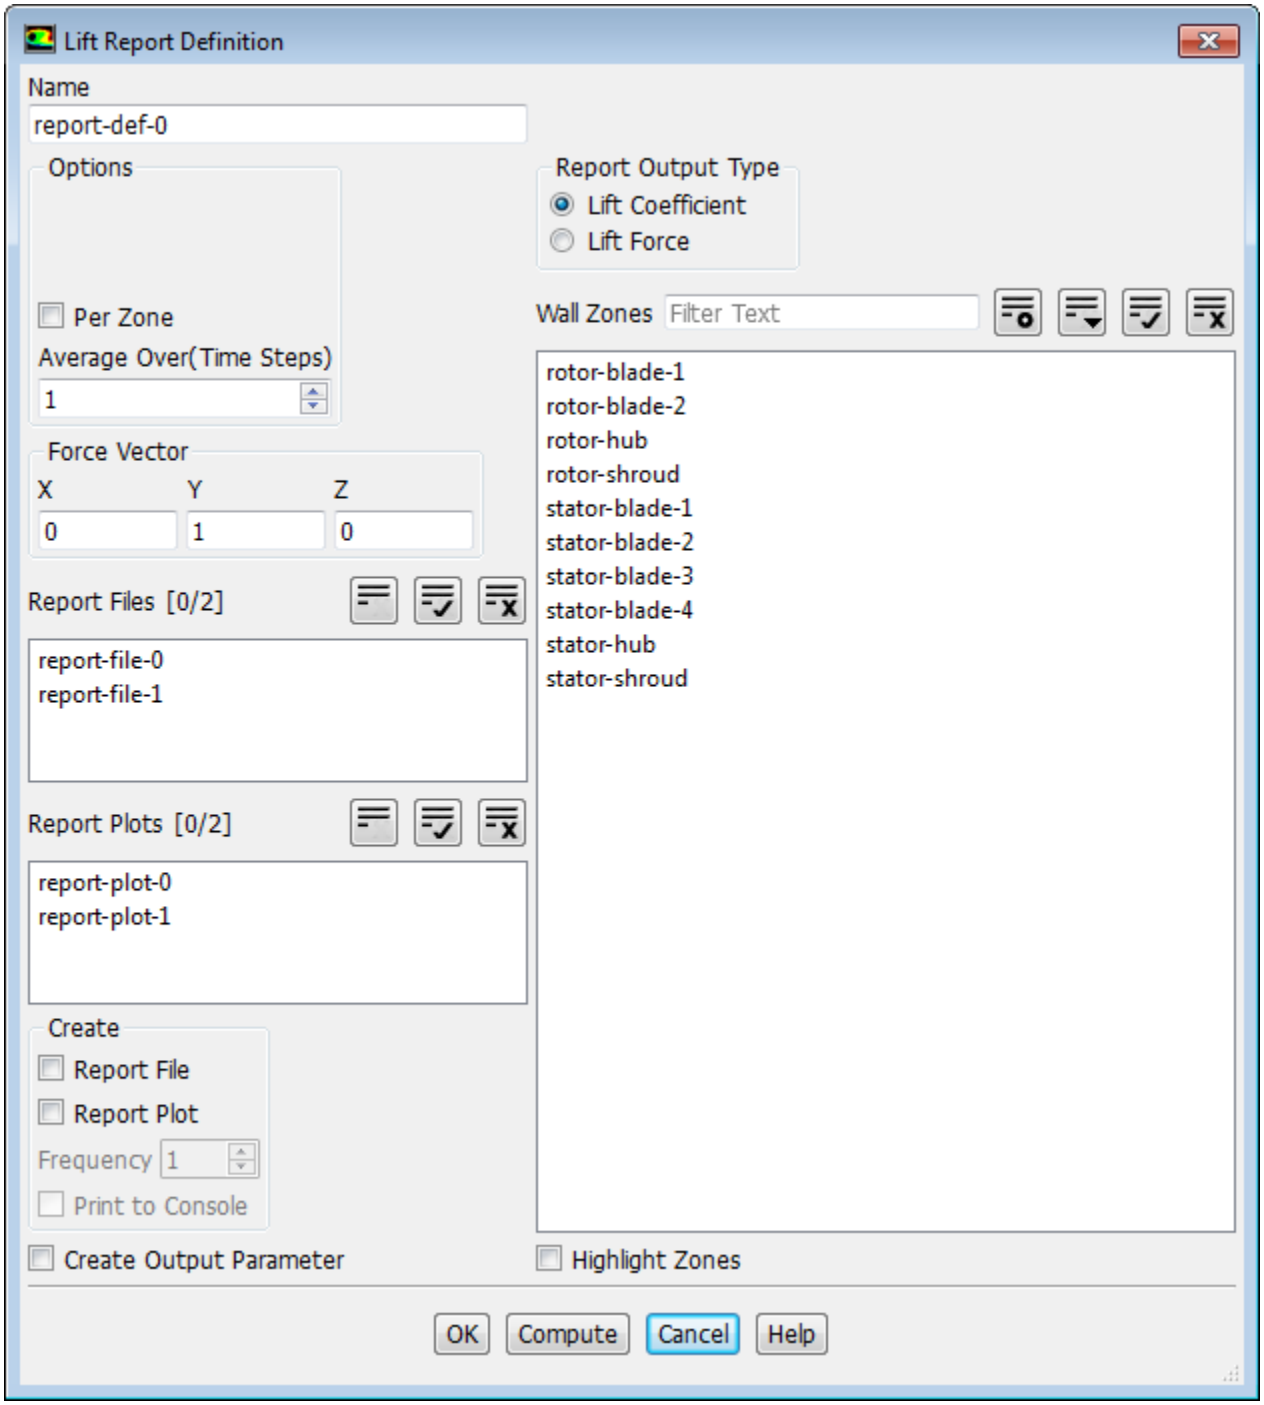


Figure 32.6: Moment Report Definition Dialog Box

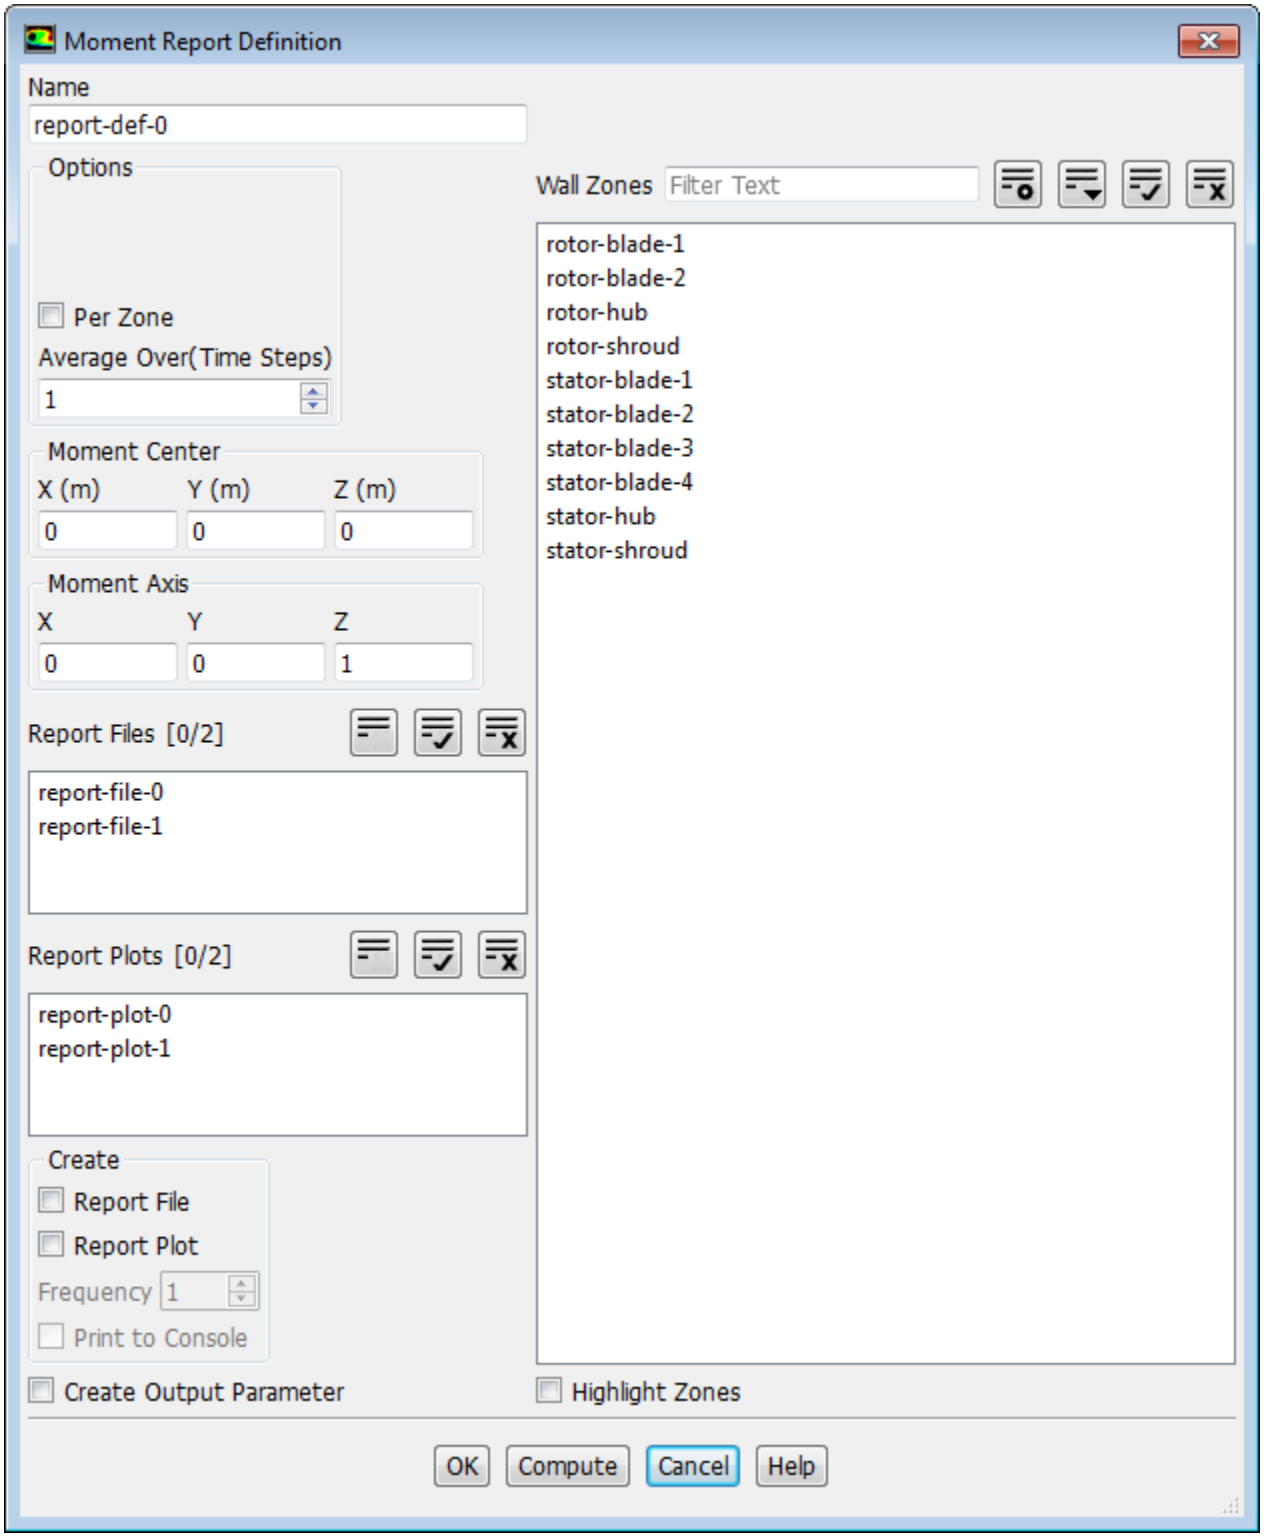


The common steps for creating a force or moment report definition are covered in Creating Report Definitions (p. 1886), and the force/moment report definition-specific steps are as follows:

1. If you want to report the force or moment coefficient data from individual wall zones rather than the net results from a group of wall zones, enable the **Per Zone** option.

2. Depending on the coefficient that will be monitored, perform one of the following steps:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In the **Drag Report Definition** or **Lift Report Definition** dialog box, enter the **X**, **Y**, and **Z** components of the **Force Vector** along which the forces will be computed. By default, the **Force Vector** for the drag coefficient is a unit vector in the x direction, whereas for the lift coefficient it is a unit vector in the y direction.

- In the **Moment Report Definition** dialog box, enter the Cartesian coordinates (**X**, **Y**, and **Z**) of the **Moment Center**, about which moments will be computed. The default **Moment Center** is (**0**, **0**, **0**). You also need to enter the **X**, **Y**, and **Z** components for the **Moment Axis**, along which the moment coefficient will be calculated. By default, the **Moment Axis** is defined as a unit vector in the z direction.

3. Select the appropriate wall zone(s) for computation of the coefficient(s).

4. You have the option to highlight a selected boundary zone and have it displayed in the graphics window by enabling **Highlight Zone**.

5. Click **OK** to save the report definition settings.

6. If you need to revise the settings of a particular report definition after they have been saved, double-click the report definition in the tree.

32.2.1.4. Flux Report Definition

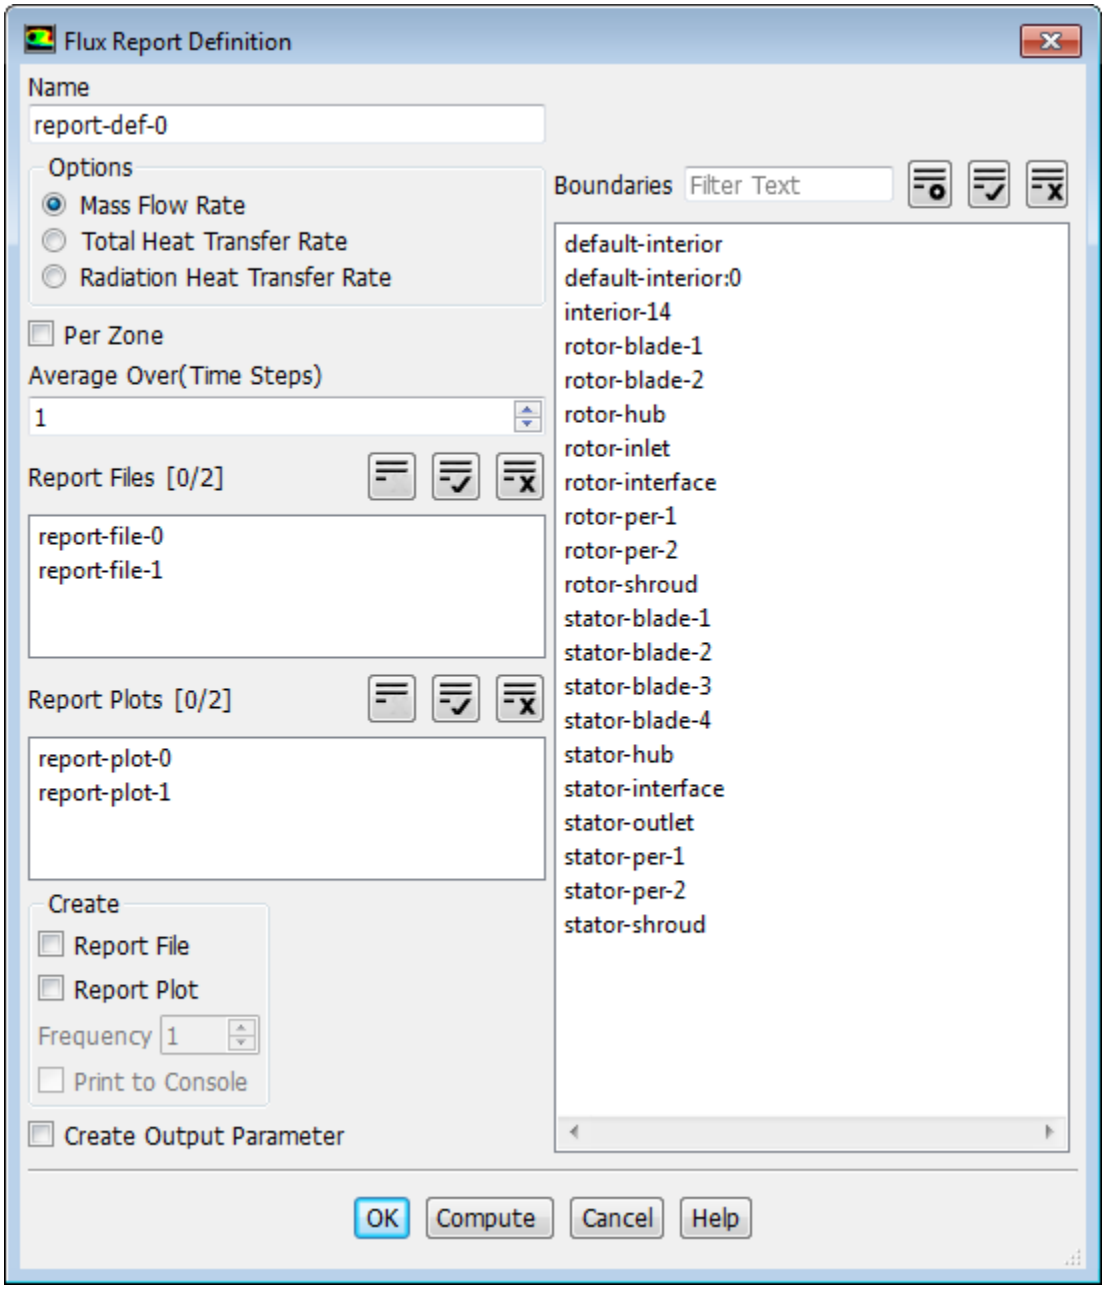
You can use the Figure 32.7: Flux Report Definition Dialog Box (p. 1898) to create flux report definitions. There are many different types of flux-based report definitions that you can create, including:

- Mass Flow Rate
- Total Heat Transfer Rate
- Total Sensible Heat Transfer Rate
- Radiation Heat Transfer Rate
- Film Mass Flow Rate
- Film Heat Transfer Rate
- DPM Mass Source
- DPM Enthalpy Source
- DPM Sensible Enthalpy Source

Solving → **Reports** → **Definitions** → **New** → **Flux Report**

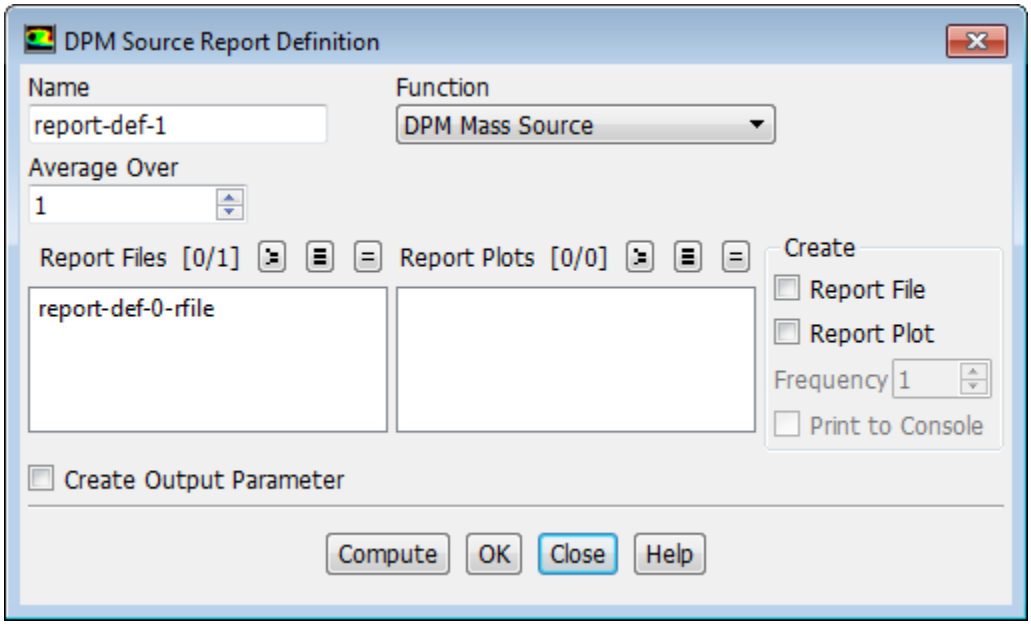
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.7: Flux Report Definition Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.8: DPM Source Report Definition Dialog Box



The common steps for creating a flux report definition are covered in Creating Report Definitions (p. 1886), and the flux report definition-specific steps are as follows:

1. Select or confirm the type of flux report.
2. Select the appropriate boundaries for the flux calculations.
3. Click **OK** to save the report definition settings.
4. If you need to revise the settings of a particular report definition after they have been saved, double-click the report definition in the tree.

For additional information on the available options for DPM source report definitions, see DPM Source Report Definition (p. 2690) in the reference guide.

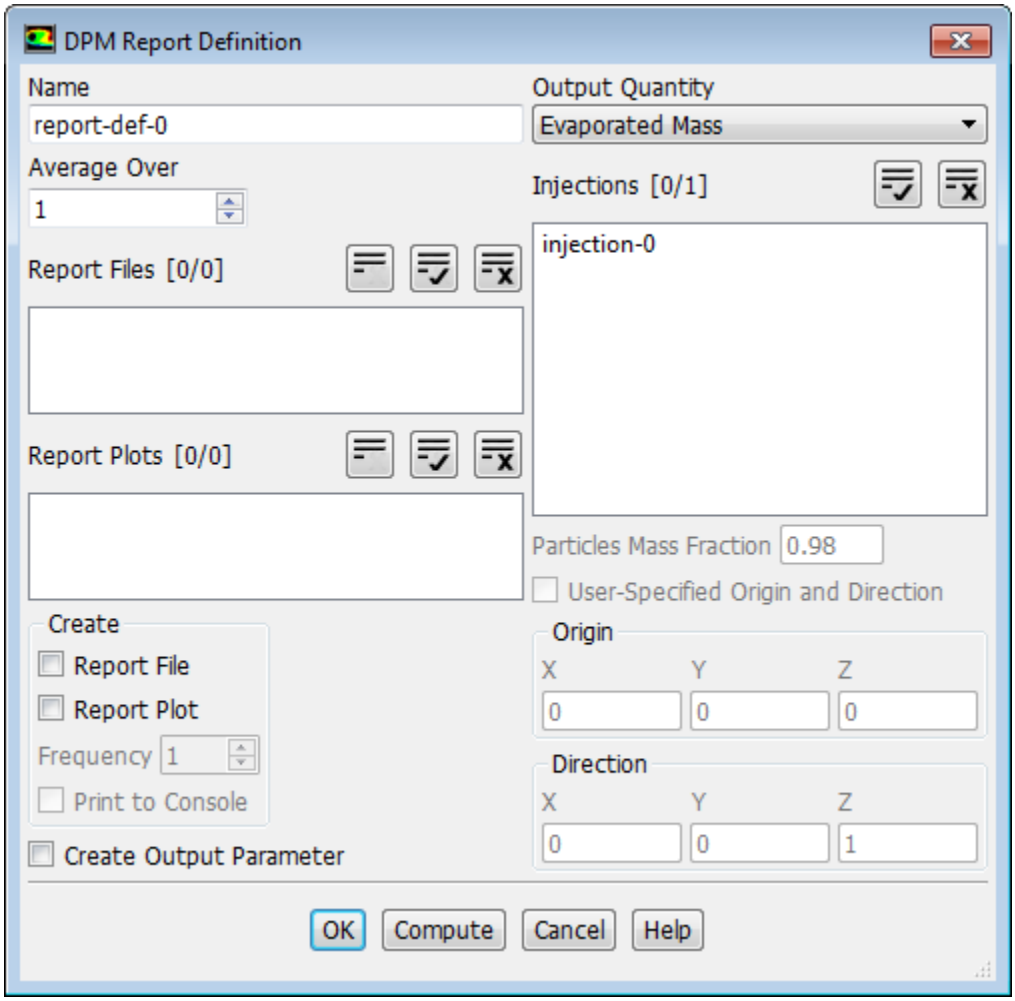
32.2.1.5. DPM Report Definition

You can use the DPM Report Definition dialog box to create DPM report definitions. The following types of DPM reports are available:

- Injected Mass (*unsteady particle tracking only*)
- Mass in Domain (*unsteady particle tracking only*)
- Escaped Mass
- Evaporated Mass
- Penetration Length (*unsteady particle tracking only*)

Solving → Reports → Definitions → New → DPM Report

Figure 32.9: DPM Report Definition Dialog Box



The common steps for creating a DPM report definition are covered in Creating Report Definitions (p. 1886), and the DPM report definition-specific steps are as follows:

1. Select or confirm the type of DPM report.

2. For the **Escaped Mass** report, if you want to have the escaped mass calculated per injection, enable the text command `report/dpm-zone-summaries-per-injection`.

   The **Injections** selection list will then appear in the **DPM Report Definition** dialog box.

3. From the **Injections** list, select the appropriate injections for the DPM report.

   Note

   For the **Escaped Mass** report, this step is relevant only if you have enabled the calculation of the escaped mass per injection.

4. For the **Escaped Mass** report, select the boundary(s) where the injected particles exit the domain from the **Boundaries** selection list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. For the **Penetration Length** report, you can specify the **Particles Mass Fraction**. You can also enable **User-Specified Origin and Direction** to specify those coordinates.

6. For unsteady particle tracking, you can select **Show Mass Flow/Change Rate** (default) for the **Injected Mass**, **Mass in Domain**, **Escaped Mass**, and **Evaporated Mass** reports if you want to create a report for the mass flow rate rather than the total mass.

7. Click **OK** to save the report definition settings.

8. If you need to revise the settings of a particular report definition after they have been saved, double-click the report definition in the tree.

Important

For unsteady particle tracking, if you want to select one or more injection(s) for any **Escaped Mass** report, you must enable the `report/dpm-zone-summaries-per-injection` text command before the first particles are injected; otherwise, some of the reported values may become inconsistent.

For additional information on the available options, see the DPM Report Definition Dialog Box (p. 2687) in the reference guide.

32.2.1.6. User Defined Report Definition

User defined report definitions allow you to create functions that return values that can be plotted, printed, written, or used in other expressions. User defined report definitions can also be used in the **Convergence Conditions** (Convergence Conditions (p. 1635)).

Creating a user defined report definition is a two step process:

1. Create a user defined report definition function.

2. Hook the user defined report definition function to the user defined report definition.

32.2.1.6.1. User Defined Report Definition Function

User defined report definition functions are defined with the `DEFINE_REPORT_DEFINITION_FN` macro, which takes the function name as the argument. The function must return a real value. Once written, it should be compiled and loaded the same way as other user-defined functions, see Interpreting and Compiling UDFs in the *Fluent Customization Manual* for more information.

The function body should be constructed similarly to any C function that returns a real value. Any valid C code can be included in the function body.

`DEFINE_REPORT_DEFINITION_FN` can use all of the APIs available for other user-defined functions, including:

- Last evaluated values of all report definitions.

- Current values of all input parameters that have been set to be used inside user-defined functions.

See `DEFINE_REPORT_DEFINITION_FN` in the *Fluent Customization Manual* for information on writing user defined report definition functions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

32.2.1.6.2. User Defined Report Definition Function Hooking

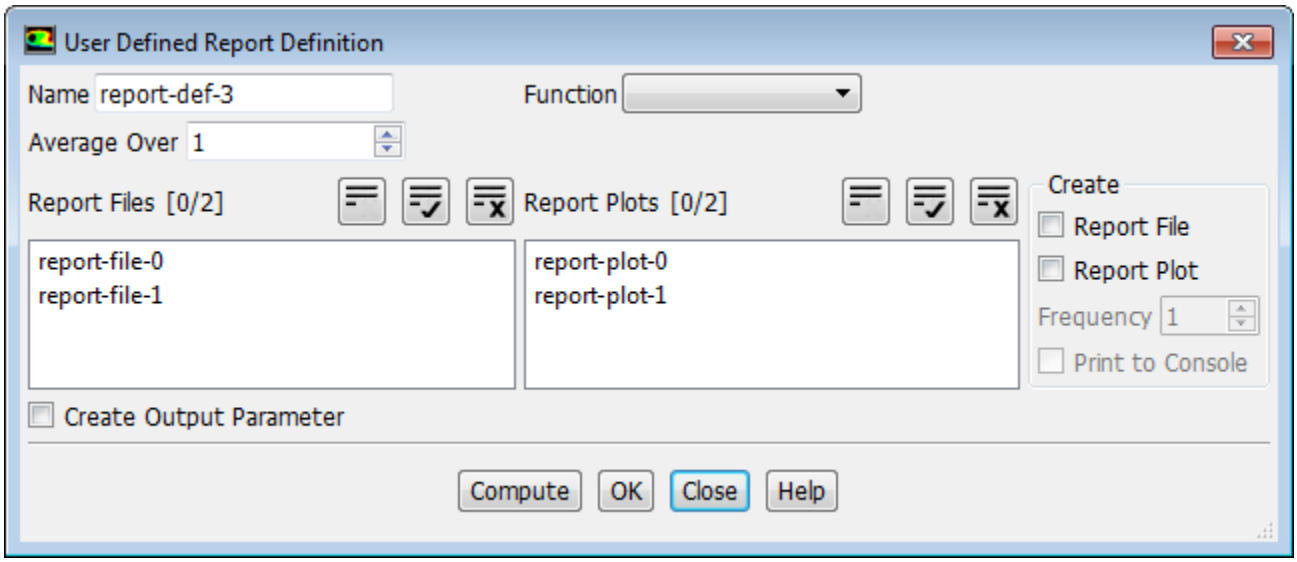
With the user defined report definition function written, you must hook this function to the user defined report definition.

The common steps for creating a user defined report definition are covered in Creating Report Definitions (p. 1886), and the user defined report definition-specific steps are as follows:

1. Open the **User Defined Report definition** dialog box.

   Solution → Report Definitions → New → User Defined

   Figure 32.10: User Defined Report Definition Dialog Box



2. Select your function from the **Function** drop-down list.

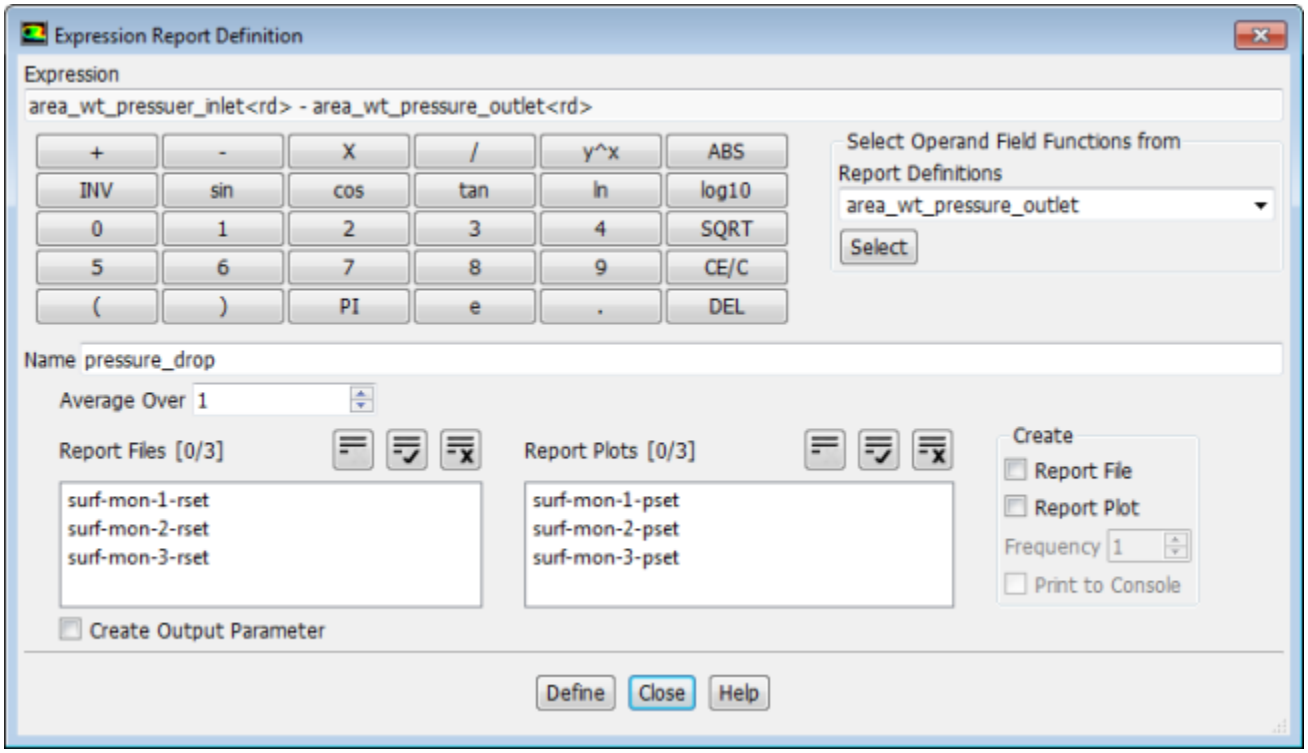
32.2.1.7. Expression Report Definition

You can create expressions from report definitions, allowing you to combine report definitions with mathematical operators to create a new report definition that can be written or plotted. For example, you can create a pressure-drop report for the difference in area-weighted pressures between an inlet and an outlet.

Solving → Reports → Definitions → New → Expression

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.11: Expression Report Definition Dialog Box



The common steps for creating an expression report definition are covered in Creating Report Definitions (p. 1886), and the expression report definition-specific steps are as follows:

1. Create the **Report Definition**(s) that you will use to create an **Expression**.
2. Use the calculator buttons to add functions and operators to the expression. Select report definitions from the **Report Definitions** drop-down list and click **Select** to add them to the expression formula.
3. Click **Define** to create the expression report definition.

Note

Expression report definitions cannot be copied.

32.2.2. Report Files and Report Plots

Report Files and **Report Plots** are collections of report definitions that are written to a single file (report file) or plotted to a graphics window (report plot) at specified intervals. In steady-state cases, report files are evaluated at the specified iteration, whereas in transient cases you have the option to specify the evaluation frequency based on iterations or timesteps.

*Report definitions in the same **Report Plot** must have the same units.*

Report Files Format:

```
"<report-file-name>"
"Iteration"|"Timestep" "<first-report-def-name> etc.."
("Iteration"|"Timestep" "<report-def-1-name>" "<report-def-2-name>"...)
<Iteration/Timestep> <report-def-1-value> <report-def-2-value>...
```

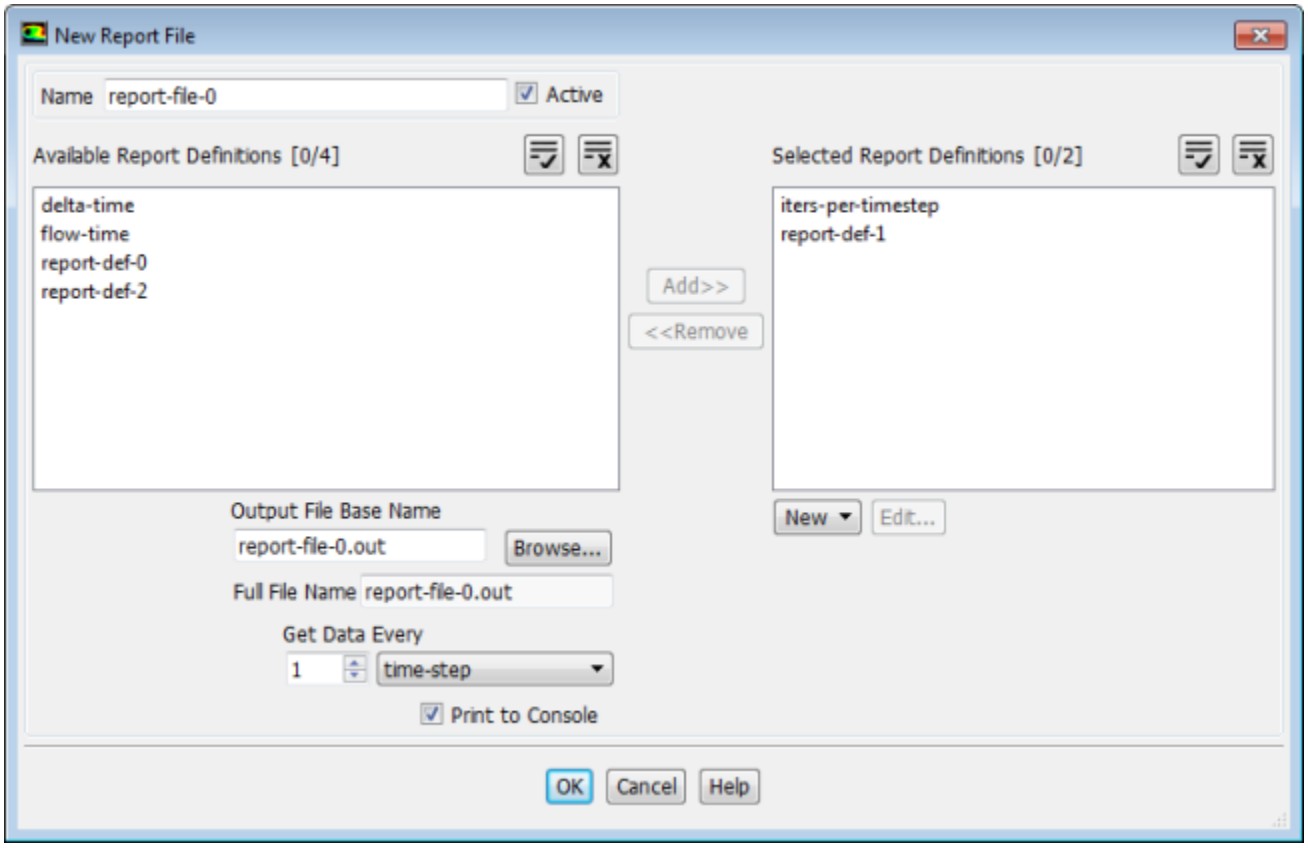
Report definitions included in a report plot are plotted in the specified window at the specified frequency. It is possible to plot the same report in multiple windows. Both report plots and report files provide the option to print to the console. You can deactivate the writing and plotting of individual report files and plots for a particular calculation; deactivated report files and plots can be re-activated at a later time.

32.2.2.1. Creating Report Files

In order to create a report file you must have first created a report definition.

Solution → Monitors → Report Files → New...

Figure 32.12: New Report File Dialog Box



1. Provide a name for how you want this report file to appear in the Fluent tree.

   *You have the option to deactivate the writing of this report file by de-selecting the **Active** check box to the right of the **Name**.*

2. Select one or more report definitions from **Available Report Defnitions** and click **Add>>**, to specify the reports you want written to the same file.

3. Provide an appropriate name in the **Output File Base Name** text box. The **Full File Name** that appears below the **Output File Base Name** field is created with a run index and iteration/time step index, appended to the base name.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Specify the frequency at which you want the report definitions written to the file.

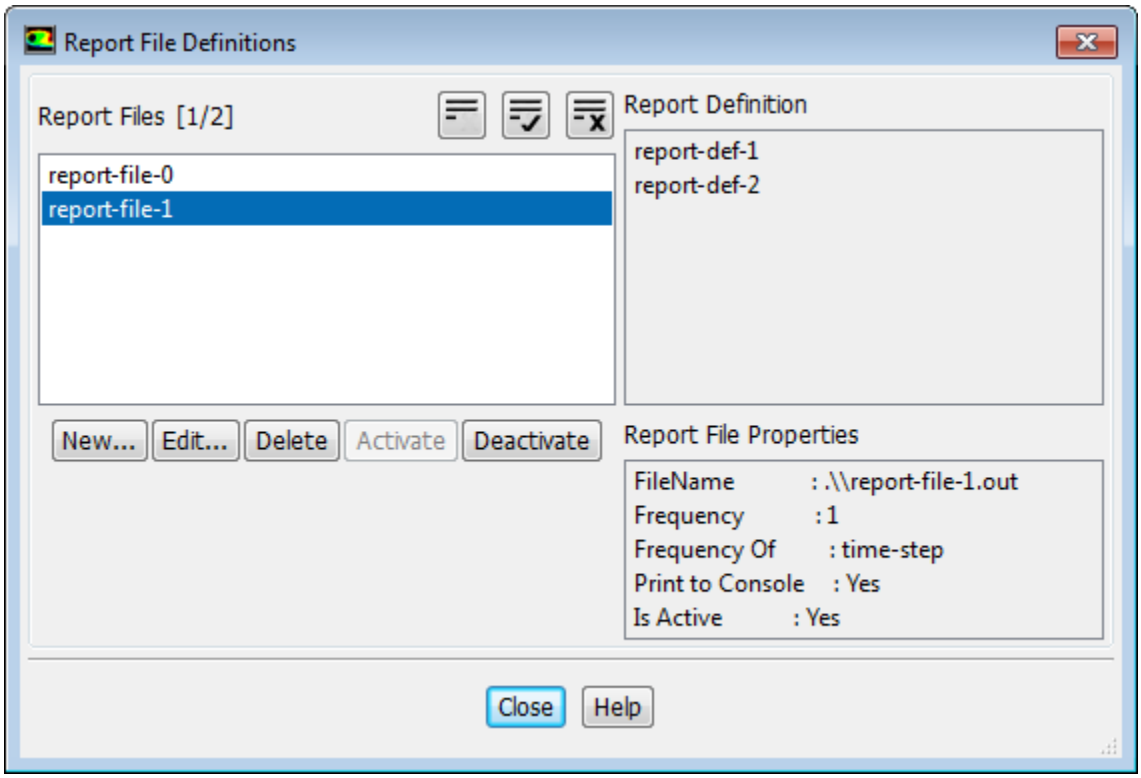
> **Note**
>
> In a transient simulation, If you specify an **Average Over** value in a report definition, you must set **Get Data Every** to **time-step**. If you set **Get Data Every** to **iteration**, Fluent will use the instantaneous value of the report definition.

5. Click **OK** to save the new report file.

You have the option to view—and edit —properties of report files that you created previously by selecting **Edit...** when you right-click **Report Files** in the tree, which opens the Figure 32.13: Report File Definitions Dialog Box (p. 1905).

Note that you can also right-click an individual report definition to modify it directly.

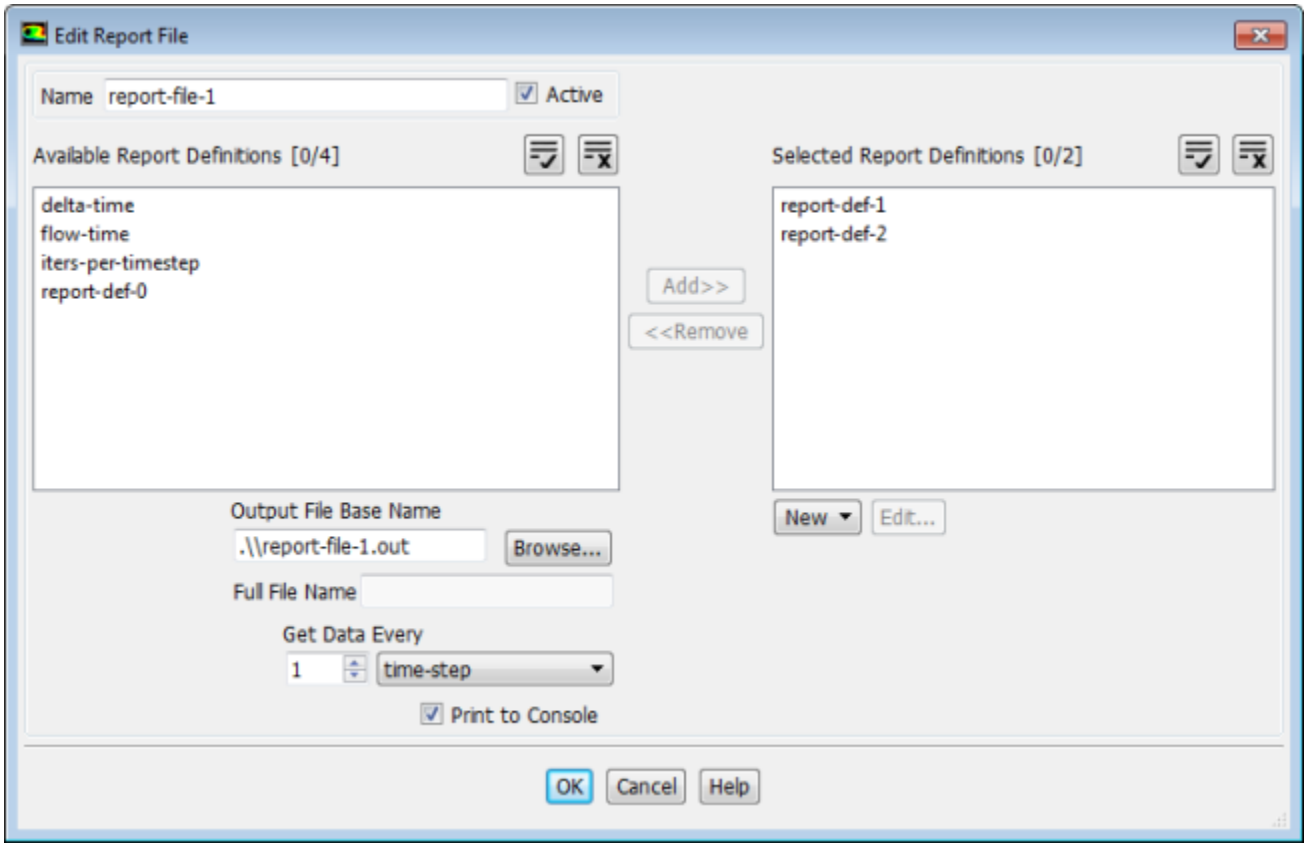
Figure 32.13: Report File Definitions Dialog Box



Selecting a report file to modify opens the Figure 32.14: Edit Report File Dialog Box (p. 1906).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.14: Edit Report File Dialog Box



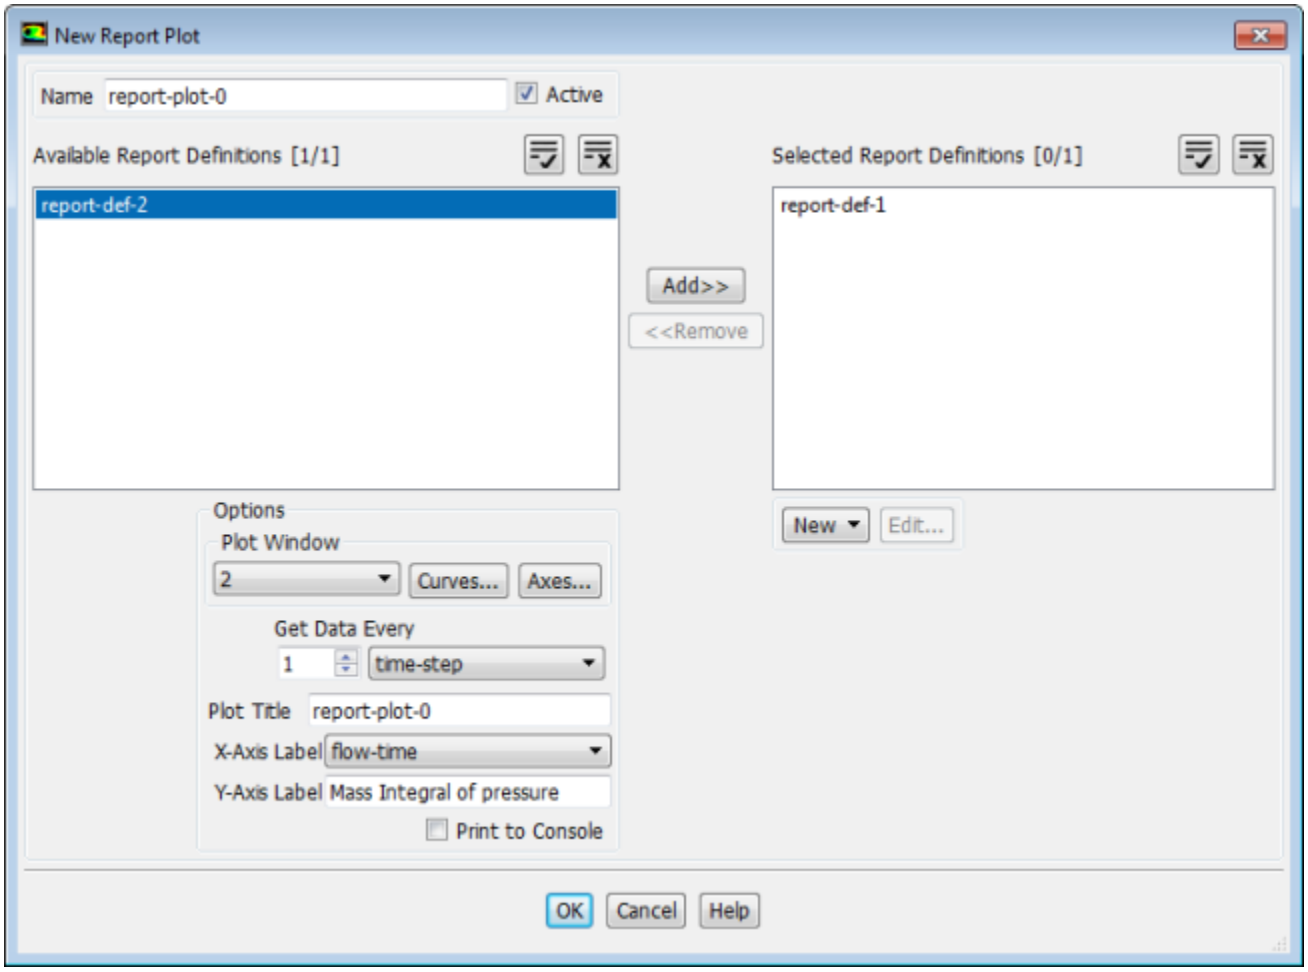
32.2.2.2. Creating Report Plots

In order to create a report plot you must have first created a report definition.

Solution → Monitors → Report Plots → New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.15: New Report Plot Dialog Box



1. Provide a name for how you want this report plot to appear in the Fluent tree.

   *You have the option to deactivate the plotting of this report plot by de-selecting the **Active** check box to the right of the **Name**.*

2. Select one or more report definitions from **Available Report Defnitions** and click **Add>>**, to specify the reports you want plotted in the same window.

3. Provide an appropriate names in the **Plot Title** and **Y-Axis Label** group boxes.

4. Specify the frequency at which you want the report definitions plotted to the specified window.

   Note

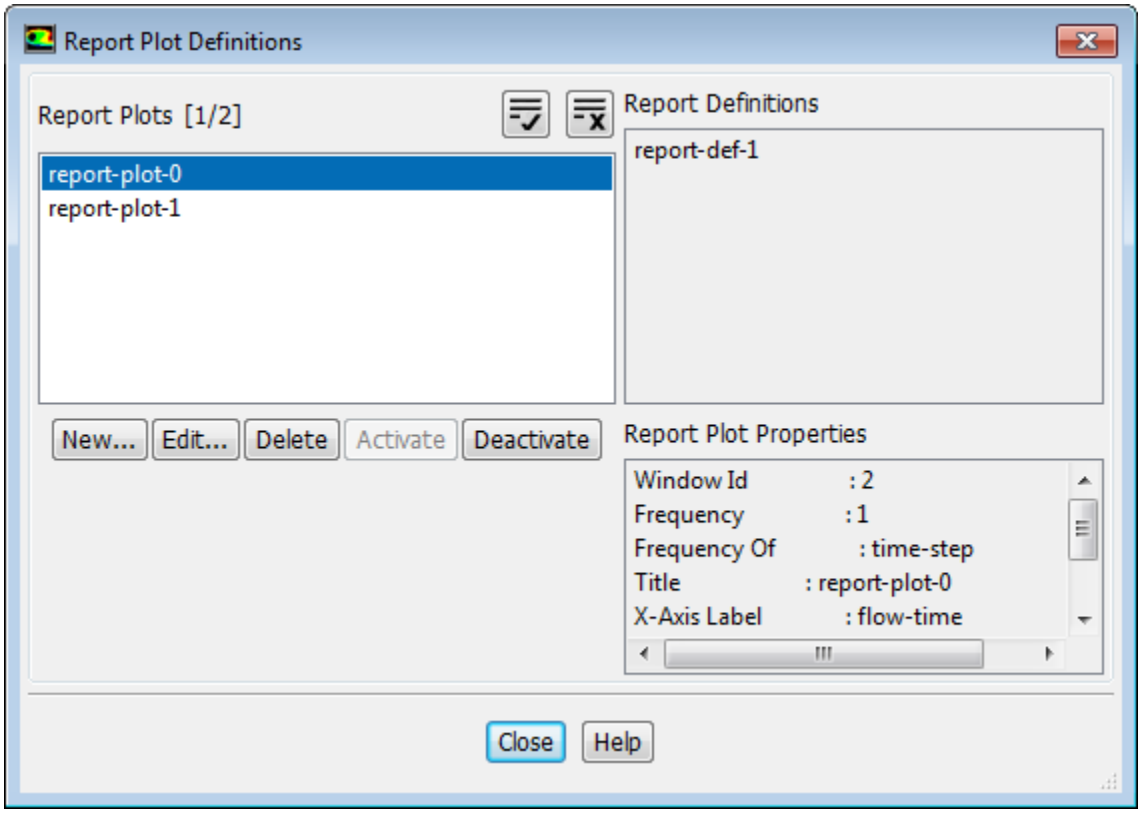
   In a transient simulation, If you specify an **Average Over** value in a report definition, you must set **Get Data Every** to **time-step**. If you set **Get Data Every** to **iteration**, Fluent will use the instantaneous value of the report definition.

5. Click **OK** to save the new report plot.

You have the option to edit report plots that you created previously by selecting **Edit...** when you right-click **Report Plots** in the tree, which opens the Figure 32.16: Report Plot Definitions Dialog Box (p. 1908).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

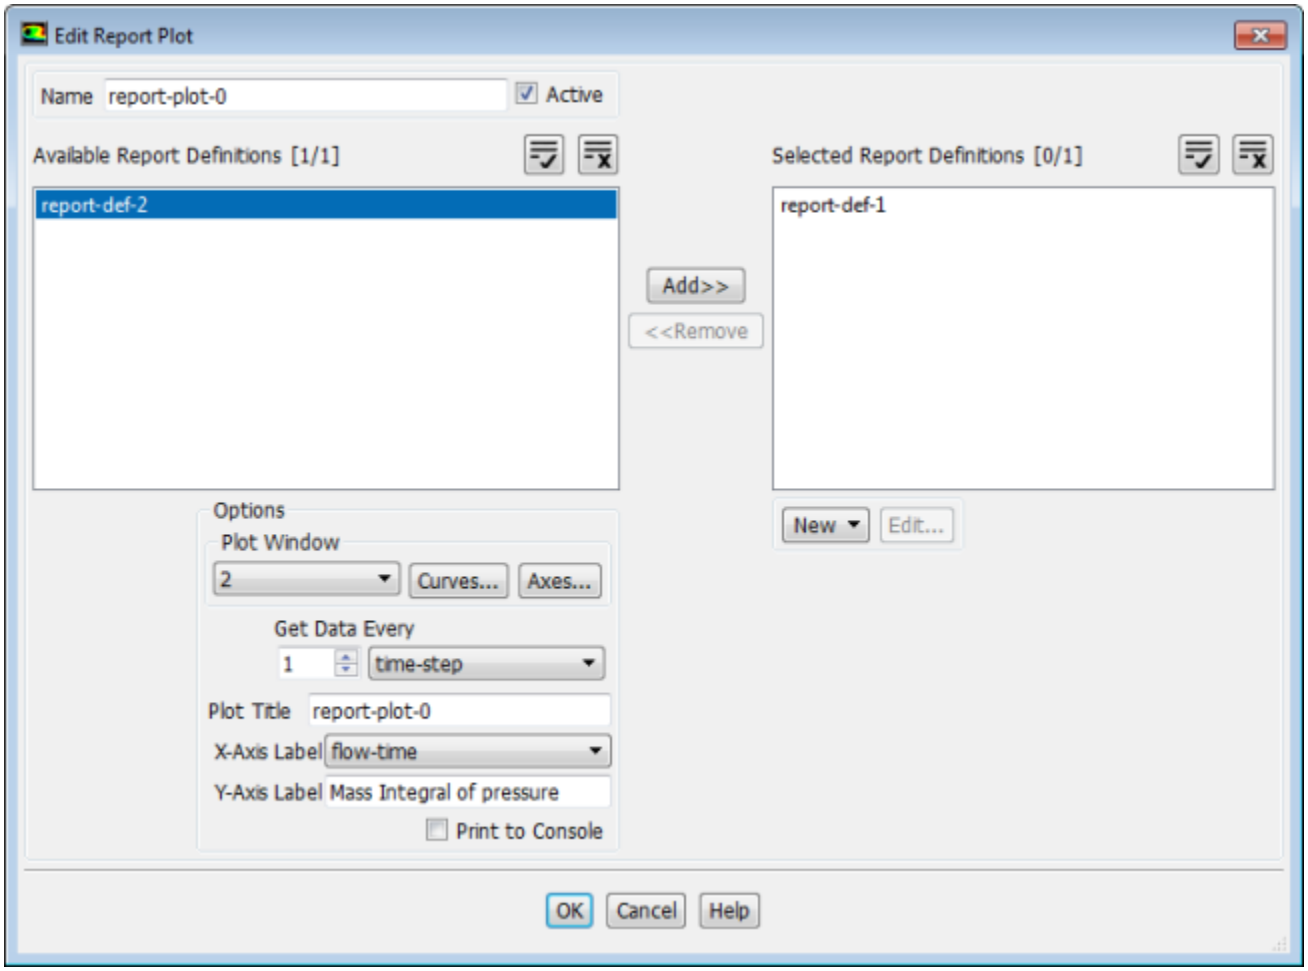
Figure 32.16: Report Plot Definitions Dialog Box



Selecting a report plot to modify opens the Figure 32.17: Edit Report Plot Dialog Box (p. 1909).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.17: Edit Report Plot Dialog Box



32.3. Creating Output Parameters

You can create output parameters, which allow you to compare reporting values for different cases, or include reporting values in the function minimized by the mesh morpher/optimizer. These are single values generated by a variety of reports:

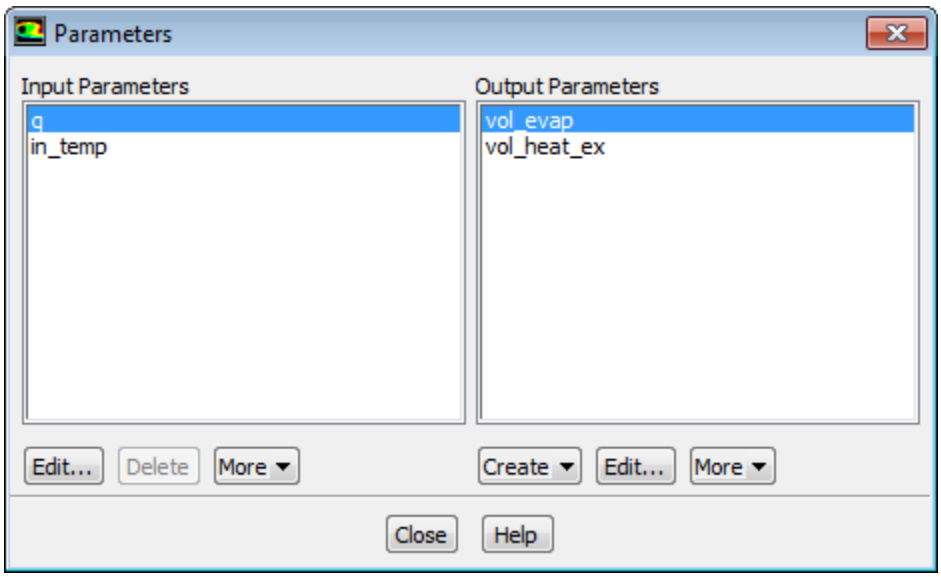
- Fluxes (Fluxes Through Boundaries (p. 1911))
- Forces (Forces on Boundaries (p. 1916))
- Surface integrals (Generating a Surface Integral Report (p. 1920))
- Volume integrals (Generating a Volume Integral Report (p. 1922))
- Surface report definitions (Surface Report definitions (p. 1889))
- Volume report definitions (Volume Report definitions (p. 1891))
- Drag report definitions (Force and Moment Report definitions (p. 1893))
- Lift report definitions(Force and Moment Report definitions (p. 1893))
- Moment report definitions(Force and Moment Report definitions (p. 1893))

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- User Defined report definitions(User Defined Report Definition (p. 1901))
- Expression report definitions (Expression Report Definition (p. 1902))

Click **Parameters...** in the **User Defined** ribbon tab (**Field Functions** group box) to open the Parameters Dialog Box (p. 2627), where a list of any previously created input parameters is available.

User Defined → Field Functions → Parameters...



The list of **Input Parameters** is populated after performing the steps outlined in Defining and Viewing Parameters (p. 243). The output parameters that you create will be listed under **Output Parameters**.

You can define the output parameters using the reporting dialog boxes, as described in Creating Report Definitions (p. 1886). The reporting dialog boxes are accessible **Definitions** drop-down list in the **Solving** ribbon tab (**Reports** group box). Clicking the **Create** drop-down list under **Output Parameters** in the **Parameters** dialog box allows you to select **From Report Definitions...**, which opens the Figure 32.1: Report Definitions Dialog Box (p. 1889). From there you can create any type of report definition.

Once you have saved your output parameters, you can modify their definitions by selecting the parameter in the **Output Parameters** list and clicking **Edit...**. This will open the report dialog box where you can make your changes.

In addition, you can select any of the following commands under the **More** drop-down list:

Delete
removes the selected output parameter from the list of **Output Parameters**.

Print to Console
reports values to the console window. If you select multiple output parameters, then the output includes values from multiple output parameters.

Print All to Console
outputs the values from all output parameters to the console window.

Write...
allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Write All...
prompts you for a file name and then writes the values for all of the output parameters to a file.

32.4. Fluxes Through Boundaries

This section contains information about generating a flux report. For more background information, see Fluxes Through Boundaries in the Theory Guide .

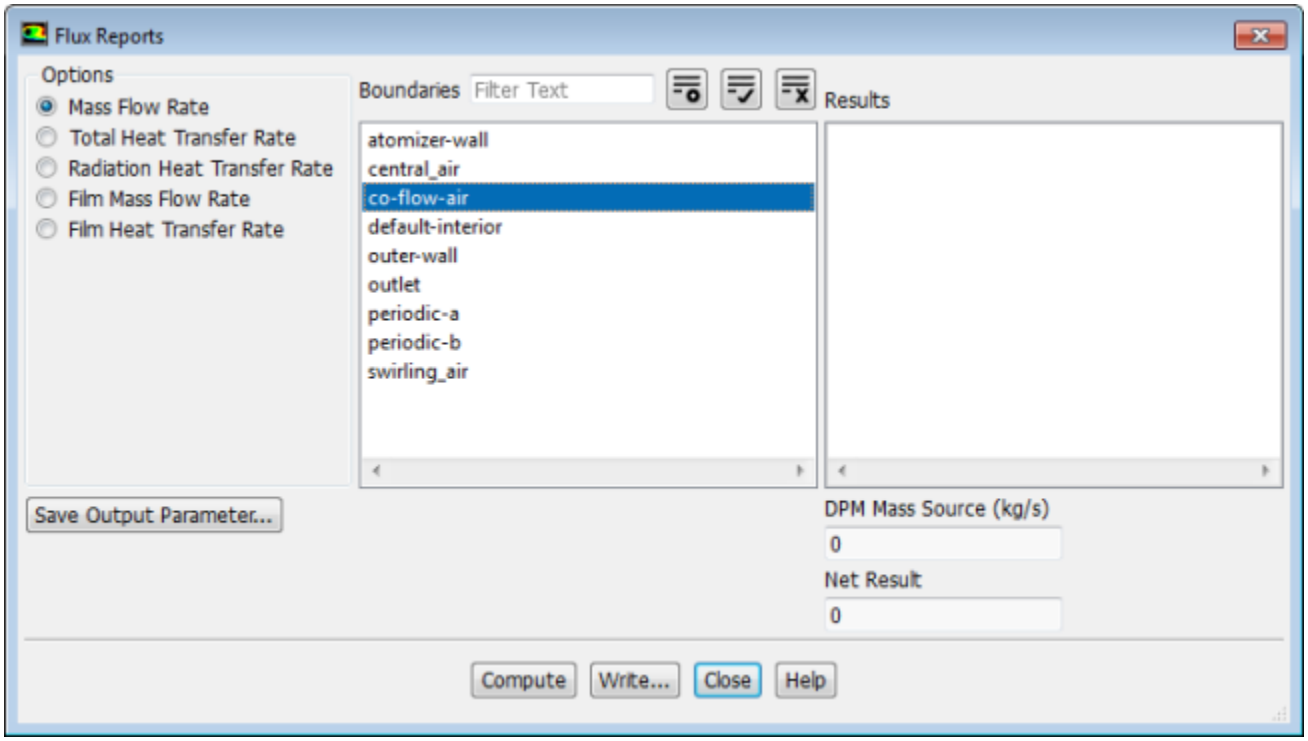
For additional information, see the following sections:
32.4.1. Generating a Flux Report
32.4.2. Flux Reporting for Reacting Flows

32.4.1. Generating a Flux Report

To obtain a report of mass flow rate, total heat transfer rate, total sensible heat transfer rate, or radiation heat transfer rate on selected boundary zones, use the Flux Reports Dialog Box (p. 2613) (Figure 32.18: The Flux Reports Dialog Box (p. 1911)).

Results → Reports → Fluxes Edit...

Figure 32.18: The Flux Reports Dialog Box



The steps for generating the report are as follows:

1. Specify which flux computation you are interested in by selecting one of the following under **Options**:

   - **Mass Flow Rate**
   - **Total Heat Transfer Rate**
   - **Total Sensible Heat Transfer Rate**

- **Radiation Heat Transfer Rate**
- **Film Mass Flow Rate** (available as an option only when the Eulerian Wall Film model is enabled—see Modeling Eulerian Wall Films (p. 1535))
- **Film Heat Transfer Rate** (available as an option only when the Eulerian Wall Film model is enabled—see Modeling Eulerian Wall Films (p. 1535))

2. In the **Boundaries** list, choose the boundary zone(s) on which you want to report fluxes.

   You can use **Filter Text** entry box to filter the **Boundaries** list to show only the boundary zones that match the pattern you enter. For additional information on using the **Filter Text** entry box, see Filter Text Entry Boxes (p. 15).

3. To create an output parameter for the reported value, click **Save Output Parameter...**. The Save Output Parameter Dialog Box (p. 2631) (Figure 32.19: The Save Output Parameter Dialog Box (p. 1912)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, parameter-1, parameter-2, and so on).

   Figure 32.19: The Save Output Parameter Dialog Box

   After the output parameter is created, it is listed in the Parameters Dialog Box (p. 2627), accessed via the **Parameters...** button in the Reports Task Page (p. 2611). You can create any number of output parameters of this report type.

   Note

   If you create an output parameter from a flux report and save the case and data (write), an equivalent report definition will be created when you read in the case file.

4. Click the **Compute** button to display the results of the selected flux computation for each selected boundary zone. The **Net Results** field will show the summation of the individual zone flux results.

Important

Additional steps must be taken prior to generating a flux report for an interior boundary zone that has the same fluid defined on either side. In such a case, the area vectors of the cell faces associated with the zone may have been automatically defined in an inconsistent manner when the mesh file was read into the solver. Since the flux for each individual cell

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

face is calculated with respect to its area vector, such an inconsistency leads to inaccurate results when the face fluxes are summed to calculate the total flux of the boundary zone.

To ensure accurate flux results for such an interior zone, you must orient the area vectors by changing the definition of the zone **Type** to **wall**. You should then change the **Type** back to **interior** and proceed to generate the flux report.

Note that the fluxes are reported exactly as computed by the solver. Therefore, they are inherently more accurate than those computed with the **Flow Rate** option in the Surface Integrals Dialog Box (p. 2616) (described in Surface Integration (p. 1920)).

32.4.2. Flux Reporting for Reacting Flows

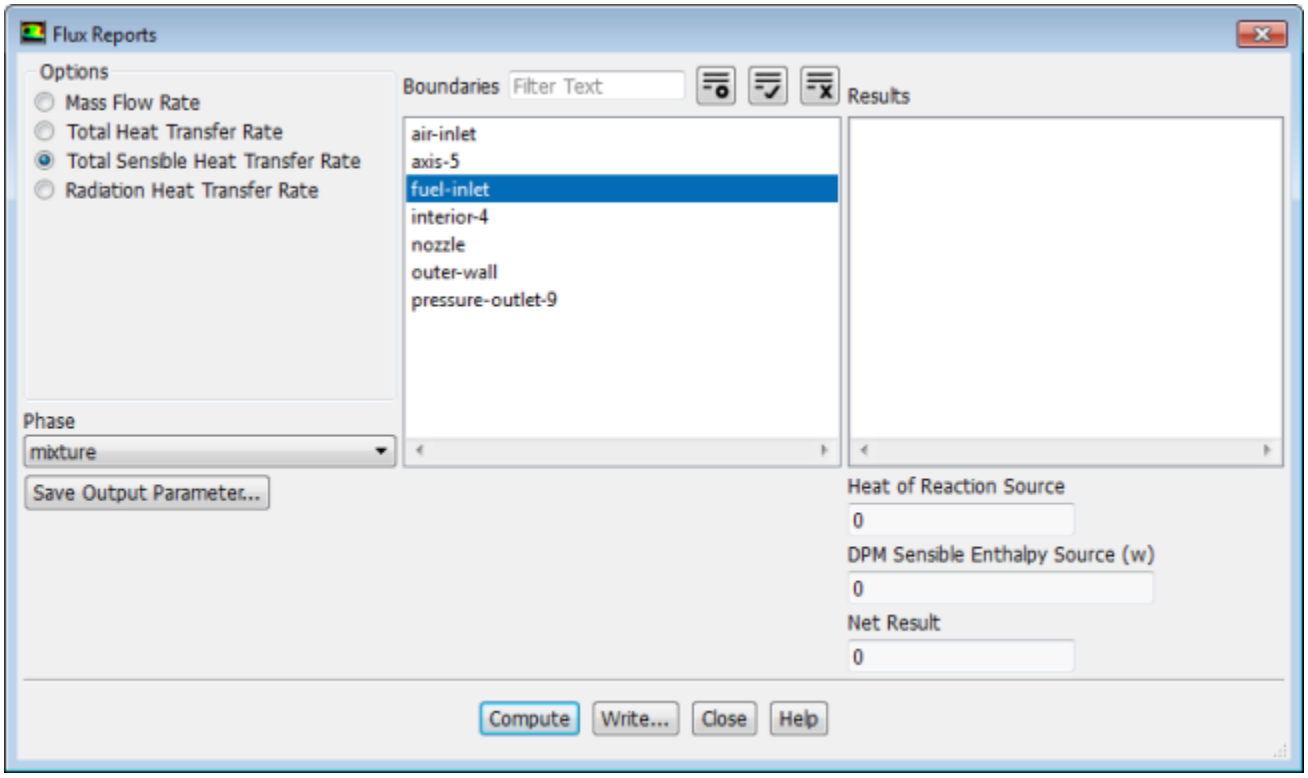
To report heat transfer for reacting flows, one of models in the Species Model Dialog Box (p. 2216) must be enabled for the **Total Sensible Heat Transfer Rate** option to appear in the Flux Reports Dialog Box (p. 2613). For reacting flows, ANSYS Fluent produces two kinds of reports that use a different treatment at the flow boundaries:

- **Total Heat Transfer Rate** reports the total enthalpy flux, which consists of the thermal enthalpy, plus the species formation enthalpy when **Volumetric Reactions** are enabled. The heat rate based on this definition is a conserved quantity in reacting flows. See Heat Transfer Theory in the Theory Guide for details.

- **Total Sensible Heat Transfer Rate** reports the total energy flux as defined in Equation 5.2 in the Theory Guide . Note that in reacting flows, this is not a conserved quantity and the addition or removal of heat due to the chemical reactions (Equation 5.10 in the Theory Guide) is reported separately in the **Heat of Reaction Source** field, as shown in Figure 32.20: The Flux Reports Dialog Box (p. 1914). If you have more than one reaction defined in your case, the **Heat of Reaction Source** reported is the sum of the heat for all reactions. For exothermic reactions the **Heat of Reaction Source** is reported as a positive quantity, while for endothermic reactions it will be a negative quantity.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.20: The Flux Reports Dialog Box



Important

Note that both the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options report a **Net Result**, which may be used as an indication of the energy balance for the case. In general, and if heat sources other than the heat of reaction and DPM are not included in your problem, the **Net Result** reported in both the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options should be a small number for a converged calculation. However, if a reacting case is not well converged for both energy and species transport equations, the **Net Result** reported in the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options may differ. In that case, you may consider iterating further to achieve a fully converged solution. In addition, refer to the sections that follow for special considerations when including particles, multiphase models, or other volumetric energy sources.

Important

Note that for the non-premixed and partially premixed models the **Heat of Reaction Source** is calculated as the difference of the net **Total Heat Transfer Rate** and the net **Total Sensible Heat Transfer Rate**. The **Heat of Reaction** field function is not available for the non-premixed and partially-premixed models.

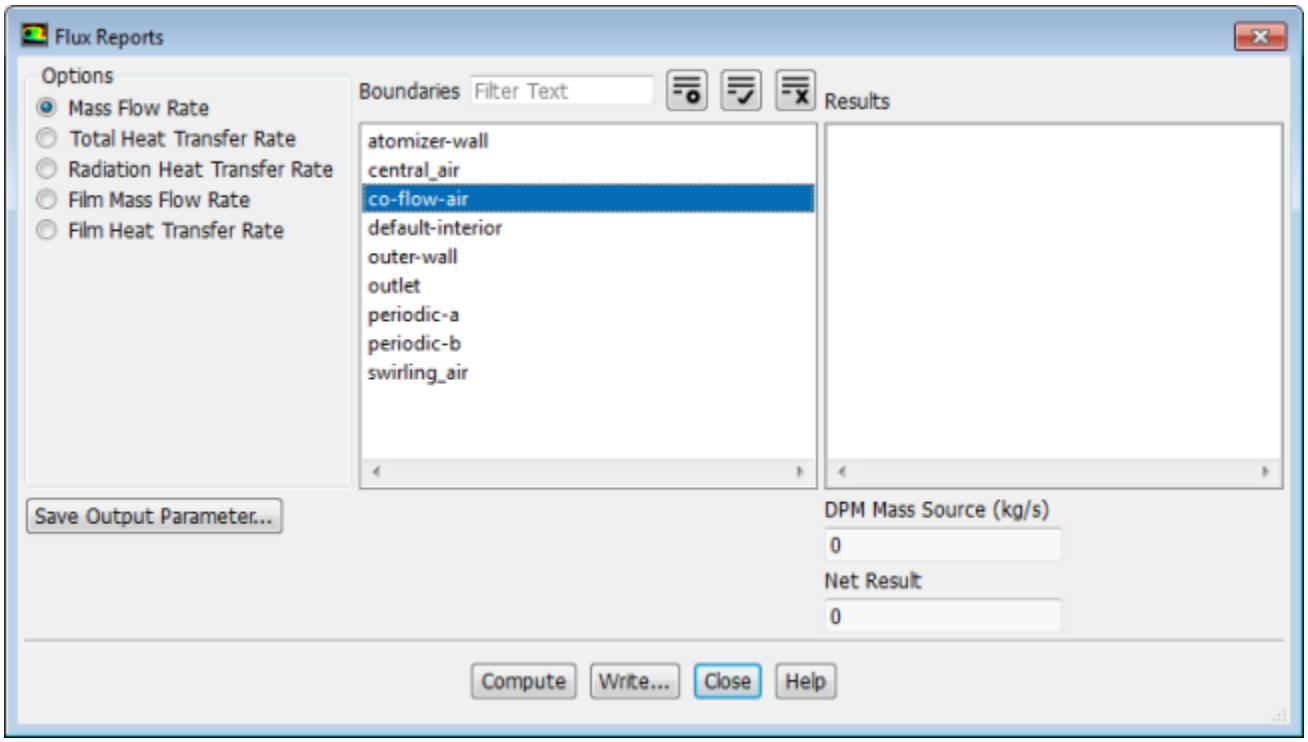
32.4.2.1. Flux Reporting with Particles

If you are using the discrete phase model (DPM), the contributions from the particle injections are reported separately and are included in the net mass and heat balance results. Consequently, the **Mass Flow Rate** report includes the **DPM Mass Source**, the **Total Heat Transfer Rate** report includes the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DPM Enthalpy Source, and the **Total Sensible Heat Transfer Rate** includes the **DPM Sensible Enthalpy Source** (Figure 32.21: The Flux Reports Dialog Box with DPM (p. 1915)).

Figure 32.21: The Flux Reports Dialog Box with DPM



Important

In the case of reacting flows with the DPM model, the **Heat of Reaction Source** entry reports the heat of all homogeneous reactions in the continuous phase, while the heat released or consumed due to particle reactions (e.g, char combustion) is reported in the **DPM Sensible Enthalpy Source** field.

32.4.2.2. Flux Reporting with Multiphase

If you are using any of the multiphase models, the mass or heat rates can be reported separately for each phase and for the mixture phase. Note that if your multiphase model includes mass or heat transfer processes between phases, the mass and heat transferred across the phases will be reported as an imbalance in the report of each phase. In order to check the overall balances for the multiphase cases you should select the mixture phase for your report. In that case, the report will include the sum of the fluxes and sources for all phases included in your model.

Finally, if you are solving a multiphase problem that includes chemical reactions, you should be aware of the following conventions when you are requesting a **Total Sensible Heat Transfer Rate** report:

- If you select one of the phases with gas phase chemical reactions, the **Heat of Reaction Source** will only include contributions from reactions in the particular phase.
- When you report the **Total Sensible Heat Transfer Rate** for the mixture phase, the **Heat of Reaction Source** entry will report the sum of the heat of reaction of all gas phase reactions in all phases plus the heat of any heterogeneous reactions that take place.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

32.4.2.3. Flux Reporting with Other Volumetric Sources

The reported mass and heat balances address the flow that enters or leaves the domain through boundaries and the contributions from DPM sources; they do not include the contributions from user-defined and other volumetric sources, such as the heat exchanged in the Heat Exchanger Model. For this reason, a mass or heat imbalance may be reported. In that case, and in a converged calculation, the reported imbalance will be equal to the volumetric source.

32.5. Forces on Boundaries

For wall zones that you select, you can compute and report the forces along a specified vector, the moments about a specified center and along a specified axis, and the coordinates of the center of pressure. This feature is useful for reporting, for instance, aerodynamic quantities such as lift, drag, and moment coefficients, as well as the center of pressure for an airfoil.

For additional information about forces, moments, and the center of pressure, see Computing Forces, Moments, and the Center of Pressure in the Theory Guide .

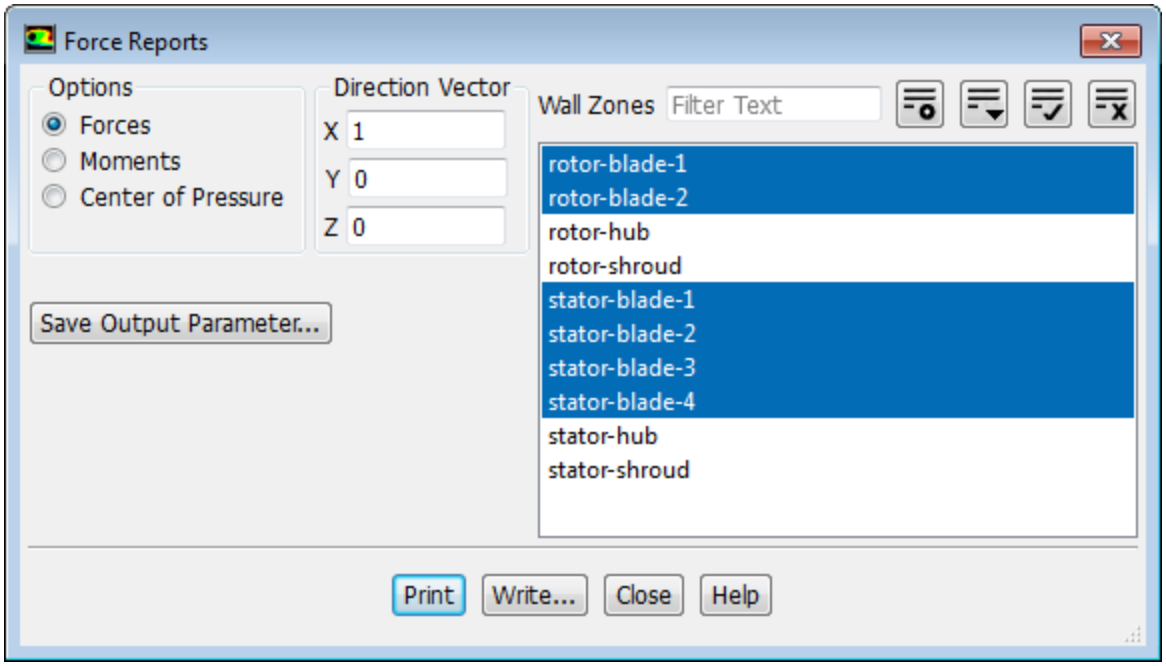
For additional information, see the following section:
32.5.1. Generating a Force, Moment, or Center of Pressure Report

32.5.1. Generating a Force, Moment, or Center of Pressure Report

To obtain a report (for selected wall zones) of forces along a specified vector, moments about a specified center and along a specified axis, or the center of pressure, use the Force Reports Dialog Box (p. 2614) (Figure 32.22: The Force Reports Dialog Box (p. 1916)).

Results → Reports → Forces Edit...

Figure 32.22: The Force Reports Dialog Box



The steps for generating the report are as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Specify the type of report in which you are interested by selecting **Forces**, **Moments**, or **Center of Pressure** from the **Options** list.

2. Define the settings associated with report you are generating:

   a. For a force report, enter the **X**, **Y**, and **Z** components of the **Force Vector** along which the forces will be computed.

   Important

   If F_x (the x-component of the force) is zero, then either the **Y** or **Z** coordinate can be fixed. If F_y is zero, then either the **X** or **Z** coordinate can be fixed. If F_z is zero, then either the **X** or **Y** coordinate can be fixed.

   b. For a moment report, enter the **X**, **Y**, and **Z** coordinates of the **Moment Center** about which the moments will be computed, as well as the **X**, **Y**, and **Z** components of the **Moment Axis** along which the moments will be computed.

   c. For a center of pressure report, define the line (for 2D geometries) or plane (for 3D geometries) on which you want to calculate the center of pressure. The line or plane must have one of its coordinate values fixed (for example, a line defined as $y=10$). Select the axis (**X**, **Y**, or **Z**) in the **Coordinate** group box, and then enter the fixed **Value**. See the example at the end of this section for further details.

3. In the **Wall Zones** list, select the wall zone(s) for which you want a report of the forces, moments, or pressure center.

4. To create an output parameter for the reported value, click **Save Output Parameter...**. The Save Output Parameter Dialog Box (p. 2631) (Figure 32.19: The Save Output Parameter Dialog Box (p. 1912)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, parameter-1, parameter-2, and so on).

   After the output parameter is created, it is listed in the Parameters Dialog Box (p. 2627). You can create any number of output parameters of this report type.

   Note

   If you create an output parameter from a force, moment, or center of pressure report and save the case and data (write), an equivalent report definition will be created when you read in the case file.

5. Click the **Print** button if you want the results displayed in the console window, or click **Write...** to save it to a file.

   If you selected **Forces** under **Options**, the pressure force, viscous force (if appropriate), total forces, pressure coefficient, viscous coefficient, and total coefficients for each selected wall zone will be displayed or saved.

   If you selected **Moments**, the pressure moments, viscous moments (if appropriate), total moments, pressure coefficient, viscous coefficient and total coefficients for the wall zones about the specified center will be displayed or saved. Additionally, the moments and coefficients in the direction of the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specified axis will be displayed or saved. The report will include the values for the individual wall zones, as well as the net values for all of the wall zones combined. See Computing Forces, Moments, and the Center of Pressure in the Theory Guide for details about computing forces and moments.

If you selected **Center of Pressure**, then ANSYS Fluent displays or saves the coordinates about which the moment is zero.

Important

You cannot save your output parameter if **Center of Pressure** is selected; **Center of Pressure** is not available as an output parameter since it is a set of coordinates.

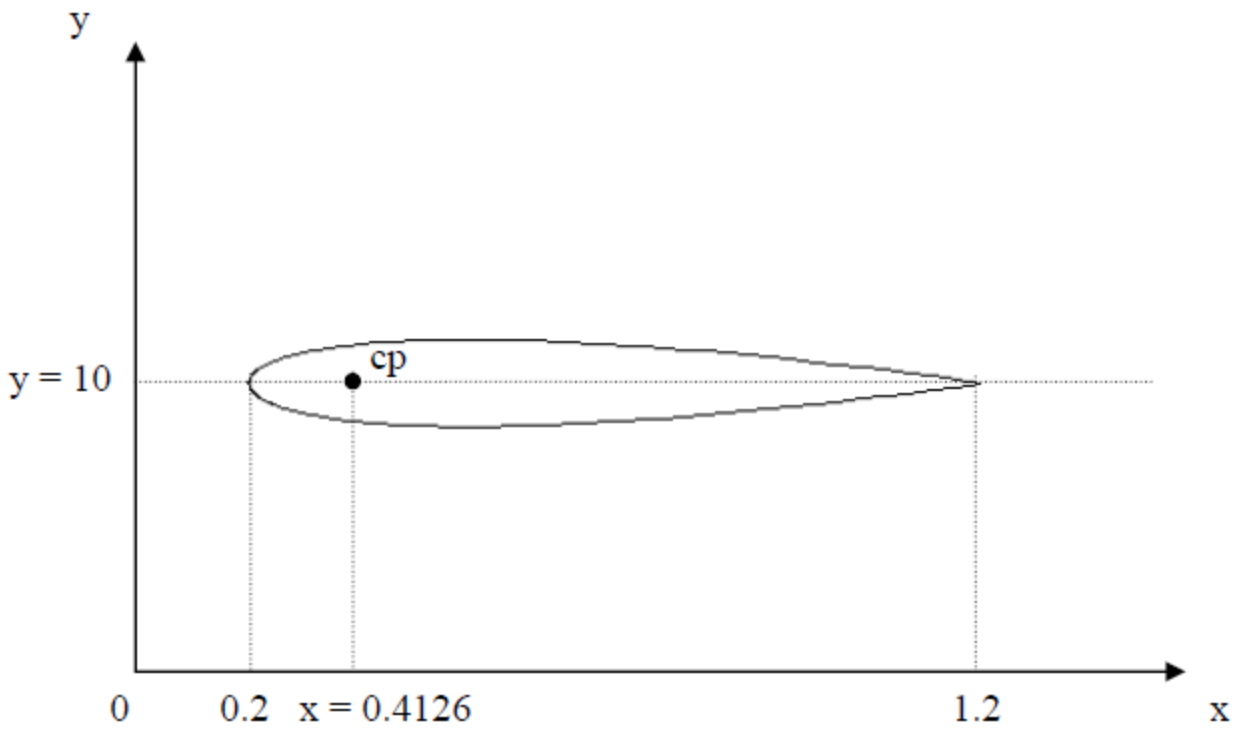
Important

Note that the reported force and moment coefficients are a function of the values entered in the **Reference Values** task page (as described in Computing Forces, Moments, and the Center of Pressure in the Theory Guide). Therefore, appropriate values must be entered in the **Reference Values** task page to get meaningful results.

32.5.1.1. Example

To demonstrate how you would generate and interpret the center of pressure report, consider an airfoil of chord length 1 m (shown in Figure 32.23: An Airfoil with its Computed Center of Pressure (p. 1918)).

Figure 32.23: An Airfoil with its Computed Center of Pressure

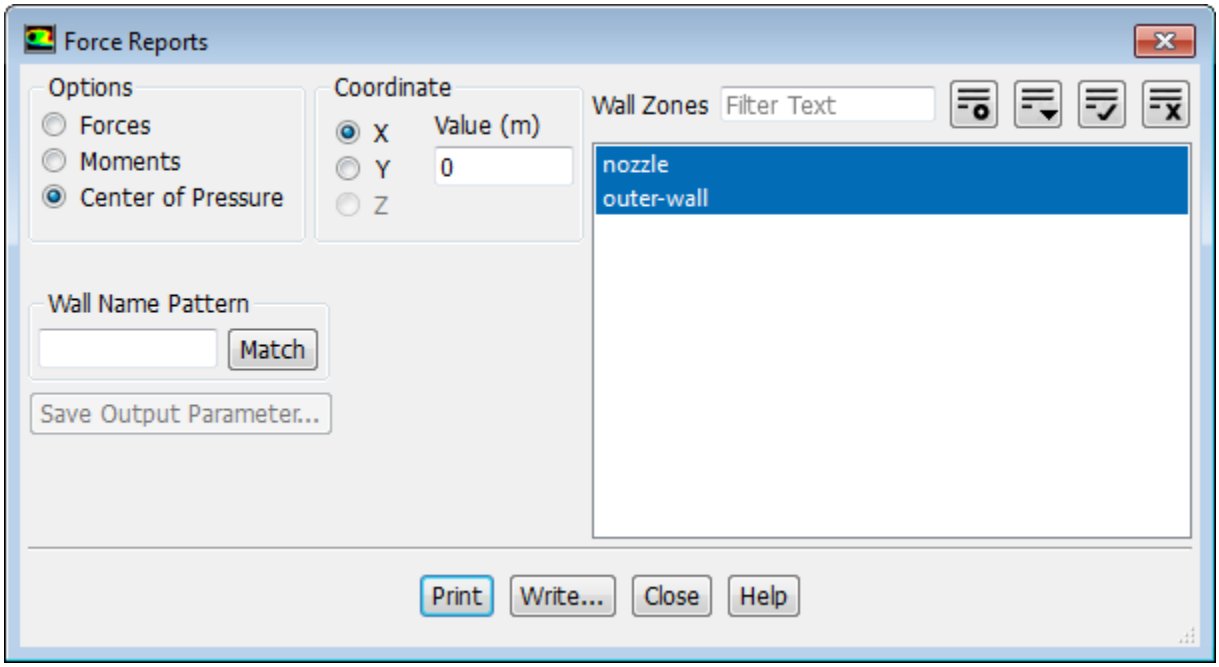


Open the **Force Reports** dialog box and perform the steps that follow.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Results → Reports → Forces Edit...

Figure 32.24: The Force Reports Dialog Box for a Center of Pressure Report



1. Select **Center of Pressure** from the **Options** list.
2. Define the line on which the center of pressure will be calculated. In this case, the **Y** coordinate for the line has a fixed **Value** of `10`.
3. Select the **Wall Zones** that are relevant for the computation.
4. Click **Print** to have the coordinates of the center of pressure displayed in the console window.

The report generated will be in the following form:

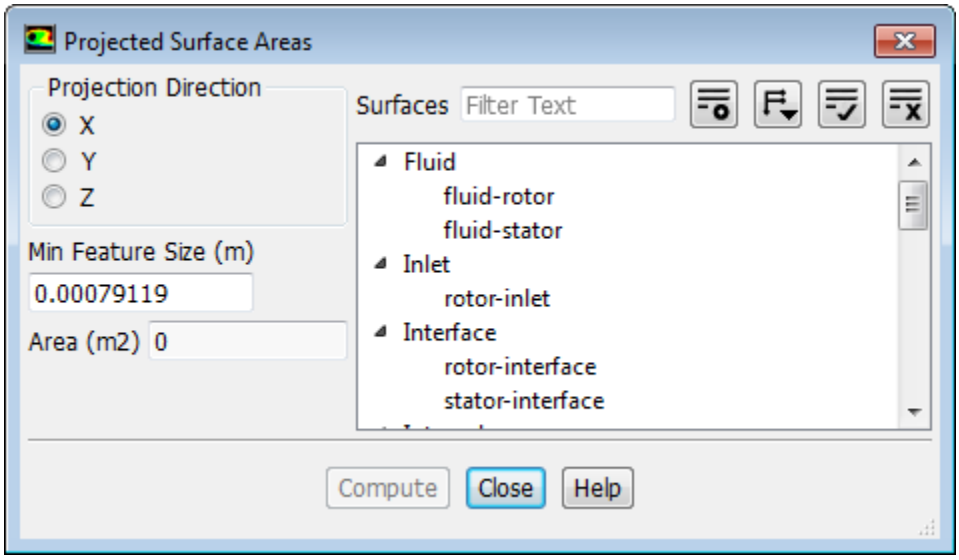
```
Pressure Center Coordinates (in m):
X = 0.41267981
Y = 10
```

32.6. Projected Surface Area Calculations

You can use the Projected Surface Areas Dialog Box (p. 2615) (Figure 32.25: The Projected Surface Areas Dialog Box (p. 1920)) to compute an estimated area of the projection of selected surfaces along the x, y, or z axis (that is, onto the yz, xz, or xy plane).

Results → Reports → Projected Areas Edit...

Figure 32.25: The Projected Surface Areas Dialog Box



The steps for calculating the projected area are as follows:

1. Select the **Projection Direction** (**X**, **Y**, or **Z**).
2. Choose the surface(s) for which the projected area is to be calculated in the **Surfaces** list.
3. Set the **Min Feature Size** to the length of the smallest feature in the geometry that you want to resolve in the area calculation. (You can just use the default value to start with, if you are not sure of the size of the smallest geometrical feature.)
4. Click **Compute**. The area will be displayed in the **Area** box and in the console window.
5. To improve the accuracy of the area calculation, reduce the **Min Feature Size** by half and recompute the area. Repeat this step until the computed **Area** stops changing (or you reach memory capacity).

This feature is available only for 3D domains.

32.7. Surface Integration

This section describes how to compute surface integrals. For mathematical definitions of the various integral types, refer to Computing Surface Integrals in the Theory Guide .

For additional information, see the following section:
32.7.1. Generating a Surface Integral Report

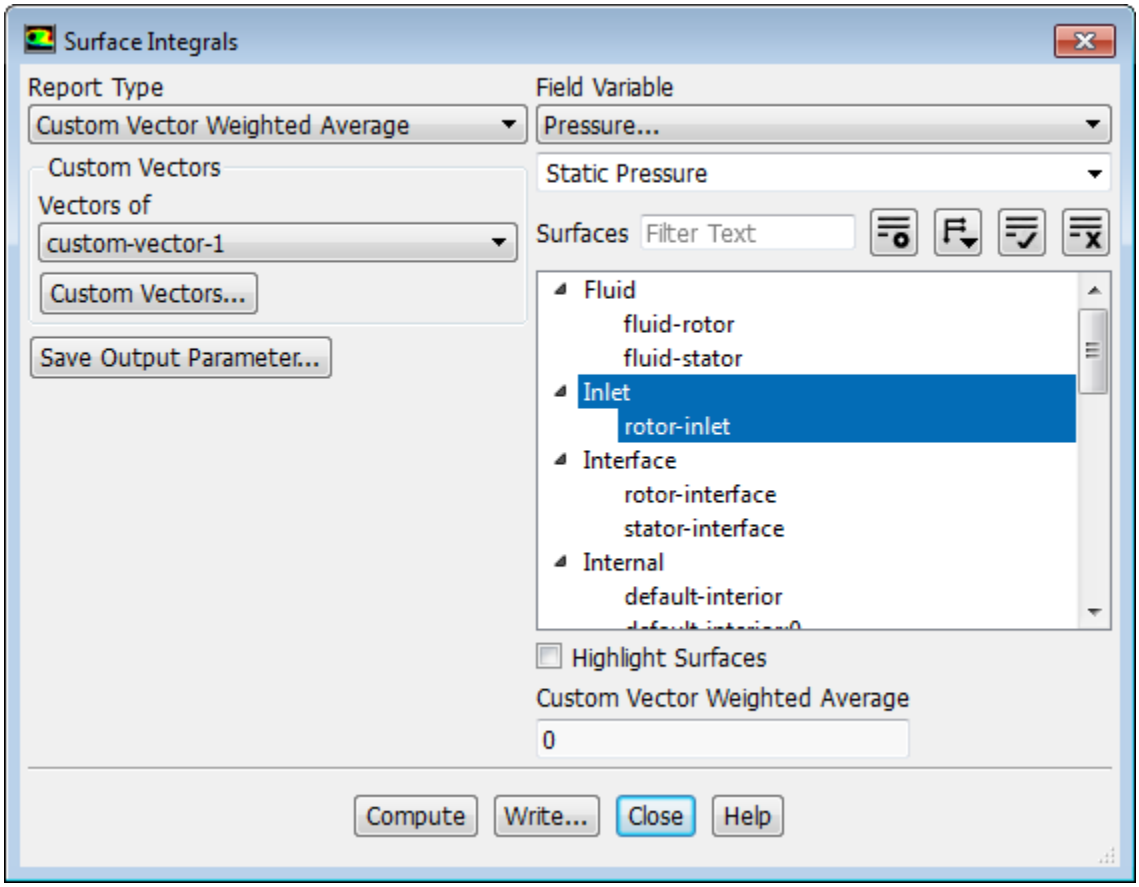
32.7.1. Generating a Surface Integral Report

To obtain a report for selected surfaces of the area, custom vector-based flux, custom vector flux, custom vector-weighted average, mass flow rate, or volume flow rate, or the integral, flow rate, standard deviation, sum, facet maximum, facet minimum, uniformity index (weighted by mass or area), vertex maximum, vertex minimum, or mass-, area-, facet-, or vertex-averaged quantity of a specified field variable, use the Surface Integrals Dialog Box (p. 2616) (Figure 32.26: The Surface Integrals Dialog Box (p. 1921)).

Results → Reports → Surface Integrals Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 32.26: The Surface Integrals Dialog Box



The steps for generating the report are as follows:

1. Specify which type of report you are interested in by selecting **Area**, **Area-Weighted Average**, **Custom Vector Based Flux**, **Custom Vector Flux**, **Custom Vector Weighted Average**, **Facet Average**, **Facet Minimum**, **Facet Maximum**, **Flow Rate**, **Integral**, **Mass Flow Rate**, **Mass-Weighted Average**, **Standard Deviation**, **Sum**, **Uniformity Index - Mass Weighted**, **Uniformity Index - Area Weighted**, **Vertex Average**, **Vertex Minimum**, **Vertex Maximum**, or **Volume Flow Rate** in the **Report Type** drop-down list.

2. If you selected **Custom Vector Based Flux**, **Custom Vector Flux**, or **Custom Vector Weighted Average** from the **Report Type** drop-down list, you must define vectors in the **Custom Vectors** group box.

3. If you are performing a multiphase simulation, you may need to select the phase of interest from the **Phase** drop-down list depending on the selected **Report Type**.

4. If you are generating a report of area, mass flow rate, or volume flow rate, skip to the next step. Otherwise, use the **Field Variable** drop-down lists to select the field variable to be used in the surface integrations. First, select the desired category in the upper drop-down list. You can then select a related quantity from the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

5. In the **Surfaces** list, choose the surface(s) on which to perform the surface integration.

6. To create an output parameter for the reported value, click **Save Output Parameter...**. The Save Output Parameter Dialog Box (p. 2631) (Figure 32.19: The Save Output Parameter Dialog Box (p. 1912)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of the same type. ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, parameter-1, parameter-2, and so on).

After the output parameter is created, it is listed in the Parameters Dialog Box (p. 2627). You can create any number of output parameters of this report type.

Note

If you create an output parameter from a surface integral report and save the case and data (write), an equivalent report definition will be created when you read in the case file.

---

7. Click the **Compute** button. The computed results are printed in the numeric result field and also in the ANSYS Fluent console.

   The **Net** *value reported in the ANSYS Fluent console corresponds to the specified calculation performed over the list of selected surfaces.*

8. To save the computed results to a file, click the **Write...** button and specify the filename in the resulting **Select File** dialog box.

Note the following:

- Mass averaging "weights" toward regions of higher velocity (that is, regions where more mass crosses the surface).
- Flow rates reported using the Surface Integrals Dialog Box (p. 2616) are not as accurate as those reported with the Flux Reports Dialog Box (p. 2613) (described in Fluxes Through Boundaries (p. 1911)).
- The facet and vertex average options are recommended for zero-area surfaces.
- The uniformity index represents how a specified field variable varies over a surface, where a value of 1 indicates the highest uniformity. The uniformity index can be weighted by area or mass: the area-weighted uniformity index captures the variation of the quantity (for example, the species concentration), whereas the mass-weighted uniformity index captures the variation of the flux (for example, the species flux). See Computing Surface Integrals in the Theory Guide for the equations used to calculate the uniformity index.

32.8. Volume Integration

This section describes how to compute volume integrals. For mathematical definitions of the various integral types, refer to Computing Volume Integrals in the Theory Guide .

For additional information, see the following section:
32.8.1. Generating a Volume Integral Report

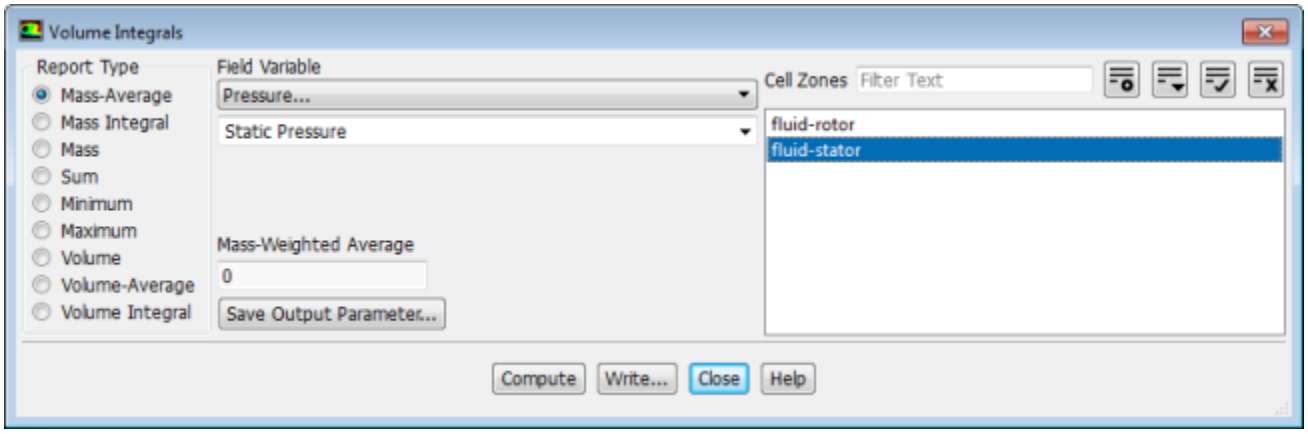
32.8.1. Generating a Volume Integral Report

To obtain a report (of quantities such as the volume, sum, minimum, maximum, volume integral, volume-weighted average, mass-weighted integral, or mass-weighted average) for selected cell zones for a specified field variable, use the Volume Integrals Dialog Box (p. 2620) (Figure 32.27: The Volume Integrals Dialog Box (p. 1923)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Results → Reports → Volume Integrals Edit...

Figure 32.27: The Volume Integrals Dialog Box



The steps for generating the report are as follows:

1. Specify which type of report you are interested in by selecting **Volume**, **Sum**, **Sum*2Pi** (only available for 2D Axisymmetric cases), **Maximum**, **Minimum**, **Volume Integral**, **Volume-Average**, **Mass**, **Mass Integral**, or **Mass-Average** under **Report Type**.

2. If you are generating a report of **Volume** or **Mass**, skip to the next step. Otherwise, use the **Field Variable** drop-down lists to select the field variable to be used in the integral, sum, or averaged volume integrations. First, select the desired category in the upper drop-down list. You can then select a related quantity from the lower list. (See Field Function Definitions (p. 1931) for an explanation of the variables in the list.)

3. If you are performing a multiphase simulation, select the phase of interest (or **mixture**) from the **Phase** drop-down list.

4. In the **Cell Zones** list, choose the zones on which to compute the volume, sum, max, min, volume integral, volume-weighted average, mass integral, or mass-averaged quantity.

5. To create an output parameter for the reported value, click **Save Output Parameter...**. The Save Output Parameter Dialog Box (p. 2631) (Figure 32.19: The Save Output Parameter Dialog Box (p. 1912)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, parameter-1, parameter-2, and so on).

   After the output parameter is created, it is listed in the Parameters Dialog Box (p. 2627). You can create any number of output parameters of this report type.

   Note

   If you create an output parameter from a volume integral report and save the case and data (write), an equivalent report definition will be created when you read in the case file.

6. Click the **Compute** button. The computed results are printed in the numeric result field and also in the ANSYS Fluent console.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Net** *value reported in the ANSYS Fluent console corresponds to the specified calculation performed over the list of selected cell zones.*

7. To save the computed results to a file, click the **Write...** button and specify the filename in the resulting **Select File** dialog box.

32.9. Histogram Reports

In ANSYS Fluent, you can print geometric and solution data in the console (text) window in histogram format or plot a histogram in the graphics window. Graphical display of histograms and the procedures for defining a histogram are discussed in Histograms (p. 1851).

The number of cells, the range of the selected variable or function, and the percentage of the total number of cells in the interval will be reported, as in the example below:

```
0 cells below 1.195482 (0 %)
2 cells between 1.195482 and 1.196048 (4.1666667 %)
1 cells between 1.196048 and 1.196614 (2.0833333 %)
0 cells between 1.196614 and 1.19718 (0 %)
0 cells between 1.19718 and 1.197746 (0 %)
2 cells between 1.197746 and 1.198312 (4.1666667 %)
1 cells between 1.198312 and 1.198878 (2.0833333 %)
6 cells between 1.198878 and 1.199444 (12.5 %)
9 cells between 1.199444 and 1.20001 (18.75 %)
25 cells between 1.20001 and 1.200576 (52.083333 %)
2 cells between 1.200576 and 1.201142 (4.1666667
0 cells above 1.201142 (0 %)
```

To generate such a printed histogram, use the Histogram Dialog Box (p. 2598).

Results → Plots → Histogram Edit...

Follow the instructions in Histograms (p. 1851) for generating histogram plots, but click **Print** instead of **Plot** to create the report.

32.10. Discrete Phase

ANSYS Fluent allows you to write particle states (position, velocity, diameter, temperature, and mass flow rate) to files at various boundaries and planes (lines in 2D) using the Sample Trajectories Dialog Box (p. 2622) (Figure 23.47: The Sample Trajectories Dialog Box (p. 1355)). Information about discrete phase reporting is discussed in detail in Sampling of Trajectories (p. 1355), Histogram Reporting of Samples (p. 1356), and Summary Reporting of Current Particles (p. 1358).

32.11. S2S Information

ANSYS Fluent allows you to view the values of the view factor and radiation emitted from one zone to another. You will use the S2S Information Dialog Box (p. 2792) (Figure 12.31: The S2S Information Dialog Box (p. 886)) to generate a report of these values. For details on reporting S2S information, refer to Reporting Radiation in the S2S Model (p. 885).

32.12. Reference Values

You can control the reference values that are used in the computation of derived physical quantities and non-dimensional coefficients. These reference values are used only for postprocessing.

Some examples of the use of reference values include the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Force coefficients use the reference area, density, and velocity. In addition, the pressure force calculation uses the reference pressure.
- Moment coefficients use the reference length, area, density and velocity. In addition, the pressure force calculation uses the reference pressure.
- Reynolds number uses the reference length, density, and viscosity.
- Pressure and total pressure coefficients use the reference pressure, density, and velocity.
- Entropy uses the reference density, pressure, and temperature.
- Skin friction coefficient uses the reference density and velocity.
- Heat transfer coefficient uses the reference temperature.
- Turbomachinery efficiency calculations use the ratio of specific heats.

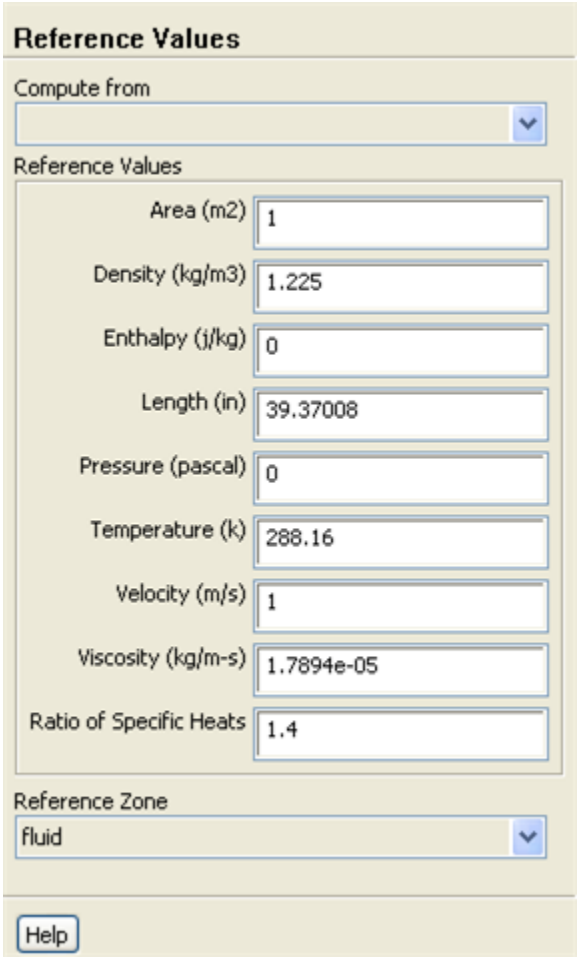
For additional information, see the following sections:
32.12.1. Setting Reference Values
32.12.2. Setting the Reference Zone

32.12.1. Setting Reference Values

To set the reference quantities used for computing normalized flow-field variables, use the Reference Values Task Page (p. 2502) (Figure 32.28: The Reference Values Task Page (p. 1926)).

Setup → Reference Values

Figure 32.28: The Reference Values Task Page



You can specify the reference values manually or compute them based on values of physical quantities at a selected boundary zone. The reference values to be set are **Area**, **Density**, **Enthalpy**, **Length**, **Pressure**, **Temperature**, **Velocity**, dynamic **Viscosity**, and **Ratio Of Specific Heats**.

For 2D problems, an additional quantity, **Depth**, can also be defined. This quantity will be used for reporting fluxes and forces, as well as relevant variables computed using the Surface Integrals Dialog Box (p. 2616) and the Volume Integrals Dialog Box (p. 2620) (for example, **Area**, **Flow Rate**, **Mass Flow Rate**, **Volume**, and so on). You should verify that the value and units of **Depth** corresponds to the depth dimension of your application prior to reporting any of the variables above.

Important

The units for **Depth** are set independently from the units for **Length** in the Set Units Dialog Box (p. 2166).

If you want to compute reference values from the conditions set on a particular boundary zone, select the zone in the **Compute From** drop-down list. Note, however, that depending on the boundary condition used, only some of the reference values may be set. For example, the reference length and area will not be set by computing the reference values from a boundary condition; you will need to set these manually.

To set the values manually, simply enter the value for each under the **Reference Values** heading.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

32.12.2. Setting the Reference Zone

If you are solving a flow involving multiple reference frames or sliding meshes, you can plot velocities and other related quantities relative to the motion of a specified "reference zone". Choose the desired zone in the **Reference Zone** drop-down list. Changing the reference zone allows you to plot velocities (and total pressure, temperature, and so on) relative to the motion of different zones. See Modeling Flows with Moving Reference Frames (p. 603) for details about postprocessing of relative quantities.

32.13. Summary Reports of Case Settings

You may sometimes find it useful to get a report of the current settings in your case. In ANSYS Fluent, you can list the settings for physical models, boundary conditions, material properties, and solver controls. This report allows you to get an overview of your current problem definition quickly, instead of having to check the settings in each dialog box.

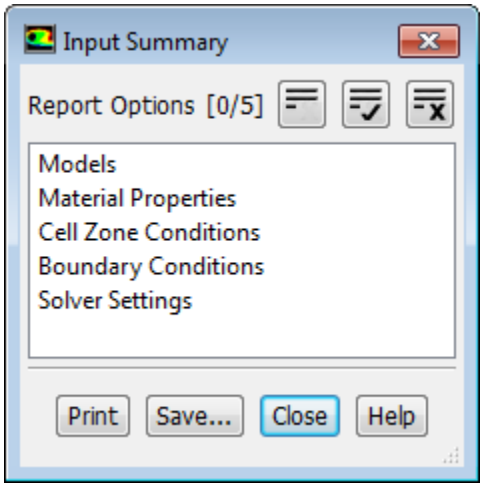
For additional information, see the following section:
32.13.1. Generating a Summary Report

32.13.1. Generating a Summary Report

To generate a summary report you will use the Input Summary Dialog Box (p. 2717) (Figure 32.29: The Input Summary Dialog Box (p. 1927)).

Solving → **Run Calculation** → **Input Summary...**

Figure 32.29: The Input Summary Dialog Box



The steps are as follows:

1. Select the information you would like to see in the report (**Models**, **Boundary Conditions**, **Solver Controls**, and/or **Material Properties**) in the **Report Options** list.

2. To print the information to the ANSYS Fluent console window, click the **Print** button. To save the information to a text file, click the **Save...** button and specify the filename in the resulting **Select File** dialog box.

32.14. System Resource Usage

You can print several reports of memory and processor usage from the **Parallel** ribbon tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

32.14.1. Processor Information
32.14.2. Memory Information
32.14.3. Process and Model Timers

32.14.1. Processor Information

You can print out a table summarizing the processor usage on each machine that has compute processes spawned for the current session by clicking **CPU Info** and selecting **CPU Info** in the **Parallel** ribbon tab (**System** group box). For example, if processes have been spawned on three machines, a table similar to the following is displayed:

```
-------------------------------------------------------------------------------
                   | CPU                                  | System Mem (GB)
Hostname           | Sock x Core  Clock (MHz)  Load       | Total        Available
-------------------------------------------------------------------------------
host23             | 8 x 8, HT    2399.85      0.07       | 129.039      89.565
host24             | 8 x 8, HT    2399.95      1.08       | 129.039      32.516
host25             | 8 x 8, HT    2400.4       3.14       | 129.039      62.531
-------------------------------------------------------------------------------
Total              | 192          -            -          | 387.117      184.612
-------------------------------------------------------------------------------
```

Under CPU:

Sock x Core
displays the number of processor sockets, number of cores per socket, and whether hyper-threading is used.

Clock (MHz)
is the processor speed.

Load
is the work load on the machine.

Under `System Mem (GB)`:

Total
is the total system memory on the machine.

Available
is the available system memory on the machine.

If you are running in parallel, you can print out information about the GPUs available on the machine by clicking **CPU Info** and selecting **GPU Info** in the **Parallel** ribbon tab (**System** group box). If your machine has one or more suitable GPUs present, you can use these to accelerate parallel processing computations as described in Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver (p. 2056).

```
CUDA visible GPUs on host01
  CUDA runtime version 5000
  Driver version 6000
  Number of GPUs 1
    0. Quadro K2100M
       3 SMs
       0.6665 GHz
       2.14748 GBytes
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

32.14.2. Memory Information

You can print out tables summarizing memory usage by node and by host by clicking **CPU Info** and selecting **Memory Usage** in the **Parallel** ribbon tab (**System** group box).

```

Under `Virtual Mem Usage (GB)`:

Current
is the virtual memory usage at the time the report is generated.

Peak
is the peak virtual memory usage.

(Linux only) Under `Resident Mem Usage (GB)`:

Current
is the resident memory usage at the time the report is generated.

Peak
is the peak resident memory usage.

Page Faults
is the number of page faults that have occurred.

You can use these commands to plan ANSYS Fluent jobs and machines accordingly. They may also be useful to diagnose performance problems.

32.14.3. Process and Model Timers

You can print out detailed information about the CPU timings for the current session as well as solver timings by clicking **CPU Info** and selecting **Time Usage** in the **Parallel** ribbon tab (**System** group box). The solver timings presented are described in Checking Parallel Performance (p. 2060).

Chapter 33: Field Function Definitions

You must select flow variables for a number of tasks in ANSYS Fluent. The values are computed and placed in temporary memory that is allocated for storing the results for each cell. For example, the **Compute** command associated with a dialog box that contains the field variable drop-down list calculates the adjvalues of the selected function and places them into temporary storage.

Node, Cell, and Facet Values (p. 1931) and Velocity Reporting Options (p. 1933) provide some general information related to the field variables. In Field Variables Listed by Category (p. 1934), the variables are listed by category in Table 33.1: **Pressure** and **Density** Categories (p. 1937) – Table 33.17: **Acoustics** Category (p. 1956). These tables will also indicate when each variable will be available. Alphabetical Listing of Field Variables and Their Definitions (p. 1957) contains an alphabetical listing of the variables along with their definitions. All variables appear as they would in the variable selection drop-down lists that are contained in many of the ANSYS Fluent dialog boxes. Custom Field Functions (p. 2003) explains how you can calculate your own field function.

33.1. Node, Cell, and Facet Values
33.2. Velocity Reporting Options
33.3. Field Variables Listed by Category
33.4. Alphabetical Listing of Field Variables and Their Definitions
33.5. Custom Field Functions

33.1. Node, Cell, and Facet Values

For the following discussion, "surface" refers to a collection of facets, lines or points that are created and manipulated in the **Setting Up Domain** ribbon tab. In most cases, these surfaces are created by computing intersections of constant isovalues with the domain cells or with existing surfaces.

For additional information, see the following sections:

33.1.1. Cell Values
33.1.2. Node Values
33.1.3. Facet Values

33.1.1. Cell Values

ANSYS Fluent stores most variables in cells. For postprocessing, the entire region contained within the cell has this value. A surface cell value is the value of the cell that has been intersected by a surface facet or line, or that contains a surface point. Since surface facets and lines are created from the intersection of isovalues and the existing mesh cells, this is a unique definition. Typically, the cell value on a boundary is the value in the cell adjacent to the boundary. For face-only functions like **Wall Shear Stress**, the cell value is the area-weighted average from the face values that define that cell as `c0`. This value is used for the cell values of postprocessing surfaces. But for boundary faces, the cell value actually displays/uses the exact face value.

33.1.2. Node Values

Node values are explicitly defined or obtained by weighted averaging of the cell data. Various boundary conditions impose values of field variables at the domain boundaries, so mesh node values on these

boundary zones are obtained by simple averaging of the adjacent boundary face data. In addition, for several variables (for example, node coordinates) explicit node values are available at all nodes.

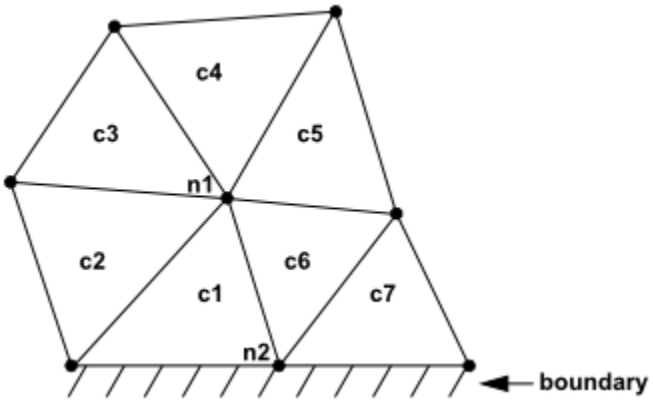
Computation of node values is performed in two steps:

1. Values at all nodes are initialized to the weighted average of the surrounding cell values. The weights are the inverses of the cell volumes that neighbor the nodes.

2. At boundaries, these node values are overwritten with the simple average of the boundary face values. Variables for which explicit node values are available at boundaries are indicated by *bnv* in Table 33.1: **Pressure** and **Density** Categories (p. 1937) – Table 33.17: **Acoustics** Category (p. 1956).

For example, in Figure 33.1: Computing Node Values (p. 1932), the value at node $n1$ will be computed from the weighted average of the values in the surrounding cells ($c1$—$c6$). The value at node $n2$ will be computed from the simple average of the boundary faces ($bf1$ and $bf2$) if there are explicit boundary values available for the variable in question.

Figure 33.1: Computing Node Values



Important

Note that explicit boundary node values are not available for custom field functions.

33.1.2.1. Vertex Values for Points That are Not Mesh Nodes

The values of the nodes on surfaces are linearly interpolated from the mesh node data. For zone surfaces, the nodes on the surface and the zone correspond; therefore, the values are identical. For surfaces that are not zone surfaces (for example, isosurfaces, plane surfaces, and so on), the node values are interpolated from mesh nodes on the cell faces intersected by the postprocessing surface. For point surfaces, the value is interpolated from all the mesh nodes of the cell containing the point.

33.1.3. Facet Values

Facets can be created on preprocessing surfaces and postprocessing surfaces.

33.1.3.1. Facet Values on Zone Surfaces

The interior facets on a zone surface are associated with two cells (`c0` and `c1`). The values of a specified variable on such facets are computed as the arithmetic average of the two cell values of the selected variable.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The boundary facet values of a primary field variables on a zone surface are taken from the specified boundary conditions. The boundary values of dependent variables are computed from the adjacent cell values (versus using the value of the primary variable specified at the boundary). For exact values of dependent variables at the boundaries, define a custom field function specifying the boundary conditions as the primary variables. For more information on custom field functions, see Custom Field Functions (p. 2003).

33.1.3.2. Facet Values on Postprocessing Surfaces

Each facet on a postprocessing surface is associated with a cell. The values of a specified variable on facets are the same as the cell values of the selected variable in the associated cells (this includes iso surfaces, planes, lines, points, rakes, quadric, and so on).

33.2. Velocity Reporting Options

The following methods are available for reporting velocities:

- Cartesian velocities:

  These velocities are based on the Cartesian coordinate system used by the geometry. To report Cartesian velocities, select **X Velocity**, **Y Velocity**, or **Z Velocity**. This is the most common type of velocity reported.

- Cylindrical velocities:

  These velocities are the axial, radial, and tangential components based on the following coordinate systems:

  – For axisymmetric problems, in which the rotation axis must be the x axis, the x direction is the axial direction and the y direction is the radial direction. (If you model axisymmetric swirl, the swirl direction is the tangential direction.)

  – For 2D problems involving a single cell zone, the z direction is the axial direction, and its origin is specified in the Fluid Dialog Box (p. 2369).

  – For 3D problems involving a single cell zone, the coordinate system is defined by the rotation axis and origin specified in the Fluid Dialog Box (p. 2369).

  – For problems involving multiple zones (for example, multiple reference frames or sliding meshes), the coordinate system is defined by the rotation axis specified in the Fluid Dialog Box (p. 2369) (or Solid Dialog Box (p. 2379)) for the "reference zone". The reference zone is chosen in the Reference Values Task Page (p. 2502), as described in Reference Values (p. 1924). Recall that for 2D problems, you will specify only the axis origin; the z direction is always the axial direction.

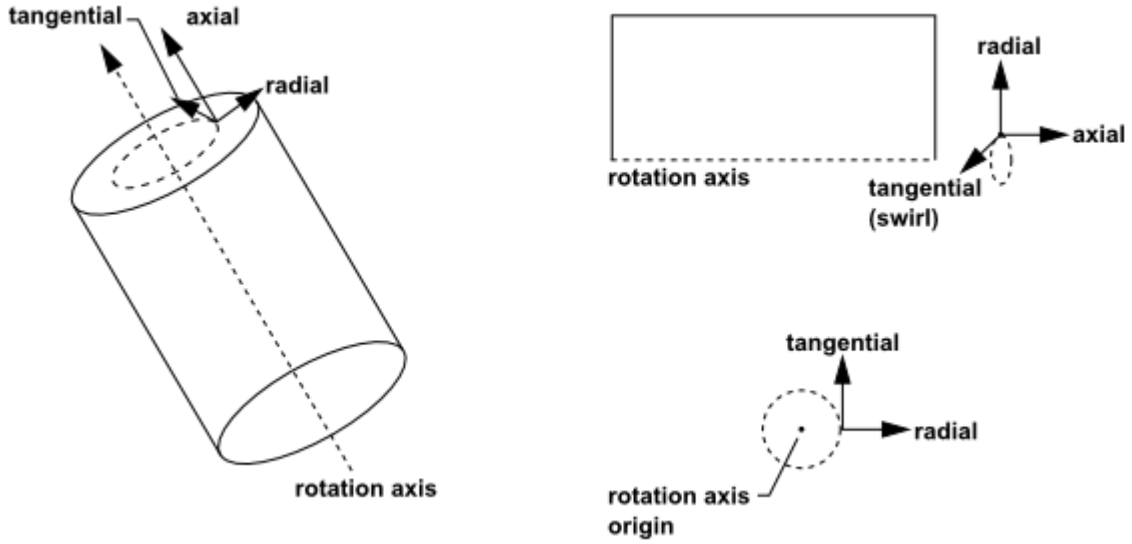
  For all of the above definitions of the cylindrical coordinate system, positive radial velocities point radially out from the rotation axis, positive axial velocities are in the direction of the rotation axis vector, and positive tangential velocities are based on the right-hand rule using the positive rotation axis.

  To report cylindrical velocities, select **Axial Velocity**, **Radial Velocity**, and so on. Figure 33.2: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 1934) illustrates the cylindrical velocities available for different types of domains. For 3D problems, you can report axial, radial, and tangential velocities. For 2D problems, radial and tangential velocities are available. For axisymmetric problems,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you can report axial and radial velocities, and, if you are modeling axisymmetric swirl, you can also report the swirl velocity (which is equivalent to the tangential velocity).

Figure 33.2: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains



- Relative velocities: These velocities are based on the coordinate system and motion of a moving reference frame. They are useful when you are modeling your flow using a moving reference frame, a mixing plane, multiple reference frames, or sliding meshes. (See Modeling Flows with Moving Reference Frames (p. 603) for information about modeling flow in moving zones.) To report relative velocities, select **Relative X Velocity**, **Relative Y Velocity**, **Relative Radial Velocity**, and so on. (Note that you can report relative velocities for both Cartesian and cylindrical components.)

  If you are using a single moving reference frame, the relative velocity values will be reported with respect to the moving frame. If you are using multiple reference frames, mixing planes, or sliding meshes, you will need to specify the frame to which you want the velocities to be relative by choosing the appropriate cell zone as the **Reference Zone** in the Reference Values Task Page (p. 2502) (see Reference Values (p. 1924)). The axis of rotation for each cell zone is defined in the associated Fluid Dialog Box (p. 2369) or Solid Dialog Box (p. 2379). (See Specifying the Rotation Axis (p. 255) or Specifying the Rotation Axis (p. 260) for details.)

  Note that if your problem does not involve any moving zones, relative and absolute velocities will be equivalent.

Note that relative velocities can also be used to compute stagnation quantities (total pressure and total temperature), and that the cylindrical coordinate systems described in the second item above are used for defining the **Axial Coordinate** and **Radial Coordinate** as well.

33.3. Field Variables Listed by Category

In Table 33.1: **Pressure** and **Density** Categories (p. 1937) – Table 33.17: **Acoustics** Category (p. 1956), the following restrictions apply to marked variables:

2d	available only for 2D flows
2da	available only for 2D axisymmetric flows (with or without swirl)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2dasw	available only for 2D axisymmetric swirl flows
3d	available only for 3D flows
adj	available only with data is available from the adjoint solver
ark	available only with the Aungier-Redlich-Kwong real gas model
asfft	available only when created using the Acoustic Sources FFT Dialog Box (p. 2549) or related text commands
bns	available only for broadband noise source models
bnv	node values available at boundaries
cmp	available only for compressible flow
cpl	available only in the density-based solvers
cv	available only for cell values (**Node Values** option turned off)
ddpm	available only when the DDPM model is used
des	available when the turbulence model includes the DES turbulence model
dil	not available with full multicomponent diffusion
do	available only when the discrete ordinates radiation model is used
dpm	available only for coupled discrete phase calculations
dpmean	available only when Mean Values are enabled in the DPM dialog box
dprms	available only when RMS Values are enabled in the DPM dialog box
dtrm	available only when the discrete transfer radiation model is used
fwh	available only with the Ffowcs Williams and Hawkings acoustics model
e	available only for energy calculations
echem	available only with the Electrochemical Reactions model
edc	available only with the EDC model for turbulence-chemistry interaction
emm	available also when the Eulerian multiphase model is used
ewf	available only with the Eulerian Wall Film model
ewt	available only with the enhanced wall treatment
fv	available for face values

gran	available only if a granular phase is present
h2o	available only when the mixture contains water
id	available only when the ideal gas law is enabled for density
ke	available when one of the k-ε turbulence models is used
kklo	available when the k-kl-ω model is used
kw	available when one of the k-ω turbulence models is used
les	available when the LES turbulence model is used
lwf	available only when the Lagrangian wall film model is used
melt	available only when the melting and solidification model is used
mix	available only when the multiphase mixture model is used
mp	available only for multiphase models
netm	available only for porous cell zones with the non-equilibrium thermal model enabled
nox	available only for NOx calculations
np	not available in parallel solvers
nv	uses explicit node value function
os	available only when overset meshing is used
p	available only in parallel solvers
p1	available only when the P-1 radiation model is used
pdf	available only for non-premixed combustion calculations
pmx	available only for premixed combustion calculations
pot	available only when the potential equation is solved
ppmx	available only for partially premixed combustion calculations
r	available only when the Rosseland radiation model is used
rad	available only for radiation heat transfer calculations
rc	available only for finite-rate reactions
rg	available only for the real gas models
rsm	available when the Reynolds stress turbulence model is used

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

s2s	available only when the surface-to-surface radiation model is used
sa	available when the Spalart-Allmaras turbulence model is used
sas	available when the turbulence model includes Scale-Adaptive Simulation (SAS)
sbes	available when the turbulence model includes the Stress-Blended Eddy Simulation (SBES) turbulence model
sdes	available when the turbulence model includes the Shielded Detached Eddy Simulation (SDES) turbulence model
seg	available only in the pressure-based solver
sp	available only for species calculations
sr	available only for surface reactions
sol	available only when the solar model is used
soot	available only for soot calculations
sst	available when the Transition SST model is used
stat	available only with data sampling for transient statistics
stcm	available only for stiff chemistry calculations
t	available only for turbulent flows
th	available only when thin walls are present
turbo	available only when a turbomachinery topology has been defined
udm	available only when a user-defined memory is used
uds	available only when a user-defined scalar is used
v	available only for viscous flows

33.4. Alphabetical Listing of Field Variables and Their Definitions

Below, the variables listed in Table 33.1: **Pressure** and **Density** Categories (p. 1937) – Table 33.17: **Acoustics** Category (p. 1956) are defined. For some variables (such as residuals) a general definition is given under the category name, and variables in the category are not listed individually. When appropriate, the unit quantity is included, as it appears in the **Quantities** list in the Set Units Dialog Box (p. 2166).

Abs. Angular Coordinate

(in the **Mesh...** category) is the absolute value of the **Angular Coordinate** defined above.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Abs (C-H) Spanwise Coordinate
(in the **Mesh...** category) is the dimensional coordinate in the spanwise direction, from casing to hub. Its unit quantity is **length**.

Abs (H-C) Spanwise Coordinate
(in the **Mesh...** category) is the dimensional coordinate in the spanwise direction, from hub to casing. Its unit quantity is **length**.

Abs Meridional Coordinate
(in the **Mesh...** category) is the dimensional coordinate that follows the flow path from inlet to outlet. Its unit quantity is **length**.

Abs Pitchwise Coordinate
(in the **Mesh...** category) is the dimensional coordinate in the circumferential (pitchwise) direction. Its unit quantity is **angle**.

Absolute Pressure
(in the **Pressure...** category) is equal to the operating pressure plus the gauge pressure. See Operating Pressure (p. 530) for details. Its unit quantity is **pressure**.

Absorbed Radiation Flux (Band-n)
(in the **Wall Fluxes...** category) is the amount of radiative heat flux absorbed by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Absorbed Visible Solar Flux, Absorbed IR Solar Flux
(in the **Wall Fluxes...** category) is the amount of solar heat flux absorbed by a semi-transparent wall or porous jump boundary for a visible or infrared (IR) radiation.

Absorption Coefficient
(in the **Radiation...** category) is the property of a medium that describes the amount of absorption of thermal radiation per unit path length within the medium. It can be interpreted as the inverse of the mean free path that a photon will travel before being absorbed (if the absorption coefficient does not vary along the path). The unit quantity for **Absorption Coefficient** is **length-inverse**.

Accum Parcels in Cell
(in the **Unsteady DPM Statistics...** category) is the cumulative count of parcels passing through a cell since the last reset of the unsteady statistics

Accum Particles in Cell
(in the **Unsteady DPM Statistics...** category) is the cumulative count of particles passing through a cell since the last reset of the unsteady statistics

Acentric Factor
(in the **Properties...** category) is the mixture acentric factor. This property is available when a composition dependent option is selected for acentric factor in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Acoustic Power
(in the **Acoustics...** category) is the acoustic power per unit volume generated by isotropic turbulence (see Equation 15.11 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used. Its unit quantity is **power** per **volume**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Acoustic Power Level (dB)

(in the **Acoustics...** category) is the acoustic power per unit volume generated by isotropic turbulence and reported in dB (see Equation 15.14 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Active Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS Fluent, the partition ID can be used to determine the extent of the various groups of cells. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file. See Partitioning the Mesh Manually and Balancing the Load (p. 2033) for more information.

Adaption...

includes field variables that are commonly used for adapting the mesh. For information about solution adaption, see Adapting the Mesh (p. 1681).

Adaption Function

(in the **Adaption...** category) can be either the **Adaption Space Gradient** or the **Adaption Curvature**, depending on the settings in the Gradient Adaption Dialog Box (p. 2710). For instance, the **Adaption Curvature** is the undivided Laplacian of the values in temporary cell storage. To display contours of the Laplacian of pressure, for example, you first select **Static Pressure**, click the **Compute** (or **Display**) button, select **Adaption Function**, and finally click the **Display** button.

Adaption Iso-Value

(in the **Adaption...** category) is the desired field variable function.

Adaption Space Gradient

(in the **Adaption...** category) is the first derivative of the desired field variable.

$$|e_{i1}| = \left(A_{cell}\right)^{\frac{r}{2}} |\nabla f| \tag{33.1}$$

Depending on the settings in the Gradient Adaption Dialog Box (p. 2710), this equation will either be scaled or normalized. Recommended for problems with shock waves (that is, supersonic, inviscid flows). For more information, see Gradient Adaption Approach in the Theory Guide .

Adaption Curvature

(in the **Adaption...** category) is the second derivative of the desired field variable.

$$|e_{i2}| = \left(A_{cell}\right)^{\frac{r}{2}} |\nabla^2 f| \tag{33.2}$$

Depending on the settings in the Gradient Adaption Dialog Box (p. 2710), this equation will either be scaled or normalized. Recommended for smooth solutions (that is, viscous, incompressible flows). For more information, see Gradient Adaption Approach in the Theory Guide .

Adiabatic Flame Temperature

(in the **Premixed Combustion...** category) is the adiabatic temperature of burnt products in a laminar premixed flame (T_b in Equation 9.68 in the Theory Guide). Its unit quantity is **temperature**.

Adjoint Local Solution Marker

(in the **Sensitivities...** category), intended for expert users, can be plotted to identify those portions of the flow domain where the stabilized adjoint solution advancement scheme is applied. It is preferable to plot this with the **Node Values** de-selected in the **Contours** dialog box. In this case, the **Adjoint Local**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution Marker will take a value between 0 and 1. The **Mode Amplitude Cutoff** defined in the **Stabilized Scheme Settings** dialog box defines the lower bound for cells where the stabilized scheme is applied.

Angular Coordinate

(in the **Mesh...** category) is the angle between the radial vector and the position vector. The radial vector is obtained by transforming the default radial vector (y-axis) by the same rotation that was applied to the default axial vector (z-axis). This assumes that, after the transformation, the default axial vector (z-axis) becomes the reference axis. The angle is positive in the direction of cross-product between reference axis and radial vector.

Average Number of Particles in Soot Aggregate

(In the **Soot…** category) is an average number of primary particles in a soot aggregate (n_p in equation Equation 14.185 in the *Fluent Theory Guide*). This quantity is available only with the Method of Moments model.

Axial Coordinate

(in the **Mesh...** category) is the distance from the origin in the axial direction. The axis origin and (in 3D) direction is defined for each cell zone in the Fluid Dialog Box (p. 2369) or Solid Dialog Box (p. 2379). The axial direction for a 2D model is always the z direction, and the axial direction for a 2D axisymmetric model is always the x direction. The unit quantity for **Axial Coordinate** is **length**.

Axial Pull Velocity

(in the **Solidification/Melting...** category) is the axial-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Axial Velocity

(in the **Velocity...** category) is the component of velocity in the axial direction. (See Velocity Reporting Options (p. 1933) for details.) For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. Its unit quantity is **velocity**.

Axial-Wall Shear Stress

(in the **Wall Fluxes...** category) is the axial component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Beam Irradiation Flux (Band-b)

(in the **Wall Fluxes...** category) is specified as an incident heat flux (W / m^2) for each wavelength band.

Boundary Cell Distance

(in the **Adaption...** category) is an integer that indicates the approximate number of cells from a boundary zone.

Boundary Normal Distance

(in the **Adaption...** category) is the distance of the cell centroid from the closest boundary zone.

Boundary Volume Distance

(in the **Adaption...** category) is the cell volume distribution based on the **Boundary Volume**, **Growth Factor**, and normal distance from the selected **Boundary Zones** defined in the Boundary Adaption Dialog Box (p. 2673). See Boundary Adaption (p. 1685) for details.

Cell Children

(in the **Adaption...** category) is a binary identifier based on whether a cell is the product of a cell subdivision in the hanging-node adaption process (value = 1) or not (value = 0).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cell Acoustic Courant Number

(in the **Velocity...** category) is a ratio of the time step size to the acoustic wave propagation time based on the cell size.

Cell Convective Courant Number

(in the **Velocity...** category) is a ratio of the time step size to the convective wave propagation time based on the cell size.

Cell Element Type

(in the **Cell Info...** category) is the integer cell element type identification number. Each cell can have one of the following element types:

```
triangle     1
tetrahedron  2
quadrilateral 3
hexahedron   4
pyramid    5
wedge      6
polyhedra  7
```

Cell Equiangle Skew

(in the **Mesh...** category) is a nondimensional parameter calculated using the normalized angle deviation method, and is defined as

$$\max\left[\frac{q_{max}-q_e}{180-q_e}, \frac{q_e-q_{min}}{q_e}\right] \tag{33.3}$$

where

q_{max} = largest angle in the face or cell

q_{min} = smallest angle in the face or cell

q_e = angle for an equiangular face or cell (for example, 60 for a triangle and 90 for a square)

A value of 0 indicates a best case equiangular cell, and a value of 1 indicates a completely degenerate cell. Degenerate cells (slivers) are characterized by nodes that are nearly coplanar (collinear in 2D). **Cell Equiangle Skew** applies to all elements.

Cell Equivolume Skew

(in the **Mesh...** category) is a nondimensional parameter calculated using the volume deviation method, and is defined as

$$\frac{(\text{optimal-cell-size})-(\text{cell-size})}{(\text{optimal-cell-size})} \tag{33.4}$$

where optimal-cell-size is the size of an equilateral cell with the same circumradius. A value of 0 indicates a best case equilateral cell and a value of 1 indicates a completely degenerate cell. Degenerate cells (slivers) are characterized by nodes that are nearly coplanar (collinear in 2D). **Cell Equivolume Skew** applies only to triangular and tetrahedral elements.

Cell Id

(in the **Cell Info...** category) is a unique integer identifier associated with each cell.

Cell Info...

includes quantities that identify the cell and its relationship to other cells.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS Fluent, the partition ID can be used to determine the extent of the various groups of cells.

Cell Refine Level

(in the **Adaption...** category) is an integer that indicates the number of times a cell has been subdivided in the hanging node adaption process, compared with the original mesh. For example, if one quad cell is split into four quads, the **Cell Refine Level** for each of the four new quads will be 1. If the resulting four quads are split again, the **Cell Refine Level** for each of the resulting 16 quads will be 2.

Cell Reynolds Number

(in the **Velocity...** category) is the value of the Reynolds number in a cell. (Reynolds number is a dimensionless parameter that is the ratio of inertia forces to viscous forces.) **Cell Reynolds Number** is defined as

$$Re \equiv \frac{\rho u d}{\mu} \tag{33.5}$$

where ρ is density, u is velocity magnitude, μ is the effective viscosity (laminar plus turbulent), and d is **Cell Volume** $^{1/2}$ for 2D cases and **Cell Volume** $^{1/3}$ in 3D or axisymmetric cases.

Cell Surface Area

(in the **Adaption...** category) is the total surface area of the cell, and is computed by summing the area of the faces that compose the cell.

Cell Volume

(in the **Mesh...** category) is the volume of a cell. In 2D the volume is the area of the cell multiplied by the unit depth. For axisymmetric cases, the cell volume is calculated using a reference depth of 1 radian. The unit quantity of **Cell Volume** is **volume**.

Cell Volume Derivative

(in the **Mesh...** category) is the change of a cell volume over time.

Cell Volume Error

(in the **Mesh...** category) is the cell volume over the unsteady cell volume.

2D Cell Volume

(in the **Mesh...** category) is the two-dimensional volume of a cell in an axisymmetric computation. For an axisymmetric computation, the 2D cell volume is scaled by the radius. Its unit quantity is **area**.

Cell Volume Change

(in the **Adaption...** category) is the maximum volume ratio of the current cell and its neighbors.

Cell Wall Distance

(in the **Mesh...** category) is the distribution of the normal distance of each cell centroid from the wall boundaries. Its unit quantity is **length**.

Cell Warpage

(in the **Adaption...** category) is the square root of the ratio of the distance between the cell centroid and cell circumcenter and the circumcenter radius:

$$\text{warpage} = \sqrt{\frac{\left|\vec{r}_{centroid} - \vec{r}_{circumcenter}\right|}{R_{circumcenter}}} \tag{33.6}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cell Zone Index

(in the **Cell Info...** category) is the integer cell zone identification number. In problems that have more than one cell zone, the cell zone ID can be used to identify the various groups of cells.

Cell Zone Type

(in the **Cell Info...** category) is the integer cell zone type ID. A fluid cell has a type ID of 1, a solid cell has a type ID of 17, and an exterior cell (parallel solver) has a type ID of 21.

Compressibility Factor

(in the **Properties...** category) is the ratio of the ideal gas density of the fluid divided by the real gas fluid density in the same flow conditions. Compressibility Factor is defined as

$$Z=\frac{P/RT}{\rho} \tag{33.7}$$

where Z is the compressibility factor, P is the absolute pressure, T is the temperature, and $R=R_u/MW$ (the universal gas constant R_u divided by the molecular weight MW). The compressibility factor is available only with the real gas models.

Contact Resistivity

(in the **Solidification/Melting...** category) is the additional resistance at the wall due to contact resistance. It is equal to $R_c\left(1-\beta\right)/h$, where R_c is the contact resistance, β is the liquid fraction, and h is the cell height of the wall-adjacent cell. The unit quantity for **Contact Resistivity** is **thermal-resistivity**.

Critical Pressure

(in the **Properties...** category) is the mixture critical pressure. This property is available when a composition dependent option is selected for critical pressure in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Critical Specific Volume

(in the **Properties...** category) is the mixture critical specific volume. This property is available when a composition dependent option is selected for critical specific volume in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Critical Strain Rate

(in the **Premixed Combustion...** category) is a parameter that takes into account the stretching and extinction of premixed flames (g_{cr} in Equation 9.18 in the Theory Guide). Its unit quantity is **time-inverse**.

Critical Temperature

(in the **Properties...** category) is the mixture critical temperature. This property is available when a composition dependent option is selected for critical temperature in the cases with Aungier-Redlich-Kwong real gas model and species transport

Current Magnitude

(in the **Potential...** category) is the magnitude of the electric current vector in the field, $\left|\sigma\nabla\varphi\right|$.

Curvature Correction Function fr

(in the **Turbulence...** category) is the multiplier of the production term when curvature correction is selected for Spalart-Allmaras or two equation models. See Curvature Correction for the Spalart-Allmaras and Two-Equation Models in the *Fluent Theory Guide* for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Custom Field Functions...
are scalar field functions defined by you. You can create a custom function using the Custom Field Function Calculator Dialog Box (p. 2683). All defined custom field functions will be listed in the lower drop-down list. See Custom Field Functions (p. 2003) for details.

Damkohler Number
(in the **Premixed Combustion...** category) is a nondimensional parameter that is defined as the ratio of turbulent to chemical time scales.

Density...
includes variables related to density.

Density
(in the **Density...** category) is the mass per unit volume of the fluid. Plots or reports of **Density** include only fluid cell zones. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. The unit quantity for **Density** is **density**.

Density All
(in the **Density...** category) is the mass per unit volume of the fluid or solid material. Plots or reports of **Density All** include both fluid and solid cell zones. The unit quantity for **Density All** is **density**.

Derivatives...
are the viscous derivatives. For example, **dX-Velocity/dx** is the first derivative of the x component of velocity with respect to the x-coordinate direction. You can compute first derivatives of velocity, angular velocity, and pressure in the pressure-based solver, and first derivatives of velocity, angular velocity, temperature, and species in the density-based solvers.

DES Length Scale
(in the **Turbulence...** category) is available when you keep the temporary solver memory from being freed using the `solve/set/expert` text command. It is defined by Equation 4.250 in the Theory Guide for the Spalart-Allmaras based DES model and Equation 4.257 in the Theory Guide for the realizable k-epsilon based DES model. The DES length scale for the BSL / SST k-omega based DES model is defined by $C_{des}\Delta_{\max}=\left(\frac{L_t}{F_{DES}}\right)$, where C_{des} is a calibration constant used in the DES model and has a value of 0.61 and $\Delta_{\max}$ is the maximum local grid spacing ($\Delta x, \Delta y, \Delta z$).

DES TKE Dissipation Multiplier
(in the **Turbulence...** category) is either the multiplier function F_{DES} for Detached Eddy Simulation (DES) with BSL, SST, or Transition SST (see DES with the BSL or SST k-ω Model and DES with the Transition SST Model in the Theory Guide for details) or the function f_d for DES with Spalart-Allmaras or Realizable k-ε (see Theory Guide DES with the Spalart-Allmaras Model or DES with the Realizable k-ε Model, respectively).

Diameter
(in the **Properties...** category) is the diameter of particles, droplets, or bubbles of the secondary phase selected in the **Phase** drop-down list. Its unit quantity is **length**.

Diffusion Coef. of Scalar-n
(in the **User Defined Scalars...** category) is the diffusion coefficient for the n^{th} user-defined scalar transport equation. See the Fluent Customization Manual for details about defining user-defined scalars.

Discrete Phase Sources...
includes quantities related to the discrete phase model sources. See Modeling Discrete Phase (p. 1235) for details about this model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Discrete Phase Variables...
includes non-source quantities related to the discrete phase model. See Modeling Discrete Phase (p. 1235) for details about this model.

DPM Absorption Coefficient
(in the **Discrete Phase Variables...** category) is the absorption coefficient for discrete-phase calculations that involve radiation (a in Equation 5.17 in the Theory Guide). Its unit quantity is **length-inverse**.

DPM Accretion
(in the **Discrete Phase Variables...** category) is the accretion rate calculated at a wall boundary:

$$R_{accretion} = \sum_{p=1}^{N} \frac{\dot{m}_p}{A_{face}} \tag{33.8}$$

where $\dot{m}_p$ is the mass flow rate of the particle stream, and A_{face} is the area of the wall face where the particle strikes the boundary. This item will appear only if the optional erosion/accretion model is enabled. See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. The unit quantity for **DPM Accretion** is **mass-flux**.

DPM Burnout
(in the **Discrete Phase Sources...** category) is the exchange of mass from the discrete to the continuous phase for the combustion law (Law 5) and is proportional to the solid phase reaction rate. The burnout exchange has units of **mass-flow** and is reported as the rate occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM Collision Rate
(in the **Discrete Phase Variables...** category) is the time rate of particle-to-particle collisions per unit volume. Its unit quantity is **collision-rate**.

DPM Concentration
(in the **Discrete Phase Variables...** category) is the total concentration of the particles in all phases in a cell. Its unit quantity is **density**.

DPM Conc of <*component*>
(in the **Discrete Phase Variables...** category) is the mean concentration of <*component*> in the particles within a cell, computed per phase. Therefore, when using DDPM, this quantity appears for each combination of <*component*> and discrete particle phase (including the mixture phase). Its unit quantity is **density**.

DPM Density
(in the **Discrete Phase Variables...** category) is the mean particle density. This is computed as the mean density of the particles in each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **density**.

DPM Diameter
(in the **Discrete Phase Variables...** category) is the mean particle diameter. This is computed as the mean diameter of the discrete phase particles in each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **length**.

DPM Emission
(in the **Discrete Phase Variables...** category) is the amount of radiation emitted by a discrete-phase particle per unit volume. Its unit quantity is **heat-generation-rate**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DPM Enthalpy Source

(in the **Discrete Phase Sources...** category) is the exchange of enthalpy (sensible enthalpy plus heat of formation) from the discrete phase to the continuous phase. The exchange is positive when the particles are a source of heat in the continuous phase. The unit quantity for **DPM Enthalpy Source** is **power** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM Erosion Rate (Generic)

(in the **Discrete Phase Variables...** category) is the erosion rate calculated at a wall boundary face using Equation 16.308 in the *Fluent Theory Guide* based on the values entered in the **Generic Erosion Model Parameters** dialog box (see Setting Particle Erosion and Accretion Parameters (p. 1309)). This item will appear only if the **Erosion/Accretion** option is selected in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278) and the **Generic Model** option is enabled in the **DPM** tab of the Wall Dialog Box (p. 2456). See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. The unit quantity for **DPM Erosion Rate (Generic)** is **mass-flux**.

DPM Erosion Rate (Finnie)

(in the **Discrete Phase Variables...** category) is the Finnie erosion rate calculated using the Finnie formulation. (See Accretion in the *Fluent Theory Guide* for background information about this model.) This item will appear only if the **Finnie** option is enabled in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278). See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. The unit quantity for **DPM Erosion Rate (Finnie)** is **mass-flux**.

DPM Erosion Rate (McLaury)

(in the **Discrete Phase Variables...** category) is the McLaury erosion rate calculated using the McLaury formulation. (See McLaury Erosion Model in the *Fluent Theory Guide* for background information about this model.) This item will appear only if the **McLaury** erosion model is enabled in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278). See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. The unit quantity for **DPM Erosion Rate (McLaury)** is **mass-flux**.

DPM Erosion Rate (Oka)

(in the **Discrete Phase Variables...** category) is the Oka erosion rate calculated using the Oka formulation. (See Oka Erosion Model in the *Fluent Theory Guide* for background information about this model.) This item will appear only if the **Oka** erosion model is enabled in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278). See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. The unit quantity for **DPM Erosion Rate (Oka)** is **mass-flux**.

DPM Evaporation/Devolatilization

(in the **Discrete Phase Sources...** category) is the exchange of mass, due to droplet-particle evaporation or combusting-particle devolatilization, from the discrete phase to the evaporating or devolatilizing species. If you are not using the non-premixed combustion model, the mass source for each individual species (**DPM species-n Source**, below) is also available; for non-premixed combustion, only this sum is available. The unit quantity for **DPM Evaporation/Devolatilization** is **mass-flow** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM Granular Temperature

(in the **Discrete Phase Variables...** category) is the mean Granular Temperature for the discrete phase particles within a cell. Its unit quantity is **turbulent kinetic energy**. This quantity is only available when using a granular secondary phase in the Dense Discrete Phase Model.

DPM Mass Source

(in the **Discrete Phase Sources...** category) is the total exchange of mass from the discrete phase to the continuous phase. The mass exchange is positive when the particles are a source of mass in the continuous

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

phase. If you are not using the non-premixed combustion model, **DPM Mass Source** will be equal to the sum of all species mass sources (**DPM species-n Source**, below); if you are using the non-premixed combustion model, it will be equal to **DPM Burnout** plus **DPM Evaporation/Devolatilization**. The unit quantity for **DPM Mass Source** is **mass-flow** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM D20

(in the **Discrete Phase Variables...** category) is the mean D20 diameter for the discrete phase particles within a cell. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **length**. For the definition of D20 diameter, refer to Summary Reporting of Current Particles (p. 1358).

DPM D30

(in the **Discrete Phase Variables...** category) is the mean D30 diameter for the discrete phase particles within a cell. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **length**. For the definition of D30 diameter, refer to Summary Reporting of Current Particles (p. 1358).

DPM D32

(in the **Discrete Phase Variables...** category) is the mean Sauter diameter for the discrete phase particles within a cell. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **length**. For the definition of Sauter diameter, refer to Summary Reporting of Current Particles (p. 1358).

DPM Number Density

(in the **Discrete Phase Variables...** category) is the number of particles per unit cell volume. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **volume-inverse**.

DPM Parcels in Cell

(in the **Discrete Phase Variables...** category) is the number of discrete phase parcels in each cell. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase.

DPM Particles in Cell

(in the **Discrete Phase Variables...** category) is the number of discrete phase particles in each cell. This is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase.

DPM RMS Diameter

(in the **Discrete Phase Variables...** category) is the RMS particle diameter. This is computed as the RMS particle diameter within each cell and is computed per phase. Therefore, when using DDPM, this quantity is available for each discrete phase and the mixture phase. Its unit quantity is length.

DPM RMS Temperature

(in the **Discrete Phase Variables...** category) is the RMS particle temperature. This is computed as the RMS particle temperature within each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **temperature**.

DPM RMS X, Y, Z Velocity

(in the **Discrete Phase Variables...** category) are the RMS X, Y, and Z Velocity components of the discrete phase. These are computed as the mean discrete phase RMS velocities and are computed per phase.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Therefore, when using DDPM these quantities are available for each discrete phase and the mixture phase. Its unit quantity is **velocity**.

DPM Scattering

(in the **Discrete Phase Variables...** category) is the scattering coefficient for discrete-phase calculations that involve radiation (σ_s in Equation 5.17 in the Theory Guide). Its unit quantity is **length-inverse**.

DPM Sensible Enthalpy Source

(in the **Discrete Phase Sources...** category) is the exchange of sensible enthalpy from the discrete phase to the continuous phase. The exchange is positive when the particles are a source of heat in the continuous phase. Its unit quantity is **power** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM species-n Source

(in the **Discrete Phase Sources...** category) is the exchange of mass, due to droplet-particle evaporation or combusting-particle devolatilization, from the discrete phase to the evaporating or devolatilizing species. (The name of the species will replace **species-n** in **DPM species-n Source**.) These species can be specified in the Set Injection Properties Dialog Box (p. 2796), and their descriptions can be found in Defining Injection Properties (p. 1286). The unit quantity is **mass-flow** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases. Note that this variable will not be available if you are using the non-premixed combustion model; use **DPM Evaporation/Devolatilization** instead.

DPM Specific Heat

(in the **Discrete Phase Variables...** category) is the mean particle specific heat. This is computed as the mean specific heat of the particles within each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **specific-heat**.

DPM Swirl Momentum Source

(in the **Discrete Phase Sources...** category) is the exchange of swirl momentum from the discrete phase to the continuous phase. This value is positive when the particles are a source of momentum in the continuous phase. The unit quantity is **force** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

DPM Temperature

(in the **Discrete Phase Variables...** category) is the mean particle temperature. This is computed as the mean temperature of the particles within each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase. Its unit quantity is **temperature**.

DPM Volume Fraction

(in the **Discrete Phase Variables...** category) is the volume fraction of the discrete phase. This is computed as the mean discrete phase volume fraction within each cell and is computed per phase. Therefore, when using DDPM this quantity is available for each discrete phase and the mixture phase.

DPM X, Y, Z Momentum Source

(in the **Discrete Phase Sources...** category) are the exchange of x-, y-, and z-direction momentum from the discrete phase to the continuous phase. These values are positive when the particles are a source of momentum in the continuous phase. The unit quantity is **force** and is reported as the rate of exchange occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DPM X, Y, Z Velocity

(in the **Discrete Phase Variables...** category) are the X, Y, and Z Velocity components of the discrete phase. These are computed as the mean discrete phase velocities and are computed per phase. Therefore, when using DDPM these quantities are available for each discrete phase and the mixture phase. Its unit quantity is **velocity**.

DRG Reduced Number of Reactions

(in the **Reactions…** category) is the number of retained reactions in reduced mechanism. This variable quantifies the size of the reduced mechanism at each cell or particle in the domain.

DRG Reduced Number of Species

(in the **Species...** category) is the number of retained species in reduced mechanism. This variable quantifies the size of the reduced mechanism at each cell or particle in the domain.

Dynamic Cell Volume Change

(in the **Mesh...** category) is the change of a cell volume.

Dynamic Pressure

(in the **Pressure...** category) is defined as $q \equiv \frac{1}{2}\rho v^2$. Its unit quantity is **pressure**.

Echem Reaction Rate of Reaction-n

(in the **Reactions...** category) is the n^{th} electrochemical reaction rate. This quantity is only available if the electrochemical reaction model is enabled.

Eff Diff Coef of species-n

(in the **Species...** category) is the sum of the laminar and turbulent diffusion coefficients of a species into the mixture:

$$D_{i,m} + \frac{\mu_t}{\rho Sc_t} \tag{33.9}$$

(The name of the species will replace **species-n** in **Eff Diff Coef of species-n**.) The unit quantity is **mass-diffusivity**.

Effective Prandtl Number

(in the **Turbulence...** category) is the ratio $\mu_{eff} c_p / k_{eff}$, where μ_{eff} is the effective viscosity, c_p is the specific heat, and k_{eff} is the effective thermal conductivity.

Effective Thermal Conductivity

(in the **Properties...** category) is the sum of the laminar and turbulent thermal conductivities, $k + k_t$, of the fluid. A large thermal conductivity is associated with a good heat conductor and a small thermal conductivity with a poor heat conductor (good insulator). Its unit quantity is **thermal-conductivity**.

Effective Viscosity

(in the **Turbulence...** category) is the sum of the laminar and turbulent viscosities of the fluid. Viscosity, μ, is defined by the ratio of shear stress to the rate of shear. Its unit quantity is **viscosity**.

Electric Potential

(in the **Potential...** category) is the electric potential φ used in Equation 7.92 in the *Fluent Theory Guide*.

Electric Conductivity

(in the **Properties...** category) is the electric conductivity σ used in Equation 7.80 in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Electrode Surface Potential

(in the **Potential...** category) is the electric potential on the electrode surface at an external Faradaic interface (φ_{ed} in the Butler-Volmer Equation 7.82 in the *Fluent Theory Guide*).

Enthalpy

(in the **Temperature...** category) is defined differently for compressible and incompressible flows, and depending on the solver and models in use.

For compressible flows,

$$H=\sum_j Y_j H_j \tag{33.10}$$

and for incompressible flows,

$$H=\sum_j Y_j H_j+\frac{p}{\rho} \tag{33.11}$$

where Y_j and H_j are, respectively, the mass fraction and enthalpy of species j. (See **Enthalpy of species-n**, below). For the pressure-based solver, the second term on the right-hand side of Equation 33.11 (p. 1970) is included only if the pressure work term is included in the energy equation (see Inclusion of Pressure Work and Kinetic Energy Terms in the Theory Guide). For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. For all reacting flow models, the **Enthalpy** plots consist of the thermal (or sensible) plus chemical energy. The unit quantity for **Enthalpy** is **specific-energy**.

In the case of the inert model (Using the Non-Premixed Model with the Inert Model in the Theory Guide), the enthalpy in a cell is split into the contributions from the inert and the reacting fractions of the gas phase species in the cell. The cell enthalpy is partitioned as

$$H=\gamma H_{inert}+\left(1-\gamma\right)H_{pdf} \tag{33.12}$$

where γ is the fraction of inert species in the cell. The quantity H_{inert} is the enthalpy of the inert species at the cell temperature, similarly H_{pdf} is the enthalpy of the active species at the cell temperature. It is assumed that the cell temperature is common to both inert and active species, so H_{inert}, H_{pdf} and the cell temperature are chosen so that Equation 33.12 (p. 1970) is satisfied.

Enthalpy of species-n

(in the **Species...** category) is defined differently depending on the solver and models options in use. The quantity:

$$H_j=\int_{T_{ref,j}}^{T} c_{p,j}dT+h_j^0\left(T_{ref,j}\right) \tag{33.13}$$

where $h_j^0\left(T_{ref,j}\right)$ is the formation enthalpy of species j at the reference temperature $\left(T_{ref,j}\right)$, is reported only for non-adiabatic PDF cases, or if the density-based solver is selected. The quantity:

$$h_j=\int_{T_{ref}}^{T} c_{p,j}dT \tag{33.14}$$

where $T_{ref}=298.15K$, is reported in all other cases. The unit quantity for **Enthalpy of species-n** is **specific-energy**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Entropy

(in the **Temperature...** category) is a thermodynamic property defined by the equation

$$\Delta S \equiv \int_{rev} \frac{\delta Q}{T} \tag{33.15}$$

$$\Delta S = C_p \ln\left(\frac{T}{T_{ref}}\right) - R \ln\left(\frac{P}{P_{ref}}\right) \tag{33.16}$$

the entropy is computed using the equation

$$\Delta S = C_p \ln\left(\frac{T}{T_{ref}}\right) \tag{33.17}$$

The unit quantity for entropy is **specific-heat**.

Important

Note that for the real gas models the entropy is computed accordingly by the appropriate equation of state formulation.

Existing Value

(in the **Adaption...** category) is the value that presently resides in the temporary space reserved for cell variables (that is, the last value that you displayed or computed).

Face Area Magnitude

(in the **Mesh...** category) is the magnitude of the face area vector for noninternal faces (that is, faces that only have `c0` and no `c1`). The values are stored on the face itself and used when required. This variable is intended only for zone surfaces and not for other surfaces created for postprocessing.

Face Handedness

(in the **Mesh...** category) is a parameter that is equal to one in cells that are adjacent to left-handed faces, and zero elsewhere. It can be used to locate mesh problems.

Faradaic Current Density

(in the **Potential...** category) is the electric current density produced by the electrochemical reaction at Faradaic interfaces (Equation 7.89 in the *Fluent Theory Guide*). Faradaic current density is positive if electric current flows from the electrode zone to the electrolyte zone, and negative if the electric current flows in the reverse direction.

Faradaic Heat Source

(in the **Potential...** category) is the energy source term due to the electrochemical reaction at Faradaic interfaces (Equation 7.94 in the *Fluent Theory Guide*).

Film Thickness

(in the **Eulerian Wall Film...** category) is the thickness of the wall film.

Film Mass

(in the **Eulerian Wall Film...** category) is the mass of the wall film.

Film Temperature

(in the **Eulerian Wall Film...** category) is the temperature of the wall film.

Film X-Velocity

(in the **Eulerian Wall Film...** category) is the x-component of the velocity of the wall film.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Film Y-Velocity
(in the **Eulerian Wall Film...** category) is the y-component of the velocity of the wall film.

Film Z-Velocity
(in the **Eulerian Wall Film...** category) is the z-component of the velocity of the wall film.

Film Velocity Magnitude
(in the **Eulerian Wall Film...** category) is the magnitude of the velocity of the wall film.

Film Effective Pressure
(in the **Eulerian Wall Film...** category) is the effective pressure of the wall film.

Film Surface X-Velocity
(in the **Eulerian Wall Film...** category) is the x-component of the surface velocity of the wall film.

Film Surface Y-Velocity
(in the **Eulerian Wall Film...** category) is the y-component of the surface velocity of the wall film.

Film Surface Z-Velocity
(in the **Eulerian Wall Film...** category) is the z-component of the surface velocity of the wall film.

Film Surface Velocity Magnitude
(in the **Eulerian Wall Film...** category) is the magnitude of the surface velocity of the wall film.

Film Surface Temperature
(in the **Eulerian Wall Film...** category) is the surface temperature of the wall film.

Film Passive Scalar
(in the **Eulerian Wall Film...** category) is the passive scalar for the wall film scalar equation.

Film Courant Number
(in the **Eulerian Wall Film...** category) is the Courant number of the wall film.

Film Weber Number
(in the **Eulerian Wall Film...** category) is the Weber number of the wall film.

Film Stripped Mass
(in the **Eulerian Wall Film...** category) is the cumulative mass of stripped wall film.

Film Stripped Diam
(in the **Eulerian Wall Film...** category) is the diameter of stripped wall film droplets.

Film DPM Mass Source
(in the **Eulerian Wall Film...** category) is the additional mass of discrete particles being absorbed into the wall film.

Film DPM Energy Source
(in the **Eulerian Wall Film...** category) is the additional energy of discrete particles being absorbed into the wall film.

Film DPM X-Momentum Source
(in the **Eulerian Wall Film...** category) is the x-component of any additional momentum of discrete particles being absorbed into the wall film.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Film DPM Y-Momentum Source

(in the **Eulerian Wall Film...** category) is the y-component of any additional momentum of discrete particles being absorbed into the wall film.

Film DPM Z-Momentum Source

(in the **Eulerian Wall Film...** category) is the z-component of any additional momentum of discrete particles being absorbed into the wall film.

Film X-Momentum Source

(in the **Eulerian Wall Film...** category) is the x-component of any additional momentum being absorbed into the wall film.

Film Y-Momentum Source

(in the **Eulerian Wall Film...** category) is the y-component of any additional momentum being absorbed into the wall film.

Fine Scale Mass Fraction of species-n

(in the **Species...** category) is the term Y_i^* in Equation 7.30 in the Theory Guide .

Fine Scale Temperature

(in the **Temperature...** category) is the temperature of the fine scales, which is calculated from the enthalpy when the reaction proceeds over the time scale (τ^* in Equation 7.29 in the Theory Guide), governed by the Kinetic rates of Equation 7.7 in the Theory Guide . Its unit quantity is **temperature**.

Fine Scale Transfer Rate

(in the **Species...** category) is the transfer rate of the fine scales, which is equal to the inverse of the time scale (τ^* in Equation 7.29 in the Theory Guide). Its unit quantity is **time-inverse**.

1-Fine Scale Volume Fraction

(in the **Species...** category) is a function of the fine scale volume fraction (ξ^* in Equation 7.28 in the Theory Guide). The quantity is subtracted from unity to make it easier to interpret.

Film Separated Mass

(in the **Eulerian Wall Film...** category) is the cumulative mass of separated wall film.

Fvar Prod

(in the **Pdf...** category) is the production term in the mixture fraction variance equation solved in the non-premixed combustion model (that is, the last two terms in Equation 8.5 in the Theory Guide).

Fvar2 Prod

(in the **Pdf...** category) is the production term in the secondary mixture fraction variance equation solved in the non-premixed combustion model. See Equation 8.5 in the Theory Guide .

Gas Constant (R)

(in the **Properties...** category) is the gas constant of the fluid. Its unit quantity is **specific-heat**.

Geometric Roughness Height

(in the **Turbulence...** category) is used in the roughness correlation of the Transition SST model. See Equation 4.187 in the Theory Guide.

Granular Conductivity

(in the **Properties...** category) is equivalent to the diffusion coefficient in Equation 17.321 in the Theory Guide . For more information, see Granular Temperature in the Theory Guide . Its unit quantity is kg/m-s.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Granular Pressure...

includes quantities for reporting the solids pressure for each granular phase (p_s in Equation 17.290 in the Theory Guide). See Solids Pressure in the Theory Guide for details. Its unit quantity is **pressure**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Granular Temperature...

includes quantities for reporting the granular temperature for each granular phase (Θ_s in Equation 17.321 in the Theory Guide). See Granular Temperature in the Theory Guide for details. Its unit quantity is m^2/s^2. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

HCN Density

(in the **NOx...** category) is the mass per unit volume of HCN. The unit quantity is **density**. The **HCN Density** will appear only if you are modeling fuel NOx. See Fuel NOx Formation in the Theory Guide for details.

Heat of Heterogeneous Reaction

(in the **Phase Interaction...** category) is the heat added or removed due to heterogeneous chemical reactions. For exothermic reactions the **Heat of Heterogeneous Reaction** is reported as a positive quantity, while for endothermic reactions it will be a negative quantity. If you have more than one heterogeneous reaction defined in your case, the **Heat of Heterogeneous Reaction** reported is the sum of the heat for all heterogeneous reactions. The unit quantity of **Heat of Heterogeneous Reaction** is Watt.

Heat of Reaction

(in the **Reactions...** category) is the heat added or removed due to chemical reactions. The quantity reported by Fluent is the volumetric heat of reaction, as defined in Equation 5.10 in the Theory Guide multiplied by the cell volume. For exothermic reactions, the heat of reaction is reported as a positive quantity, while for endothermic reactions it is reported as a negative quantity. If you have more than one reaction defined in your case, the **Heat of Reaction** reported is the sum of the heat for all reactions. The unit of measurement for the heat of reaction is Watts. The **Heat of Reaction** is not available for the non-premixed and partially-premixed models.

Helicity

(in the **Velocity...** category) is defined by the dot product of vorticity and the velocity vector.

$$H=\left(\nabla\times\vec{V}\right)\cdot\vec{V} \tag{33.18}$$

Vorticity is a measure of the rotation of a fluid element as it moves in the flow field.

Incident Radiation

(in the **Radiation...** category) is the total radiation energy, G, that arrives at a location per unit time and per unit area:

$$G=\int_{\Omega=4\pi} I d\Omega \tag{33.19}$$

where I is the radiation intensity and Ω is the solid angle. G is the quantity that the P-1 radiation model computes. For the DO radiation model, the incident radiation is computed over a finite number of discrete solid angles, each associated with a vector direction. The unit quantity for **Incident Radiation** is **heat-flux**.

Incident Radiation (Band n)

(in the **Radiation...** category) is the radiation energy contained in the wavelength band $\Delta\lambda$ for the non-gray P-1 radiation model or the non-gray DO radiation model. Its unit quantity is **heat-flux**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interface Overlap Fraction

(in the **mesh** category) is a metric for measuring the quality of the intersection between interface zones for non-conformal interfaces. It is calculated on each element of the interface zone and ranges from 0 to 1, where 0 means no intersection, and 1 means full intersection.

Intermittency

(in the **Turbulence...** category) is a measure of the probability that a given point is located inside a turbulent region. Upstream of transition the intermittency is zero. Once the transition occurs, the intermittency is ramped up to one until the fully turbulent boundary layer regime is achieved.

Intermittency Effective

(in the **Turbulence...** category) is used in the coupling of the Transition model and the SST Transport equations (see Coupling the Transition Model and SST Transport Equations in the Theory Guide for details).

Internal Energy

(in the **Temperature...** category) is the summation of the kinetic and potential energies of the molecules of the substance per unit volume (and excludes chemical and nuclear energies). **Internal Energy** is defined as $e=c_v T$. Its unit quantity is **specific-energy**.

Jet Acoustic Power

(in the **Acoustics...** category) is the acoustic power for turbulent axisymmetric jets (see Equation 15.15 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Jet Acoustic Power Level (dB)

(in the **Acoustics...** category) is the acoustic power for turbulent axisymmetric jets, reported in dB (see Equation 15.28 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Joule Heat Source

(in the **Potential...** category) is the energy source term due to the Joule heating (Equation 20.2 in the *Fluent Theory Guide*).

Kinetic Rate of Reaction-n

(in the **Reactions...** category) is given by the following expression (see Equation 7.7 in the Theory Guide for definitions of the variables shown here):

$$\hat{R}_r = \Gamma \left(k_{f,r} \prod_{j=1}^{N_r} [C_{j,r}]^{\eta'_{j,r}} - k_{b,r} \prod_{j=1}^{N_r} [C_{j,r}]^{\eta''_{j,r}} \right) \tag{33.20}$$

The reported value is independent of any particular species, and has units of kmol/m^3-s.

To find the rate of production/destruction for a given species i due to reaction r, multiply the reported reaction rate for reaction r by the term $M_i\left(\nu''_{i,r} - \nu'_{i,r}\right)$, where M_i is the molecular weight of species i, and $\nu''_{i,r}$ and $\nu'_{i,r}$ are the stoichiometric coefficients of species i in reaction r.

For particle reactions it is the global rate of the particle reaction n expressed in kmol/s/m3. This is computed as

$$\frac{\overline{R}_{j,r}}{M_j V}$$

where $\overline{R}_{j,r}$ is the rate of particle species depletion (or generation) given by Equation 7.69 in the Theory Guide , M_j is the particle species molecular weight, and V is the cell volume.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lam Diff Coef of species-n
(in the **Species...** category) is the laminar diffusion coefficient of a species into the mixture, $D_{i,m}$. Its unit quantity is **mass-diffusivity**.

Laminar Flame Speed
(in the **Premixed Combustion...** category) is the propagation speed of laminar premixed flames (U_l in Equation 9.9 in the Theory Guide). Its unit quantity is **velocity**.

Laminar Kinetic Energy (kl)
(in the **Turbulence...category**) is a measure of the "laminar" streamwise fluctuations present in the pre-transitional region of the boundary layer subjected to free-stream turbulence. A transport equation of kl is considered by the k-kl-omega transition model.

LEE Self-Noise X-Source, LEE Self-Noise Y-Source, LEE Self-Noise Z-Source
(in the **Acoustics...** category) are the self-noise source terms in the linearized Euler equation for the acoustic velocity component (see Equation 15.33 in the Theory Guide). They are available only when the **Broadband Noise Sources** acoustics model is being used.

LEE Shear-Noise X-Source, LEE Shear-Noise Y-Source, LEE Shear-Noise Z-Source
(in the **Acoustics...** category) are the shear-noise source terms in the linearized Euler equation for the acoustic velocity component (see Equation 15.33 in the Theory Guide). They are available only when the **Broadband Noise Sources** acoustics model is being used.

LEE Total Noise X-Source, LEE Total Noise Y-Source, LEE Total Noise Z-Source
(in the **Acoustics...** category) are the total noise source terms in the linearized Euler equation for the acoustic velocity component (see Equation 15.33 in the Theory Guide). The total noise source term is the sum of the self-noise and shear-noise source terms. They are available only when the **Broadband Noise Sources** acoustics model is being used.

LES Subgrid Turbulent Viscosity
(in the **Turbulence...** category) is the eddy viscosity that is determined by the local algebraic sub-grid scale model in an embedded LES zone, which actually affects the momentum transport equations (see Embedded Large Eddy Simulation (ELES) in the Theory Guide). Its unit quantity is **viscosity**.

Lilley's Self-Noise Source
(in the **Acoustics...** category) is the self-noise source term in the linearized Lilley's equation (see Equation 15.37 in the Theory Guide), available only when the **Broadband Noise Sources** acoustics model is being used.

Lilley's Shear-Noise Source
(in the **Acoustics...** category) is the shear-noise source term in the linearized Lilley's equation (see Equation 15.37 in the Theory Guide), available only when the **Broadband Noise Sources** acoustics model is being used.

Lilley's Total Noise Source
(in the **Acoustics...** category) is the total noise source term in the linearized Lilley's equation (see Equation 15.37 in the Theory Guide). The total noise source term is the sum of the self-noise and shear-noise source terms, available only when the **Broadband Noise Sources** acoustics model is being used.

Liquid Fraction
(in the **Solidification/Melting...** category) is the liquid fraction β computed by the solidification/melting model:

$$\beta = \frac{\Delta H}{L} = 0 \quad if \quad T < T_{solidus} \tag{33.21}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\beta = \frac{\Delta H}{L} = 1 \quad if \quad T > T_{liquidus} \tag{33.22}$$

$$\beta = \frac{\Delta H}{L} = \frac{T - T_{solidus}}{T_{liquidus} - T_{solidus}} \quad if \quad T_{solidus} < T < T_{liquidus} \tag{33.23}$$

log10(Shape Sensitivity Magnitude)

(in the **Sensitivities...** category) provides a convenience function that plots $\log_{10}$ of the magnitude, in view of the large range of values possible for the shape sensitivity magnitude. This allows the importance of the surfaces in a domain to be ranked more easily based on how they affect the observation of interest when they are reshaped.

Mach Number

(in the **Velocity...** category) is the ratio of velocity and speed of sound.

Magnitude of Sensitivity to Body Forces

(in the **Sensitivities...** category) is the magnitude of the adjoint velocity primitive field normalized by cell volume. This field can be interpreted as the magnitude of the sensitivity of the observable to body force per unit volume. It can be used to identify regions in the domain where small changes to the momentum balance in the flow can have a large or small effect on the observable. This field is often observed to be large, for example, upstream of a body for which drag sensitivity is of interest, with the field diminishing in the upstream direction. This indicates the interference effect for an object positioned at various locations upstream of the object of interest. This field is normalized so that, in principle, it shows a mesh-independent quantity. In practice, this field has features that are often correlated with mesh structure. This is not unexpected. In fact, the adjoint solution field is providing very useful insight into regions of the flow domain where the observation of interest is potentially sensitive to particular features of the mesh and discretization process that affect the local momentum balance.

Magnitude of Sensitivity to Body Forces (Cell Values)

(in the **Sensitivities...** category) is the magnitude of the adjoint velocity primitive field. This field can be interpreted at the cell level as the sensitivity of the observable to a body force on the cell, or any factors that may change the momentum balance on the cell. As such it is a mesh-dependent quantity. This field is often observed to be large, for example, upstream of a body for which drag sensitivity is of interest, with the field diminishing in the upstream direction. This indicates the interference effect for an object positioned at various locations upstream of the object of interest.

Mark Poor Elements

(in the **Mesh...** category) is a parameter that is equal to one in cells that are identified as invalid or poor, as well as cells that are adjacent to the face of an invalid or poor cell, and zero elsewhere. It can be used to mark and/or display invalid and poor elements.

Mass fraction of HCN, Mass fraction of NH3, Mass fraction of NO, Mass fraction of N2O

(in the **NOx...** category) are the mass of HCN, the mass of NH_3, the mass of NO, and the mass of N_2O per unit mass of the mixture (for example, kg of HCN in 1 kg of the mixture). The **Mass fraction of HCN** and the **Mass fraction of NH3** will appear only if you are modeling fuel NOx. See Fuel NOx Formation in the Theory Guide for details.

Mass fraction of nuclei

(in the **Soot...** category) is the number of particles per unit mass of the mixture (in units of particles $\times 10^{15}$/kg) The **Mass fraction of nuclei** will appear only if you use the two-step soot model. See Soot Formation (p. 1184) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mass fraction of soot

(in the **Soot...** category) is the mass of soot per unit mass of the mixture (for example, kg of soot in 1 kg of the mixture). See Soot Formation (p. 1184) for details.

Mass fraction of species-n

(in the **Species...** category) is the mass of a species per unit mass of the mixture (for example, kg of species in 1 kg of the mixture).

Mean *n*

(in the **Unsteady Statistics...** category) is the time-averaged value of a solution variable *n* (for example, **Static Pressure**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

Mean- *cff_n*

(in the **Unsteady Statistics...** category) is the time-averaged value of a custom field function *cff_n* (for example, **uns-custom-funtion-0**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

Mean DPM *n*

(in the **Unsteady DPM Statistics...** category) is the time-averaged value of a discrete phase variable *n* (for example, **Volume Fraction**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

Meridional Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate that follows the flow path from inlet to outlet. Its value varies from 0 to 1.

Mesh...

includes variables related to the mesh.

Mesh X-Velocity, Mesh Y-Velocity, Mesh Z-Velocity

(in the **Velocity...** category) are the vector components of the mesh velocity for moving-mesh problems (rotating or multiple reference frames, mixing planes, or sliding meshes). Its unit quantity is **velocity**.

Mixture Fraction Variance

(in the **Pdf...** category) is the variance of the mixture fraction solved for in the non-premixed combustion model. This is the second conservation equation (along with the mixture fraction equation) that the non-premixed combustion model solves. (See Definition of the Mixture Fraction in the Theory Guide .)

Modified Turbulent Viscosity

(in the **Turbulence...** category) is the transported quantity $\tilde{\nu}$ that is solved for in the Spalart-Allmaras turbulence model and in DES with the Spalart-Allmaras model (see Equation 4.15 in the Theory Guide). The turbulent viscosity, μ_t, is computed directly from this quantity using the relationship given by Equation 4.16 in the Theory Guide . Its unit quantity is **viscosity**.

Molar Concentration of species-n

(in the **Species...** category) is the moles per unit volume of a species. Its unit quantity is **concentration**.

Mole fraction of species-n

(in the **Species...** category) is the number of moles of a species in one mole of the mixture.

Mole fraction of HCN, Mole fraction of NH3, Mole fraction of NO, Mole fraction of N2O

(in the **NOx...** category) are the number of moles of HCN, NH_3, NO, and N_2O in one mole of the mixture. The **Mole fraction of HCN** and the **Mole fraction of NH3** will appear only if you are modeling fuel NOx. See Fuel NOx Formation in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mole fraction of soot

(in the **Soot...** category) is the number of moles of soot in one mole of the mixture.

Molecular Prandtl Number

(in the **Properties...** category) is the ratio $c_p \mu_{lam} / k_{lam}$.

Molecular Viscosity

(in the **Properties...** category) is the laminar viscosity of the fluid. Viscosity, μ, is defined by the ratio of shear stress to the rate of shear. Its unit quantity is **viscosity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. For granular phases, this is equivalent to the solids shear viscosity μ_s in Equation 17.307 in the Theory Guide .

Momentum Thickness Re ($Re_{\theta t}$)

(in the **Turbulence...** category) is based on the momentum thickness of the boundary layer. The SST transition model is considering a nonlocal empirical correlation for the value of $Re_{\theta t}$ in the free-stream, based on turbulence intensity, pressure gradient, and so on, and a transport equation to allow the free-stream value to diffuse into the boundary layer.

NH3 Density, NO Density, N2O Density

(in the **NOx...** category) are the mass per unit volume of NH_3, NO, and N_2O. The unit quantity for each is **density**. The **NH3 Density** will appear only if you are modeling fuel NOx. See Fuel NOx Formation in the Theory Guide for details.

Non-Equilibrium Thermal Model Source

(in the **Temperature...** category) is the scaled value of thermal conductivity for the fluid zone (γk_f) or for the overlapping solid zone ($(1-\gamma)k_s$), where γ is the porosity, k_f is the fluid phase thermal conductivity (including the turbulent contribution, k_t), and k_s is the solid medium thermal conductivity. These terms can be seen in Equation 6.14 (p. 266) and Equation 6.15 (p. 266).

See Non-Equilibrium Thermal Model Equations (p. 265) and Non-Equilibrium Thermal Model (p. 277) for details about the non-equilibrium thermal model.

Normal Optimal Displacement

(in the **Sensitivities...** category) shows the normal component of the optimal displacement computed from the adjoint solution. This field is defined only for portions of walls lying within the control-volume specified for morphing. The size of the optimal displacement is determined by the scale factor that is chosen for the morphing. A positive value of displacement indicates that the surface will be displaced into the flow domain, whereas a negative value of displacement corresponds to wall movement outwards from the flow domain. This field eliminates the component of the optimal displacement vector that lies in the plane of the wall.

Normal Shape Sensitivity

(in the **Sensitivities...** category) shows the normal component of the shape sensitivity. A positive value indicates an orientation directed into the domain, while a negative value indicates that the shape sensitivity is oriented outwards from the domain. This field eliminates the component of the vector shape sensitivity field that lies in the plane of the wall.

Normalized Concentration of Nuclei

(in the **Soot...** category) is the normalized soot particle number density.

Normalized Q criterion

(in the **Turbulence...** category) is a postprocessing quantity used for visual inspection of turbulence structures.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Normalized Soot Aggregation Moments
(in the **Soot...** category) is the normalized soot aggregate moments. This quantity is available only with the Method of Moments model.

Normalized soot moments
(in the **Soot...** category) are the normalized soot moments. This quantity is available only with the Method of Moments model.

NOx...
contains quantities related to the NOx model. See NOx Formation (p. 1153) for details about this model.

Orthogonal Quality
(in the **Mesh...** category) is a measure of the quality of a mesh, and is computed for each cell using the vectors from the cell centroid to each of its faces, the area vectors of the cell's faces, and the vectors from the cell centroid to the centroids of each of the adjacent cells (see Equation 5.1 (p. 131) and Equation 5.2 (p. 131)). The worst cells will have an **Orthogonal Quality** closer to 0, with better cells closer to 1.

Overset Cell Type
(in the **Cell Info...** category) is an integer value indicating the overset cell type. Each cell can have one of the following values:

Cell Type	Integer Function Value
donor	2
solve	1
receptor	0
orphan	–1
dead	–2

Overset Donor Count
(in the **Cell Info...** category) shows the number of donor cells a receptor cell has for data interpolation. A value of zero indicates that the cell is not a receptor, or that the receptor cell is an orphan cell.

Overset Receptor Count
(in the **Cell Info...** category) shows the number of receptor cells referencing a donor cell. A value of zero indicates that the cell is not a donor cell.

Primary Particle Diameter
(in the **Soot...** category) is a soot primary particle diameter within soot aggregates. This quantity is available only with the Method of Moments model.

Partition Boundary Cell Distance
(in the **Mesh...** category) is the smallest number of cells that must be traversed to reach the nearest partition (interface) boundary.

Partition Neighbors
(in the **Cell Info...** category) is the number of adjacent partitions (that is, those that share at least one partition boundary face (interface)). It gives a measure of the number of messages that will have to be generated for parallel processing.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pdf...

contains quantities related to the non-premixed combustion model, which is described in Modeling Non-Premixed Combustion (p. 1025).

PDF Table Adiabatic Enthalpy

is the adiabatic enthalpy corresponding to the cell value of mixture fraction. For single mixture fraction cases it is given by the following equation:

$$H_{ad}=H_{fuel}f+H_{oxidizer}\left(1-f\right) \tag{33.24}$$

and for cases involving a secondary stream it is given by the following equation:

$$H_{ad}=H_{fuel}f+H_{secondary}f_{sec}+H_{oxidizer}\left(1-f_{sec}-f\right) \tag{33.25}$$

where

f = mixture fraction

f_{sec} = secondary mixture fraction

H_{fuel} = total enthalpy of the fuel stream

$H_{secondary}$ = total enthalpy of the secondary stream

$H_{oxidizer}$ = total enthalpy of the oxidizer stream

For adiabatic cases the **PDF Table Adiabatic Enthalpy** is equal to the value of Enthalpy. The unit of measurement is specific-energy.

PDF Table Heat Loss/Gain

is given by the following equation:

$$h_{loss}=\left(H-H_{min}\right)/\left(H_{ad}-H_{min}\right)-1 \tag{33.26}$$

if the cell enthalpy is less than the adiabatic enthalpy, and by the following equation:

$$h_{gain}=1-\left(H_{max}-H\right)/\left(H_{max}-H_{ad}\right) \tag{33.27}$$

if the cell enthalpy is higher than adiabatic

where

H = total enthalpy

H_{ad} = the PDF Table Adiabatic Enthalpy

H_{min} = the minimum Enthalpy defined in the PDF table

H_{max} = the maximum Enthalpy defined in the PDF table

The **PDF Table Heat Loss/Gain** is dimensionless and ranges in value from -1, when H is equal to H_{min}, to +1, when H is equal to H_{max}. If H is equal to the adiabatic enthalpy it will be 0.

Phases...

contains quantities for reporting the volume fraction of each phase. See Modeling Multiphase Flows (p. 1365) for details.

Pitchwise Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate in the circumferential (pitchwise) direction. Its value varies from 0 to 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Porous Deposition Rate of species-n
(in the **Species...** category) is the amount of a surface species that is deposited on porous zones. Its unit quantity is **mass-flux**.

Preconditioning Reference Velocity
(in the **Velocity...** category) is the reference velocity used in the coupled solver's preconditioning algorithm. See Preconditioning in the Theory Guide for details.

Premixed Combustion...
contains quantities related to the premixed combustion model, which is described in Modeling Premixed Combustion (p. 1089).

Pressure...
includes quantities related to a normal force per unit area (the impact of the gas molecules on the surfaces of a control volume).

Pressure Coefficient
(in the **Pressure...** category) is a dimensionless parameter defined by the equation

$$C_p = \frac{\left(p - p_{ref}\right)}{q_{ref}} \tag{33.28}$$

and q_{ref} is the reference dynamic pressure defined by $\frac{1}{2}\rho_{ref}v_{ref}{}^2$. The reference pressure, density, and velocity are defined in the Reference Values Task Page (p. 2502).

Pressure Spectrum Im *n*
(in the **Acoustics...** category) is the imaginary part of the complex Fourier amplitudes for Fourier mode *n*, as calculated by the Acoustic Sources FFT Dialog Box (p. 2549). See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details.

Pressure Spectrum Re *n*
(in the **Acoustics...** category) is the real part of the complex Fourier amplitudes for Fourier mode *n*, as calculated by the Acoustic Sources FFT Dialog Box (p. 2549). See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details.

Product Formation Rate
(in the **Premixed Combustion...** category) is the source term in the progress variable transport equation (S_c in Equation 9.1 in the Theory Guide). Its unit quantity is **time-inverse**.

Production of k
(in the **Turbulence...** category) is the rate of production of turbulence kinetic energy (times density). Its unit quantity is **turb-kinetic-energy-production**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Production of laminar k
(in the **Turbulence...** category) is the production of laminar kinetic energy used in the k-kl-ω transition model. See Transport Equations for the k-kl-ω Model in the Theory Guide for more details (Equation 4.148).

Progress Variable
(in the **Premixed Combustion...** category) is a normalized mass fraction of the combustion products ($c=1$) or unburnt mixture products ($c=0$), as defined by Equation 9.2 in the Theory Guide .

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Properties...
includes material property quantities for fluids and solids.

Q criterion
(in the **Turbulence...** category) is a postprocessing quantity used for visual inspection of turbulence structures.

Rate of Coagulation
(in the **Soot...** category) is the rate of the coagulation of soot particles.

Rate of NO
(in the **NOx...** category) is the overall rate of formation of NO due to all active NO formation pathways (for example, thermal, prompt, and so on).

Rate of Nucleation
(in the **Soot...** category) is the rate of nucleation of the soot particles.

Rate of Nuclei
(in the **Soot...** category) is the overall rate of formation of nuclei.

Rate of N2OPath NO
(in the **NOx...** category) is the rate of formation of NO due to the N_2O pathway only (only available when N_2O pathway is active).

Rate of Oxidation
(in the **Soot...** category) is the rate of oxidation of the soot particles.

Rate of Prompt NO
(in the **NOx...** category) is the rate of formation of NO due to the prompt pathway only (only available when prompt pathway is active).

Rate of Reburn NO
(in the **NOx...** category) is the rate of formation of NO due to the reburn pathway only (only available when reburn pathway is active).

Rate of SNCR NO
(in the **NOx...** category) is the rate of formation of NO due to the SNCR pathway only (only available when SNCR pathway is active).

Rate of Soot
(in the **Soot...** category) is the overall rate of formation of soot mass.

Rate of Soot Mass Nucleation
(in the **Soot...** category) is the overall rate of soot nucleation.

Rate of Surface Growth
(in the **Soot...** category) is the rate of the soot particle surface growth due to reactions at soot particle surface.

Rate of Thermal NO
(in the **NOx...** category) is the rate of formation of NO due to the thermal pathway only (only available when thermal pathway is active).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rate of Fuel NO

(in the **NOx...** category) is the rate of formation of NO due to the fuel pathway only (only available when fuel pathway is active).

Rate of USER NO

(in the **NOx...** category) is the rate of formation of NO due to user defined rates only (only available when user-defined function rates are added).

Radial Coordinate

(in the **Mesh...** category) is the length of the radius vector in the polar coordinate system. The radius vector is defined by a line segment between the node and the axis of rotation. You can define the rotational axis in the Fluid Dialog Box (p. 2369). (See also Velocity Reporting Options (p. 1933).) The unit quantity for **Radial Coordinate** is **length**.

Radial Pull Velocity

(in the **Solidification/Melting...** category) is the radial-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Radial Velocity

(in the **Velocity...** category) is the component of velocity in the radial direction. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Radial Velocity** is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Radial-Wall Shear Stress

(in the **Wall Fluxes...** category) is the radial component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Radiation...

includes quantities related to radiation heat transfer. See Modeling Radiation (p. 845) for details about the radiation models available in ANSYS Fluent.

Radiation Heat Flux

(in the **Wall Fluxes...** category) is the rate of radiation heat transfer through the control surface. It is calculated by the solver according to the specified radiation model. Heat flux out of the domain is negative, and heat flux into the domain is positive. The unit quantity for **Radiation Heat Flux** is **heat-flux**.

Radiation Intensity.Normalized Std Deviation

(in the **Radiation...** category) is the statistical standard deviation for the spherical mean radiation intensity.

Radiation Temperature

(in the **Radiation...** category) is the quantity θ_R, defined by

$$\theta_R = \left(\frac{G}{4\sigma}\right)^{1/4} \tag{33.29}$$

where G is the **Incident Radiation**. The unit quantity for **Radiation Temperature** is **temperature**.

Rate of Reaction-n

(in the **Reactions...** category) is the effective rate of progress of n^{th} reaction. For the finite-rate model, the value is the same as the **Kinetic Rate of Reaction-n**. For the eddy-dissipation model, the value is equivalent to the **Turbulent Rate of Reaction-n**. For the finite-rate/eddy-dissipation model, it is the lesser of the two.

For particle reactions it is the global rate of the particle reaction n expressed in kmol/s/m^3. This is computed as

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$\frac{\overline{R}_{j,r}}{M_j V}$

where $\overline{R}_{j,r}$ is the rate of particle species depletion (or generation) given by Equation 7.69 in the Theory Guide , M_j is the particle species molecular weight, and V is the cell volume.

Reactions...
includes quantities related to finite-rate reactions. See Modeling Species Transport and Finite-Rate Chemistry (p. 957) for information about modeling finite-rate reactions.

Reactor Net Mass Fraction of Species-n
(in the **Species...** category) is the mass of a species per unit mass of the mixture in the reactor network.

Reactor Net Temperature
(in the **Species...** category) is the computed temperature of the reactor network.

Reactor Net Zone ID
(in the **Species...** category) a unique identifier associated with each reactor network.

Reduced Temperature
(in the **Properties...** category) is the ratio T / T_c of the fluid temperature T divided by the critical temperature T_c. The reduced temperature T_r is available only with the Angier-Redlich-Kwong real gas model.

Reduced Pressure
(in the **Properties...** category) is the ratio P / P_c of the fluid pressure P divided by the critical pressure P_c. The reduced pressure P_r is available only with the Angier-Redlich-Kwong real gas model.

Reflected Radiation Flux (Band-n)
(in the **Wall Fluxes...** category) is the amount of radiative heat flux reflected by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Reflected Visible Solar Flux, Reflected IR Solar Flux
(in the **Wall Fluxes...** category) is the amount of solar heat flux reflected by a semi-transparent wall or porous jump boundary for a visible or infrared (IR) radiation.

Refractive Index
(in the **Radiation...** category) is a nondimensional parameter defined as the ratio of the speed of light in a vacuum to that in a material. See Specular Semi-Transparent Walls in the Theory Guide for details.

Relative Axial Velocity
(in the **Velocity...** category) is the axial-direction component of the velocity relative to the reference frame motion. See Velocity Reporting Options (p. 1933) for details. The unit quantity for **Relative Axial Velocity** is **velocity**.

Relative Humidity
(in the **Species...** category) is the ratio of the partial pressure of the water vapor actually present in an air-water mixture to the saturation pressure of water vapor at the mixture temperature. ANSYS Fluent computes the saturation pressure, p, from the following equation [93] (p. 2892):

$$\ln\left(\frac{p}{p_c}\right) = \left(\frac{T_c}{T} - 1\right) \times \sum_{i=1}^{8} F_i \left[a\left(T - T_p\right) \right]^{i-1} \tag{33.30}$$

where

p_c = 22.089 MPa

T_c = 647.286 K

$F_1 = -7.4192420$

$F_2 = 2.9721000 \times 10^{-1}$

$F_3 = -1.1552860 \times 10^{-1}$

$F_4 = 8.6856350 \times 10^{-3}$

$F_5 = 1.0940980 \times 10^{-3}$

$F_6 = -4.3999300 \times 10^{-3}$

$F_7 = 2.5206580 \times 10^{-3}$

$F_8 = -5.2186840 \times 10^{-4}$

a = 0.01

T_p = 338.15 K

Relative Mach Number

(in the **Velocity...** category) is the nondimensional ratio of the relative velocity and speed of sound.

Relative Radial Velocity

(in the **Velocity...** category) is the radial-direction component of the velocity relative to the reference frame motion. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Relative Radial Velocity** is **velocity**.

Relative Swirl Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity relative to the reference frame motion, in an axisymmetric swirling flow. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Relative Swirl Velocity** is **velocity**.

Relative Tangential Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity relative to the reference frame motion. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Relative Tangential Velocity** is **velocity**.

Relative Total Pressure

(in the **Pressure...** category) is the stagnation pressure computed using relative velocities instead of absolute velocities; that is, for incompressible flows the dynamic pressure would be computed using the relative velocities. (See Velocity Reporting Options (p. 1933) for more information about relative velocities.) The unit quantity for **Relative Total Pressure** is **pressure**.

Relative Total Temperature

(in the **Temperature...** category) is the stagnation temperature computed using relative velocities instead of absolute velocities. (See Velocity Reporting Options (p. 1933) for more information about relative velocities.) The unit quantity for **Relative Total Temperature** is **temperature**.

Relative Velocity Angle

(in the **Velocity...** category) is similar to the **Velocity Angle** except that it uses the relative tangential velocity, and is defined as

$$\tan^{-1}\left(-\frac{\text{relative-tangential-velocity}}{\text{axial-velocity}}\right) \tag{33.31}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Its unit quantity is **angle**.

Relative Velocity Magnitude

(in the **Velocity...** category) is the magnitude of the relative velocity vector instead of the absolute velocity vector. The relative velocity ($\vec{w}$) is the difference between the absolute velocity ($\vec{v}$) and the mesh velocity. For simple rotation, the relative velocity is defined as

$$\vec{w} \equiv \vec{v} - \vec{\Omega} \times \vec{r} \tag{33.32}$$

where $\vec{\Omega}$ is the angular velocity of a moving reference frame about the origin and $\vec{r}$ is the position vector. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Relative Velocity Magnitude** is **velocity**.

Relative X Velocity, Relative Y Velocity, Relative Z Velocity

(in the **Velocity...** category) are the x-, y-, and z-direction components of the velocity relative to the reference frame motion. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for these variables is **velocity**.

Residuals...

contains different quantities for the pressure-based and density-based solvers:

In the density-based solvers, this category includes the corrections to the primitive variables pressure, velocity, temperature, and species, as well as the time rate of change of the corrections to these primitive variables for the current iteration (that is, residuals). Corrections are the changes in the variables between the current and previous iterations and residuals are computed by dividing a cell's correction by its physical time step. The total residual for each variable is the summation of the Euler, viscous, and dissipation contributions. The dissipation components are the vector components of the flux-like, face-based dissipation operator.

In the pressure-based solver, only the **Mass Imbalance** in each cell is reported (unless you have requested others, as described in Postprocessing Residual Values (p. 1632)). At convergence, this quantity should be small compared to the average mass flow rate.

RMS (species-n) Mass Fraction

(in the **Species...** category) is the root mean square value of the mass of a species per unit mass of the mixture.

RMSE *n*

(in the **Unsteady Statistics...** category) is the root mean squared error value of a solution variable *n* (for example, **Static Pressure**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

RMSE- *cff_n*

(in the **Unsteady Statistics...** category) is the root mean squared error value of a custom field function *cff_n* (for example, **uns-custom-function-0**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

RMS DPM *n*

(in the **Unsteady DPM Statistics...** category) is the root mean square value of a discrete phase variable *n* (for example, **Volume Fraction**). See Postprocessing for Time-Dependent Problems (p. 1622) for details.

Rothalpy

(in the **Temperature...** category) is defined as

$$I = h + \frac{w^2}{2} - \frac{u^2}{2} \tag{33.33}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where h is the enthalpy, w is the relative velocity magnitude, and u is the magnitude of the rotational velocity $\vec{u}=\vec{\omega}\times\vec{r}$.

Scalar-n

(in the **User Defined Scalars...** category) is the value of the n^{th} scalar quantity you have defined as a user-defined scalar. See the Fluent Customization Manual for more information about user-defined scalars.

Scalar Dissipation

(in the **Pdf...** category) is one of two parameters that describes the species mass fraction and temperature for a laminar flamelet in mixture fraction spaces. It is defined as

$$\chi=2D\left|\nabla f\right|^2 \tag{33.34}$$

where f is the mixture fraction and D is a representative diffusion coefficient (see The Flamelet Concept in the Theory Guide for details). Its unit quantity is **time-inverse**.

Scattering Coefficient

(in the **Radiation...** category) is the property of a medium that describes the amount of scattering of thermal radiation per unit path length for propagation in the medium. It can be interpreted as the inverse of the mean free path that a photon will travel before undergoing scattering (if the scattering coefficient does not vary along the path). The unit quantity for **Scattering Coefficient** is **length-inverse**.

Secondary Mean Mixture Fraction

(in the **Pdf...** category) is the mean ratio of the secondary stream mass fraction to the sum of the fuel, secondary stream, and oxidant mass fractions. It is the secondary-stream conserved scalar that is calculated by the non-premixed combustion model. See Definition of the Mixture Fraction in the Theory Guide .

Secondary Mixture Fraction Variance

(in the **Pdf...** category) is the variance of the secondary stream mixture fraction that is solved for in the non-premixed combustion model. See Definition of the Mixture Fraction in the Theory Guide .

Sensible Enthalpy

(in the **Temperature...** category) is available when any of the species models are active and displays only the thermal (sensible) enthalpy.

Sensitivity to Body Force X-Component, Sensitivity to Body Force Y-Component, and Sensitivity to Body Force Z-Component

(in the **Sensitivities...** category) are the components of the adjoint velocity primitive field normalized by cell volume. This field can be interpreted as the magnitude of the sensitivity of the observable to components of a body force per unit volume. Consider a body force distribution, expressed as a force per unit volume. The integral of the vector product of that distribution with the components of this field gives a first-order estimate of the net effect of the body force on the observation.

Sensitivity to Body Force X-Component (Cell Values), Sensitivity to Body Force Y-Component (Cell Values), and Sensitivity to Body Force Z-Component (Cell Values)

(in the **Sensitivities...** category) are the components of the adjoint velocity primitive field. These fields show the sensitivity of the observable to the various components of a body force that may be applied to a cell, or other factors that may change the momentum balance on the cell. As such, it is a mesh-dependent quantity.

Sensitivity to Boundary Heat Flux

(in the **Sensitivities...** category) is available when the adjoint energy equation is solved and is defined on walls where a heat flux boundary condition is imposed. The field shows the sensitivity of the observation

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of interest to variations in the boundary heat flux through the wall. Its properties are analogous to those of Sensitivity to Boundary Temperature.

Sensitivity to Boundary Pressure

(in the **Sensitivities...** category) is defined on boundaries where there is a user-specified pressure as part of a boundary condition, such as on a pressure outlet. The field shows the sensitivity of the observation of interest to variations in the boundary pressure across the flow boundary. It is interesting to note that even though the original boundary condition specification may be for a uniform pressure on the domain boundary, the effect of a non-uniform pressure perturbation is available, The effect of any specific boundary pressure change can be estimated as an integral of the product of the change to the pressure with the plotted sensitivity field. Viewing this field will also indicate whether or not the assumption of a uniform pressure is adequate for the simulation.

Sensitivity to Boundary Temperature

(in the **Sensitivities...** category) is available when the energy adjoint equation is solved and is defined on boundaries where a temperature boundary condition is applied. This includes walls, velocity inlets, mass-flow inlets, pressure inlets, and pressure outlets where a backflow temperature may be specified. The field shows the sensitivity of the observation of interest to variations in the boundary temperature across the boundaries. Note that even if the original boundary condition specification is for a uniform temperature on the boundary, the effect of a non-uniform temperature perturbation is available. The effect of any specific boundary temperature change can be estimated as an integral of the product of the change to the temperature with the plotted sensitivity field. This field can be used to indicate whether or not the assumption of a uniform temperature is adequate for the simulation.

Sensitivity to Boundary X-Velocity, Sensitivity to Boundary Y-Velocity, and Sensitivity to Boundary Z-Velocity

(in the **Sensitivities...** category) are defined on those boundaries where a user-specification of a boundary velocity is made for the original flow calculation. This includes no-slip walls. The field shows how sensitive the observable of interest is to changes in the boundary velocity at any point. It is interesting to note that even though the original boundary condition specification may be for a uniform velocity on the domain boundary, the effect of a non-uniform velocity perturbation is available, The effect of any specific boundary velocity change can be estimated as an integral of the vector product of the change to the velocity with the plotted sensitivity field. A plot of this quantity on a velocity inlet, for example, can be very useful for assessing whether or not the inlet is positioned too close to key parts of the system. That is, it addresses the question of whether or not the flow domain is too small to achieve a successful computation of the performance measure of interest. Viewing this field will also indicate whether or not the assumption of a uniform inflow is adequate.

Sensitivity to Energy Sources

(in the **Sensitivities...** category) is available when the energy adjoint is solved and is the primitive adjoint temperature field normalized by cell volume. It can be interpreted at the cell level as the sensitivity of the observable with respect to thermal energy sources or sinks in the domain. This field is normalized so that, in principle, it is a mesh-independent quantity.

Sensitivity to Energy Sources (Cell Values)

(in the **Sensitivities...** category) is available when the energy adjoint is solved and is the primitive adjoint temperature field. It can be interpreted at the cell level as the sensitivity of the observable with respect to changes in the thermal energy balance of the cell. As such, it is a mesh-dependent quantity.

Sensitivity to Flow Blockage

(in the **Sensitivities...** category) is provided as a convenient tool for identifying portions of the flow domain where the introduction of blockages or obstructions in the flow can affect the observation of interest. Consider a blockage in the flow that generates a reaction force on the flow that is proportional to the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

local flow speed, and acting in the opposite direction to the local flow: $F=-\alpha(r)v$ where α is a local coefficient for the reaction force. The local contribution of this force on the observation of interest is determined by the vector product of this force with the adjoint velocity field. The flow blockage field that is plotted is $-v\cdot\tilde{v}$, namely the negative of the vector product of the flow velocity and the adjoint velocity (Cell Value).

Sensitivity to Mass Sources

(in the **Sensitivities...** category) is the primitive adjoint pressure field normalized by cell volume. This field can be interpreted as the sensitivity of the observable with respect to mass sources or sinks in the domain. Consider a mass source/sink distribution, expressed as mass flow rate per unit volume. The integral of that distribution, weighted by the local value of this field, gives the effect of the sources/sinks on the observation. This field is normalized so that, in principle, it shows a mesh-independent quantity. In practice, this field has features that are often correlated with mesh structure. This is not unexpected. In fact the adjoint solution field is providing very useful insight into regions of the flow domain where the observation of interest is potentially sensitive to particular features of the mesh and discretization process that affect local mass balance. When plotted on a boundary, this field indicates the effect of the addition or removal of fluid from the domain upon the quantity of interest. It is important to note that in this scenario the effect of the momentum of the fluid that is added or removed is not taken into account. The boundary velocity sensitivity should be plotted if that effect is also of interest.

Sensitivity to Mass Sources (Cell Values)

(in the **Sensitivities...** category) provides a plot of the primitive adjoint pressure field. This field can be interpreted at the cell level as the sensitivity of the observable with respect to any changes to the mass balance on the cell. As such, it is a mesh-dependent quantity.

Sensitivity to Viscosity

(in the **Sensitivities...** category) shows the sensitivity of the quantity of interest to variations in the turbulent effective viscosity for a turbulent problem, or the laminar viscosity in a laminar case. The sensitivity is normalized by the cell volume to account for cell size variations in the mesh.

Shape Sensitivity Magnitude

(in the **Sensitivities...** category) is the magnitude of the sensitivity of the observable with respect to a deformation applied to the mesh (both boundary and interior mesh). When plotted on the surface of a body the locations where this quantity is large indicates where small changes to the surface shape can have a large effect on the observable of interest. If the shape sensitivity magnitude is small then the effect of shape changes in this region can be expected to have a small effect on the observable of interest. When viewing this field, it is often observed that the magnitude varies by many orders of magnitude. Contour plots will clearly draw attention to regions with the highest sensitivity (often sharp edges and corners). However, it should be remembered that a relatively small surface movement that is distributed over a large area can have a cumulative effect that is large.

Shape Sensitivity X-Component, Shape Sensitivity Y-Component, and Shape Sensitivity Z-Component

(in the **Sensitivities...** category) are the individual components of the sensitivity of the observable of interest with respect to the mesh node locations. It is plotted as cell data and is computed as the average of the nodal sensitivities for a given cell, divided by the cell volume. Note that for this discrete adjoint solver the sensitivity of the result with respect to node locations both on and off boundaries is computed. The normalization by cell volume indicates that the fields that are plotted are the weighting factors for a continuous spatial deformation field. (Note that the nodal sensitivity data itself is used when mesh morphing is performed, and predictions about the effect of shape changes are made.)

Shielding Function for SBES or SDES

(in the **Turbulence...** category) is the shielding function f_{SDES} used as part of the Stress-Blended Eddy Simulation turbulence model and the Shielded Detached Eddy Simulation turbulence model. For details,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

see Stress-Blended Eddy Simulation (SBES) and Shielded Detached Eddy Simulation (SDES) in the *Fluent Theory Guide*, as well as Including the SDES or SBES Model with BSL, SST, and Transition SST Models (p. 805).

Skin Friction Coefficient

(in the **Wall Fluxes...** category) is a nondimensional parameter defined as the ratio of the wall shear stress and the reference dynamic pressure

$$C_f \equiv \frac{\tau_w}{\frac{1}{2}\rho_{ref} v_{ref}^2} \tag{33.35}$$

where τ_w is the wall shear stress, and ρ_{ref} and v_{ref} are the reference density and velocity defined in the Reference Values Task Page (p. 2502). For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Solar Heat Flux

(in the **Wall Fluxes...** category) is the rate of solar heat transfer through the control surface. Heat flux out of the domain is negative and heat flux into the domain is positive.

Solidification/Melting...

contains quantities related to solidification and melting.

Soot...

contains quantities related to the **Soot** model, which is described in Soot Formation (p. 1184).

Soot Density

(in the **Soot...** category) is the mass per unit volume of soot. The unit quantity is **density**. See Fuel NOx Formation in the Theory Guide for details.

Soot Mean Diameter

(in the **Soot...** category) is the average diameter of the soot particles. This quantity is available only with the Method of Moments model.

Soot Surface Area

(in the **Soot...** category) is the total surface area of the soot particles. This quantity is available only with the Method of Moments model.

Soot Volume fraction

(in the **Soot...** category) is the volume fraction of soot.

Sound Speed

(in the **Properties...** category) is the acoustic speed. It is computed from $\sqrt{\frac{\gamma p}{\rho}}$. Its unit quantity is **velocity**.

Important

Note that for the real gas models the sound speed is computed accordingly by the appropriate equation of state formulation.

Spanwise Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate in the spanwise direction, from hub to casing. Its value varies from 0 to 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

species-n Source Term
(in the **Species...** category) is the source term in each of the species transport equations due to reactions. The unit quantity is always kg/m^3-s.

Species...
includes quantities related to species transport and reactions.

Specific Dissipation Rate (Omega)
(in the **Turbulence...** category) is the rate of dissipation of turbulence kinetic energy in unit volume and time. Its unit quantity is **time-inverse**.

Specific Heat (Cp)
(in the **Properties...** category) is the thermodynamic property of specific heat at constant pressure. It is defined as the rate of change of enthalpy with temperature while pressure is held constant. Its unit quantity is **specific-heat**.

Specific Heat Ratio (gamma)
(in the **Properties...** category) is the ratio of specific heat at constant pressure to the specific heat at constant volume.

Spinodal Temperature
(in the **Properties...** category) is the temperature of the gas phase at which the derivative of pressure with respect to molar volume becomes positive. The spinodal temperature defines the point beyond which the equation of state is no longer valid. If the temperature of your case approaches the spinodal temperature in some regions, this indicates that the flow conditions in these regions probably fall inside the saturation dome. The **Spinodal Temperature** is available only with the Cubic Equation of State Real Gas models.

SPL for Octave Band at *x* Hz (dB)
(in the **Acoustics...** category) is the surface pressure level (in decibels) of the standard technical octave band at the octave central frequency *x*, as calculated by the Acoustic Sources FFT Dialog Box (p. 2549). See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details. Note that the transformation to the decibel units is done by default using the standard acoustic reference pressure value of 2 x 10^{-5} Pa; you can change this value using the Acoustics Model Dialog Box (p. 2289).

SPL for 1/3-Octave Band at *x* Hz (dB)
(in the **Acoustics...** category) is the surface pressure level (in decibels) of the standard technical 1/3-octave band at the 1/3-octave central frequency *x*, as calculated by the Acoustic Sources FFT Dialog Box (p. 2549). See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details. Note that the transformation to the decibel units is done by default using the standard acoustic reference pressure value of 2 x 10^{-5} Pa; you can change this value using the Acoustics Model Dialog Box (p. 2289).

SPL for Const Width Band *n* (dB)
(in the **Acoustics...** category) is the surface pressure level (in decibels) of the user-defined constant band *n*, as calculated by the Acoustic Sources FFT Dialog Box (p. 2549). See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details. Note that the transformation to the decibel units is done by default using the standard acoustic reference pressure value of 2 x 10^{-5} Pa; you can change this value using the Acoustics Model Dialog Box (p. 2289).

Static Pressure
(in the **Pressure...** category) is the static pressure of the fluid. It is a gauge pressure expressed relative to the prescribed operating pressure. The absolute pressure is the sum of the **Static Pressure** and the operating pressure. Its unit quantity is **pressure**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Static Temperature

(in the **Temperature...** and **Premixed Combustion...** categories) is the temperature in the fluid / solid. Its unit quantity is **temperature**. For a wall or shadow wall surface, the **Static Temperature** is the temperature of the adjacent fluid / solid cells; for a shell surface (see Postprocessing Shells (p. 843)), it is the temperature of the shell layer cells on the c0 side (that is, the side closer to the associated wall surface).

Note that **Static Temperature** will appear in the **Premixed Combustion...** category only for adiabatic premixed combustion calculations. See Postprocessing for Premixed Combustion Calculations (p. 1096).

Stored Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS Fluent, the partition ID can be used to determine the extent of the various groups of cells. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file. See Partitioning the Mesh Manually and Balancing the Load (p. 2033) for more information.

Strain Rate

(in the **Derivatives...** category) relates shear stress to the viscosity. Also called the shear rate ($\dot{\gamma}$ in Equation 7.35 (p. 492)), the strain rate is related to the second invariant of the rate-of-deformation tensor $\overline{\overline{D}}$. Its unit quantity is **time-inverse**. In 3D Cartesian coordinates, the strain rate, S, is defined as

$$\begin{aligned} S^2 = & \left[\frac{\partial u}{\partial x}\left(\frac{\partial u}{\partial x}+\frac{\partial u}{\partial x}\right)+\frac{\partial u}{\partial y}\left(\frac{\partial u}{\partial y}+\frac{\partial v}{\partial x}\right)+\frac{\partial u}{\partial z}\left(\frac{\partial u}{\partial z}+\frac{\partial w}{\partial x}\right)\right]+ \\ & \left[\frac{\partial v}{\partial x}\left(\frac{\partial v}{\partial x}+\frac{\partial u}{\partial y}\right)+\frac{\partial v}{\partial y}\left(\frac{\partial v}{\partial y}+\frac{\partial v}{\partial y}\right)+\frac{\partial v}{\partial z}\left(\frac{\partial v}{\partial z}+\frac{\partial w}{\partial y}\right)\right]+ \\ & \left[\frac{\partial w}{\partial x}\left(\frac{\partial w}{\partial x}+\frac{\partial u}{\partial z}\right)+\frac{\partial w}{\partial y}\left(\frac{\partial w}{\partial y}+\frac{\partial v}{\partial z}\right)+\frac{\partial w}{\partial z}\left(\frac{\partial w}{\partial z}+\frac{\partial w}{\partial z}\right)\right] \end{aligned} \tag{33.36}$$

For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Stream Function

(in the **Velocity...** category) is formulated as a relation between the streamlines and the statement of conservation of mass. A streamline is a line that is tangent to the velocity vector of the flowing fluid. For a 2D planar flow, the stream function, ψ, is defined such that

$$\rho u \equiv \frac{\partial \psi}{\partial y} \rho v \equiv -\frac{\partial \psi}{\partial x} \tag{33.37}$$

constant values of stream function defining two streamlines is the mass rate of flow between the streamlines.

The accuracy of the stream function calculation is determined by the text command `/display/set/n-stream-func`.

Stretch Factor

(in the **Premixed Combustion...** category) is a nondimensional parameter that is defined as the probability of unquenched flamelets (G in Equation 9.15 in the Theory Guide).

Subcritical Condition

(in the **Properties...** category) has a value of 1 if the flow condition is subcritical and 0 if the flow condition is supercritical and is available with the Cubic Equation of State Real Gas models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Subgrid Dissipation Rate

(in the **Turbulence...** category) is the turbulence dissipation rate of the unresolved eddies, eps_{sgs}, only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$eps_{sgs}=C_{eps}\cdot\frac{k_{sgs}^{3/2}}{L_s} \tag{33.38}$$

Its unit quantity is **turbulent-energy-diss-rate**.

Subgrid Dynamic Prandtl Number

(in the **Turbulence...** category) is used in the calculation of the subgrid-scale turbulent flux of a scalar φ, see Subgrid-Scale Models in the Theory Guide, Equation 4.282.

Subgrid Dynamic Sc of Species

(in the **Turbulence...** category) is used in the calculation of the subgrid-scale turbulent flux for Species (see Subgrid Dynamic Prandtl Number).

Subgrid Dynamic Viscosity Const

(in the **Turbulence...** category) is the Smagorinsky model constant as determined by the dynamic procedure described in Dynamic Smagorinsky-Lilly Model in the Theory Guide). Additional information with respect to the Embedded LES (E-LES) model can be found in Postprocessing for Turbulent Flows (p. 814).

Subgrid Filter Length

(in the **Turbulence...** category) is a mixing length for subgrid scales of the LES turbulence model (defined as L_S in Equation 4.285 in the Theory Guide).

Subgrid Kinetic Energy

(in the **Turbulence...** category) is the turbulence kinetic energy per unit mass of the unresolved eddies, k_{sgs}, calculated using a transport equation, only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$k_{sgs}=\frac{1}{2}\left(\overline{u_k^2}-\overline{u}_k^2\right) \tag{33.39}$$

Additional information with respect to the Embedded LES (E-LES) model can be found in Postprocessing for Turbulent Flows (p. 814). Its unit quantity is **turbulent-kinetic-energy**.

Subgrid Test–Filter Length

(in the **Turbulence...** category) is the test filter width $\hat{\Delta}$ described in Dynamic Smagorinsky-Lilly Model in the Theory Guide). Additional information with respect to the Embedded LES (E-LES) model can be found in Postprocessing for Turbulent Flows (p. 814).

Subgrid Turbulent Viscosity

(in the **Turbulence...** category) is the turbulent (dynamic) viscosity of the fluid calculated using the LES turbulence model. It expresses the proportionality between the anisotropic part of the subgrid-scale stress tensor and the rate-of-strain tensor. (See Equation 4.276 in the Theory Guide .) Its unit quantity is **viscosity**.

Subgrid Turbulent Viscosity Ratio

(in the **Turbulence...** category) is the ratio of the subgrid turbulent viscosity of the fluid to the laminar viscosity, calculated using the LES turbulence model.

Subtest Kinetic Energy

(in the **Turbulence...** category) is the turbulence kinetic energy of filtered eddies, kf, only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$k_f=L_1+L_2+L_3 \tag{33.40}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

with L_i being the normal components of the Leonard stress.

Its unit quantity is **turbulent-kinetic-energy**

Surface Acoustic Power
(in the **Acoustics...** category) is the **Acoustic Power** per unit area generated by boundary layer turbulence (see Equation 15.32 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used. Its unit quantity is **power** per **area**.

Surface Acoustic Power Level (dB)
(in the **Acoustics...** category) is the **Acoustic Power** per unit area generated by boundary layer turbulence, and represented in dB (see Equation 15.32 in the Theory Guide). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Surface Cluster ID
(in the **Radiation...** category) is used to view the distribution of surface clusters in the domain. Each cluster has a unique integer number (ID) associated with it.

Surface Corrosion Rate of species-n
(in the **Species...** category) is the rate of n^{th} solid species consumption/deposition. A positive value indicates corrosion of the solid species on the interface, and a negative value indicates deposition of the solid species.

Surface Coverage of species-n
(in the **Species...** category) is the amount of a surface species that is deposited on the substrate at a specific point in time.

Surface Deposition Rate of species-n
(in the **Species...** category) is the amount of a surface species that is deposited on the substrate. Its unit quantity is **mass-flux**.

Surface dpdt RMS, definition
(in the **Acoustics...** category) is the RMS value of the time-derivative of static pressure ($\partial p / \partial t$). It is available when the **Ffowcs-Williams & Hawkings** acoustics model is being used.

Surface Heat Transfer Coef.
(in the **Wall Fluxes...** category), as defined in ANSYS Fluent, is given by the equation

$$h_{eff} = \frac{q}{T_{wall} - T_{ref}} \tag{33.41}$$

T_{ref} is the reference temperature defined in the Reference Values Task Page (p. 2502). Note that T_{ref} is a constant value that should be representative of the problem. Its unit quantity is the **heat-transfer- coefficient**.

Surface Incident Radiation
(in the **Wall Fluxes...** category) is the net incoming radiation heat flux on a surface. Its unit quantity is **heat-flux**.

Surface Nusselt Number
(in the **Wall Fluxes...** category) is a local nondimensional coefficient of heat transfer defined by the equation

$$Nu = \frac{h_{eff} L_{ref}}{k} \tag{33.42}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surface Stanton Number

(in the **Wall Fluxes...** category) is a nondimensional coefficient of heat transfer defined by the equation

$$St = \frac{h_{eff}}{\rho_{ref} v_{ref} c_p} \tag{33.43}$$

v_{ref} are reference values of density and velocity defined in the Reference Values Task Page (p. 2502), and c_p is the specific heat at constant pressure.

Swirl Pull Velocity

(in the **Solidification/Melting...** category) is the tangential-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Swirl Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity in an axisymmetric swirling flow. See Velocity Reporting Options (p. 1933) for details. The unit quantity for **Swirl Velocity** is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Swirl-Wall Shear Stress

(in the **Wall Fluxes...** category) is the swirl component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Tangential Velocity

(in the **Velocity...** category) is the velocity component in the tangential direction. (See Velocity Reporting Options (p. 1933) for details.) The unit quantity for **Tangential Velocity** is **velocity**.

Temperature...

indicates the quantities associated with the thermodynamic temperature of a material.

Thermal Conductivity

(in the **Properties...** category) is a parameter (k) that defines the conduction rate through a material via Fourier's law ($q = -k\nabla T$). A large thermal conductivity is associated with a good heat conductor and a small thermal conductivity with a poor heat conductor (good insulator). Its unit quantity is **thermal-conductivity**. Note that when postprocessing solid material properties, the Thermal Conductivity will be displayed as zero if an anisotropic thermal conductivity model is being used for a solid material.

Thermal Diff Coef of species-n

(in the **Species...** category) is the thermal diffusion coefficient for the n^{th} species ($D_{T,i}$ in Equation 7.68 (p. 519), Equation 7.70 (p. 520), and Equation 7.74 (p. 521)). Its unit quantity is **viscosity**.

Time Step

(in the **Residuals...** category) is the local time step of the cell, Δt, at the current iteration level. Its unit quantity is **time**.

Time Step Scale

(in the **Species...** category) is the factor by which the time step is reduced for the stiff chemistry solver (available in the density-based solver only). The time step is scaled down based on an eigenvalue and positivity analysis.

Total Echem Heat Source

(in the **Potential...** category) is the summation of the Joule and Faradaic heat sources. The total heat source due to electrochemical chemical reactions is added to the energy equation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Total Energy

(in the **Temperature...** category) is the total energy per unit mass. Its unit quantity is **specific-energy**. For all species models, plots of **Total Energy** include the sensible, chemical and kinetic energies. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Enthalpy

(in the **Temperature...** category) is defined as $H+\frac{1}{2}v^2$ where H is the **Enthalpy**, as defined in Equation 5.7 in the Theory Guide , and v is the velocity magnitude. Its unit quantity is **specific-energy**. For all species models, plots of **Total Enthalpy** consist of the sensible, chemical and kinetic energies. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Enthalpy Deviation

(in the **Temperature...** category) is the difference between **Total Enthalpy** and the reference enthalpy, $H+\frac{1}{2}v^2-H_{ref}$, where H_{ref} is the reference enthalpy defined in the Reference Values Task Page (p. 2502). However, for non-premixed and partially premixed models, **Total Enthalpy Deviation** is the difference between **Total Enthalpy** and total adiabatic enthalpy (total enthalpy where no heat loss or gain occurs). The unit quantity for **Total Enthalpy Deviation** is **specific-energy**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Pressure

(in the **Pressure...** category) is the pressure at the thermodynamic state that would exist if the fluid were brought to zero velocity and zero potential. For compressible flows, the total pressure is computed using isentropic relationships. For constant c_p, this reduces to:

$$p_0=p\left[1+\frac{\gamma-1}{2}M^2\right]^{\gamma/(\gamma-1)} \tag{33.44}$$

For incompressible flows (constant density fluid), we use Bernoulli's equation, $p_0=p+p_{dyn}$, where p_{dyn} is the local dynamic pressure. Its unit quantity is **pressure**.

Important

Note that in the postprocessing, the total pressure is presented as gauge pressure, for compressible and incompressible flows. If the total absolute pressure is needed, then add the value of the reference pressure to the total gauge pressure.

Total Surface Corrosion Rate

(in the **Potential...** category) is the total rate of solid species consumption/deposition. A positive value indicates corrosion of the solid species on the interface, and a negative value indicates deposition of the solid species. It's computed as the sum of the surface corrosion rates (**Surface Corrosion Rates of species-n** reported under the **Species** category) of all species.

Total Surface Heat Flux

(in the **Wall Fluxes...** category) is the rate of total heat transfer through the control surface. It is calculated by the solver according to the boundary conditions being applied at that surface. By definition, heat flux out of the domain is negative, and heat flux into the domain is positive. The unit quantity for **Total Surface Heat Flux** is **heat-flux**.

Total Temperature

(in the **Temperature...** category) is the temperature at the thermodynamic state that would exist if the fluid were brought to zero velocity. For compressible flows, the total temperature is computed from the total enthalpy using the current c_p method (specified in the Create/Edit Materials Dialog Box (p. 2302)). For

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

incompressible flows, the total temperature is equal to the static temperature, unless kinetic energy is explicitly added. The unit quantity for **Total Temperature** is **temperature**.

Transmitted Radiation Flux (Band-n)

(in the **Wall Fluxes...** category) is the amount of radiative heat flux transmitted by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Transmitted Visible Solar Flux, Transmitted IR Solar Flux

(in the **Wall Fluxes...** category) is the amount of solar heat flux transmitted by a semi-transparent wall or porous jump boundary for a visible or infrared radiation.

Turbulence...

includes quantities related to turbulence. See Modeling Turbulence (p. 749) for information about the turbulence models available in ANSYS Fluent.

Turbulence Intensity

(in the **Turbulence...** category) is the ratio of the magnitude of the RMS turbulent fluctuations to the reference velocity:

$$I=\frac{\sqrt{\frac{2}{3}k}}{v_{ref}} \tag{33.45}$$

where k is the turbulence kinetic energy and v_{ref} is the reference velocity specified in the Reference Values Task Page (p. 2502). The reference value specified should be the mean velocity magnitude for the flow. Note that turbulence intensity can be defined in different ways, so you may want to use a custom field function for its definition. See Custom Field Functions (p. 2003) for more information.

Turbulent Dissipation Rate (Epsilon)

(in the **Turbulence...** category) is the turbulent dissipation rate. Its unit quantity is **turbulent-energy-diss-rate**. This quantity is available for the k-epsilon and k-omega based turbulence models, where the epsilon/omega relationship is defined as

$$\varepsilon=0.09k\omega \tag{33.46}$$

For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Turbulent Flame Speed

(in the **Premixed Combustion...** category) is the turbulent flame speed computed by ANSYS Fluent using Equation 9.9 in the Theory Guide . Its unit quantity is **velocity**.

Turbulent Kinetic Energy (k)

(in the **Turbulence...** category) is the turbulence kinetic energy per unit mass defined as

$$k=\frac{1}{2}\overline{u_i'u_i'} \tag{33.47}$$

Turbulent Rate of Reaction-n

(in the **Reactions...** category) is the rate of progress of the n^{th} reaction computed by Equation 7.25 or Equation 7.26 (in the Theory Guide). For the "eddy-dissipation" model, the value is the same as the **Rate of Reaction-n**. For the "finite-rate" model, the value is zero.

Turbulent Reynolds Number (Re_y)

(in the **Turbulence...** category) is a nondimensional quantity defined as

$$\frac{\rho d\sqrt{k}}{\mu_{lam}} \tag{33.48}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where k is turbulence kinetic energy, d is the distance to the nearest wall, and μ_{lam} is the laminar viscosity.

Turbulent Viscosity
(in the **Turbulence...** category) is the turbulent viscosity of the fluid computed using the turbulence model. Its unit quantity is **viscosity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. Additional information with respect to the Embedded LES (E-LES) model can be found in Postprocessing for Turbulent Flows (p. 814).

Turbulent Viscosity (large-scale)
(in the **Turbulence...** category) is used in the k-kl-ω transition model.See Transport Equations for the k-kl-ω Model in the Theory Guide for more details (Equation 4.149).

Turbulent Viscosity (small-scale)
(in the **Turbulence...** category) is used in the k-kl-ω transition model.See Transport Equations for the k-kl-ω Model in the Theory Guide for more details (Equation 4.143).

Turbulent Viscosity Ratio
(in the **Turbulence...** category) is the ratio of turbulent viscosity to the laminar viscosity. Additional information with respect to the Embedded LES (E-LES) model can be found in Postprocessing for Turbulent Flows (p. 814).

udm-n
(in the **User Defined Memory...** category) is the value of the quantity in the n^{th} user-defined memory location.

Unburnt Fuel Mass Fraction
(in the **Premixed Combustion...** category) is the mass fraction of unburnt fuel. This function is available only for non-adiabatic models.

Unsteady Statistics...
includes mean and root mean square error (RMSE) values of solution variables and custom field functions derived from transient flow calculations.

User Defined Memory...
includes quantities that have been allocated to a user-defined memory location. See the separate Fluent Customization Manual for details about user-defined memory.

User-Defined Scalars...
includes quantities related to user-defined scalars. See the separate Fluent Customization Manual for information about using user-defined scalars.

UU Reynolds Stress
(in the **Turbulence...** category) is the $\overline{u'^2}$ stress.

UV Reynolds Stress
(in the **Turbulence...** category) is the $\overline{u'v'}$ stress.

UW Reynolds Stress
(in the **Turbulence...** category) is the $\overline{u'w'}$ stress.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Variance of Species

(in the **NOx...** category) is the variance of the mass fraction of a selected species in the flow field. It is calculated from Equation 14.113 in the Theory Guide .

Variance of Species 1, Variance of Species 2

(in the **NOx...** category) are the variances of the mass fractions of the selected species in the flow field. They are each calculated from Equation 14.113 in the Theory Guide .

Variance of Temperature

(in the **NOx...** category) is the variance of the normalized temperature in the flow field. It is calculated from Equation 14.113 in the Theory Guide.

Velocity...

includes the quantities associated with the rate of change in position with time. The instantaneous velocity of a particle is defined as the first derivative of the position vector with respect to time, $d\vec{r} / dt$, termed the velocity vector, $\vec{v}$.

Velocity Angle

(in the **Velocity...** category) is defined as follows:

For a 2D model,

$$\tan^{-1}\left(\frac{\text{y-velocity-component}}{\text{x-velocity-component}}\right) \tag{33.49}$$

For a 2D or axisymmetric model,

$$\tan^{-1}\left(\frac{\text{radial-velocity-component}}{\text{axial-velocity-component}}\right) \tag{33.50}$$

For a 3D model,

$$\tan^{-1}\left(\frac{\text{tangential-velocity-component}}{\text{axial-velocity-component}}\right) \tag{33.51}$$

Its unit quantity is **angle**.

Velocity Magnitude

(in the **Velocity...** category) is the speed of the fluid. Its unit quantity is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Volume fraction

(in the **Phases...** category) is the volume fraction of the selected phase in the **Phase** drop-down list.

Volumetric Absorbed Radiation

(in the **Radiation...** category) is the spherical mean absorbed radiation and, for a single spectral band, can be defined as:

$$4\pi I\alpha \tag{33.52}$$

where I is the radiation intensity and α is the absorption coefficient.

Volumetric Emitted Radiation

(in the **Radiation...** category) is the spherical mean emitted radiation and, for a single spectral band, can be defined as.

$$4\varepsilon\sigma T^4\alpha \tag{33.53}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where ε is the blackbody fraction, σ is the Stefan-Boltzmann constant, T is the temperature, and α is the absorption coefficient.

Vorticity Magnitude

(in the **Velocity...** category) is the magnitude of the vorticity vector. Vorticity is a measure of the rotation of a fluid element as it moves in the flow field, and is defined as the curl of the velocity vector:

$$\xi = \nabla \times \vec{V} \tag{33.54}$$

VV Reynolds Stress

(in the **Turbulence...** category) is the $\overline{v'^2}$ stress.

VW Reynolds Stress

(in the **Turbulence...** category) is the $\overline{v'w'}$ stress.

Wall Film Face Pressure

(in the **Wall Film…** category) is the face pressure of the wall film.

Wall Film Height

(in the **Wall Film…** category) is the height of the wall film.

Wall Film Heat Flux

(in the **Wall Film…** category) is the heat flux of the wall film to the wall.

Wall Film Impingement Mass Flux

(in the **Wall Film…** category) is the mass flux impinging on the wall film.

Wall Film Mass

(in the **Wall Film…** category) is the mass of the wall film (in units of mass).

Wall Film Temperature

(in the **Wall Film…** category) is the temperature of the wall film.

Wall Film Velocity Magnitude

(in the **Wall Film…** category) is the velocity magnitude of the wall film.

Wall Film X-Velocity

(in the **Wall Film…** category) is the x-component of the velocity of the wall film.

Wall Film Y-Velocity

(in the **Wall Film…** category) is the y-component of the velocity of the wall film.

Wall Film Z-Velocity

(in the **Wall Film…** category) is the z-component of the velocity of the wall film.

Wall Fluxes...

includes quantities related to forces and heat transfer at wall surfaces.

Wall Func. Heat Tran. Coef.

is generally defined by the equation

$$h_{eff} = \frac{\rho c_p u^*}{T_c^*} - \frac{D / \left(T_w - T_p \right)}{T_c^*} \tag{33.55}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where c_p is the specific heat, u^* is the near-wall turbulence velocity scale, D is the viscous heating (included only for variable density flows, Equation 4.321 in the *Fluent Theory Guide*), T_c^* is the dimensionless law-of-the-wall temperature defined for the standard wall functions in Equation 4.320 in the *Fluent Theory Guide*. For the enhanced wall treatment, the combined forms for D and T_c^* (Equation 4.320 and Equation 4.321 in the *Fluent Theory Guide*) are replaced by the corresponding functions obtained using the blending of Kader, explained in Enhanced Wall Treatment for Momentum and Energy Equations in the *Fluent Theory Guide*.

Wall Irradiation Flux.Normalized Std Deviation

(in the **Radiation...** category) is the statistical standard deviation for the hemispherical mean irradiation flux.

Wall Shear Stress

(in the **Wall Fluxes...** category) is the force acting tangential to the surface due to friction. Its unit quantity is **pressure**. For multiphase models, this value corresponds Equation 4.321 in the *Fluent Theory Guide* to the selected phase in the **Phase** drop-down list.

Wall Temperature

(in the **Temperature...** category) is the temperature on a surface (including wall surfaces, shadow wall surfaces, and shell surfaces). For an illustration of such surfaces for thin walls and shells, see Figure 6.43: A Thin Wall (p. 374) and Figure 12.5: A Boundary Wall with Shell Conduction (p. 839), respectively.

Wall Temperature (Thin)

(in the **Temperature...** category) is for thin walls only, and reports the temperature on the surface that is separated from the fluid / solid cells by the wall thickness, as shown in Figure 6.43: A Thin Wall (p. 374). Note that the wall thermal boundary conditions are applied on this surface.

Wall Yplus

(in the **Turbulence...** category) is a nondimensional parameter defined by the equation

$$y^+ = \frac{\rho u_\tau y_P}{\mu} \tag{33.56}$$

where $u_\tau = \sqrt{\tau_w / \rho_w}$ is the friction velocity, y_P is the distance from point P to the wall, ρ is the fluid density, and μ is the fluid viscosity at point P. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide for details. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Wall Ystar

(in the **Turbulence...** category) is a nondimensional parameter defined by the equation

$$y^* = \frac{\rho C_\mu^{1/4} k_P^{1/2} y_P}{\mu} \tag{33.57}$$

where k_P is the turbulence kinetic energy at point P, y_P is the distance from point P to the wall, ρ is the fluid density, and μ is the fluid viscosity at point P. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide for details.

WW Reynolds Stress

(in the **Turbulence...** category) is the $\overline{w'^2}$ stress.

X-Coordinate, Y-Coordinate, Z-Coordinate

(in the **Mesh...** category) are the Cartesian coordinates in the x-axis, y-axis, and z-axis directions respectively. The unit quantity for these variables is **length**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

X Face Area, Y Face Area, Z Face Area
(in the **Mesh...** category) are the components of the face area vector for noninternal faces (that is, faces that only have `c0` and no `c1`). The values are stored on the face itself and used when required. These variables are intended only for zone surfaces and not for other surfaces created for postprocessing.

X Pull Velocity, Y Pull Velocity, Z Pull Velocity
(in the **Solidification/Melting...** category) are the x, y, and z components of the pull velocity for the solid material in a continuous casting process. The unit quantity for each is **velocity**.

X Velocity, Y Velocity, Z Velocity
(in the **Velocity...** category) are the components of the velocity vector in the x-axis, y-axis, and z-axis directions, respectively. The unit quantity for these variables is **velocity**. For multiphase models, these values correspond to the selected phase in the **Phase** drop-down list.

X-Vorticity, Y-Vorticity, Z-Vorticity
(in the **Velocity...** category) are the x, y, and z components of the vorticity vector.

X-Wall Shear Stress, Y-Wall Shear Stress, Z-Wall Shear Stress
(in the **Wall Fluxes...** category) are the x, y, and z components of the force acting tangential to the surface due to friction. The unit quantity for these variables is **pressure**. For multiphase models, these values correspond to the selected phase in the **Phase** drop-down list.

33.5. Custom Field Functions

In addition to the basic field variables provided by ANSYS Fluent (and described in Alphabetical Listing of Field Variables and Their Definitions (p. 1957)), you can also define your own field functions to be used in conjunction with any of the commands that use these variables (contour and vector display, XY plots, and so on). This capability is available with the Custom Field Function Calculator Dialog Box (p. 2683). You can use the default field variables, previously defined calculator functions, and calculator operators to create new functions. (Several sample functions are described in Sample Custom Field Functions (p. 2007).)

Any field functions that you define will be saved in the case file the next time that you save it. You can also save your custom field functions to a separate file (as described in Manipulating, Saving, and Loading Custom Field Functions (p. 2006)), so that they can be used with a different case file.

Important

Note that all custom field functions are evaluated and stored in SI units.

Any solver-defined flow variables that you use in your field-function definition will be automatically converted if they are not already in SI units, but you must be careful to enter constants in the appropriate units. Note also that explicit node values are not available for custom field functions; all node values for these functions will be computed by averaging the values in the surrounding cells, as described in Node Values (p. 1931).

For additional information, see the following sections:

33.5.1. Creating a Custom Field Function
33.5.2. Manipulating, Saving, and Loading Custom Field Functions
33.5.3. Sample Custom Field Functions

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

33.5.1. Creating a Custom Field Function

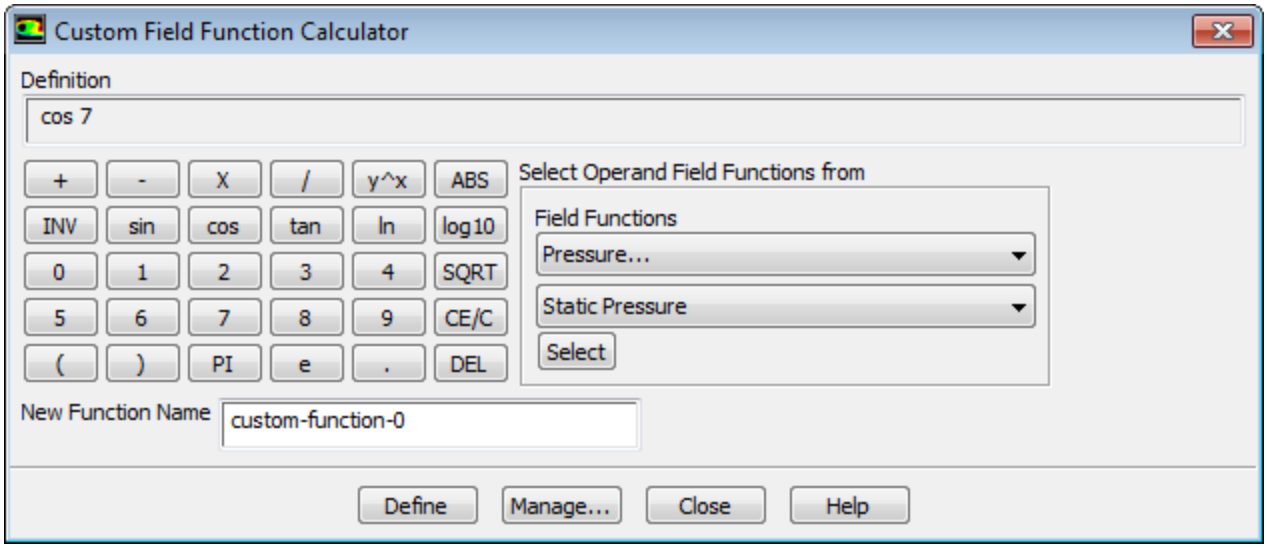
To create your own field function, you will use the Custom Field Function Calculator Dialog Box (p. 2683) (Figure 33.3: The Custom Field Function Calculator Dialog Box (p. 2004)). This dialog box allows you to define field functions based on existing functions, using simple calculator operators. Any functions that you define will be added to the list of default flow variables and other field functions provided by the solver.

Parameters & Customization → Custom Field Functions New...

Important

Recall that you must enter all constants in the function definition in SI units.

Figure 33.3: The Custom Field Function Calculator Dialog Box



The steps for creating a custom field function are as follows:

1. Use the calculator buttons and the **Field Functions** list and **Select** button to specify the function definition, as described below. (As you select each item from the **Field Functions** list or click a button in the calculator keypad, its symbol will appear in the **Definition** text entry box. You *cannot* edit the contents of this box directly; if you want to delete part of a function, use the **DEL** button on the keypad.)

   Important

   The range of integers and real numbers that can be stored is as follows:

   $-2147483648 > integers < 2147483647$

   $-1.79769e{+}308 > real < 1.79769e{+}308$

   Note that using a number less than 1e-39 may produce inaccurate results, while values less than 1e-45 will produce a result of zero.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Specify the name of the function in the **New Function Name** field.

> **Important**
>
> Be sure that you do not specify a name that is already used for a standard field function (for example, `velocity-magnitude`); you can see a complete list of the predefined field functions in ANSYS Fluent by selecting the `display/contours` text command and viewing the available choices for `contours of`.

3. Click the **Define** button.

When you click **Define**, the solver will create the function and add it to the list of **Custom Field Functions** within the drop-down list of available field functions. The **Define** push button is grayed out after you create a new function or if the **Definition** text entry box is empty.

Should you decide to rename or delete the function after you have completed the definition, you can do so in the Field Function Definitions Dialog Box (p. 2704), which you can open by clicking on the **Manage...** push button. See Manipulating, Saving, and Loading Custom Field Functions (p. 2006) for details.

33.5.1.1. Using the Calculator Buttons

Your function definition can include many basic calculator operations (for example, addition, subtraction, multiplication, square root). When you select a calculator button (by clicking on it), the appropriate symbol will appear in the **Definition** text entry box. The meaning of the buttons is straightforward; they are similar to the buttons you would find on any standard calculator. You should, however, note the following:

- The **CE/C** button will clear the entire **Definition** and the **New Function Name**, if you have entered one. The **DEL** button will delete only the last entry in the **Definition** text entry box. You can use **DEL** to delete characters one at a time, starting with the last one entered.
- To obtain the inverse trigonometric functions arcsin, arccos, and arctan, click the **INV** button before selecting **sin**, **cos**, or **tan**.
- The **ABS** button yields the absolute value of the number that follows it. Likewise, the **ln** button yields the natural logarithm of the number that follows it, and the **log10** button yields the base 10 logarithm function of the number that follows it.

> **Important**
>
> **log10** and **ln** will be calculated for values greater than 0. For values less than or equal to 0, the resultant value will be zero.

- The **PI** button represents π and the **e** button represents the base of the natural logarithm system (which is approximately equal to 2.71828).

33.5.1.2. Using the Field Functions List

Your function definition can include any of the field functions defined by the solver (and listed in Alphabetical Listing of Field Variables and Their Definitions (p. 1957)) or by you. You can also use any report

definitions that you have created (see Monitoring and Reporting Solution Data (p. 1885) for additional information). To include one of these variables/functions in your function definition, select it in the **Field Functions** drop-down list and then click the **Select** button below the list. The symbol for the selected item will appear in the **Definition** text entry box (for example, **p** will appear if you select **Static Pressure**).

Note

If a custom field function definition uses a report definition, then it cannot be exported to a file.

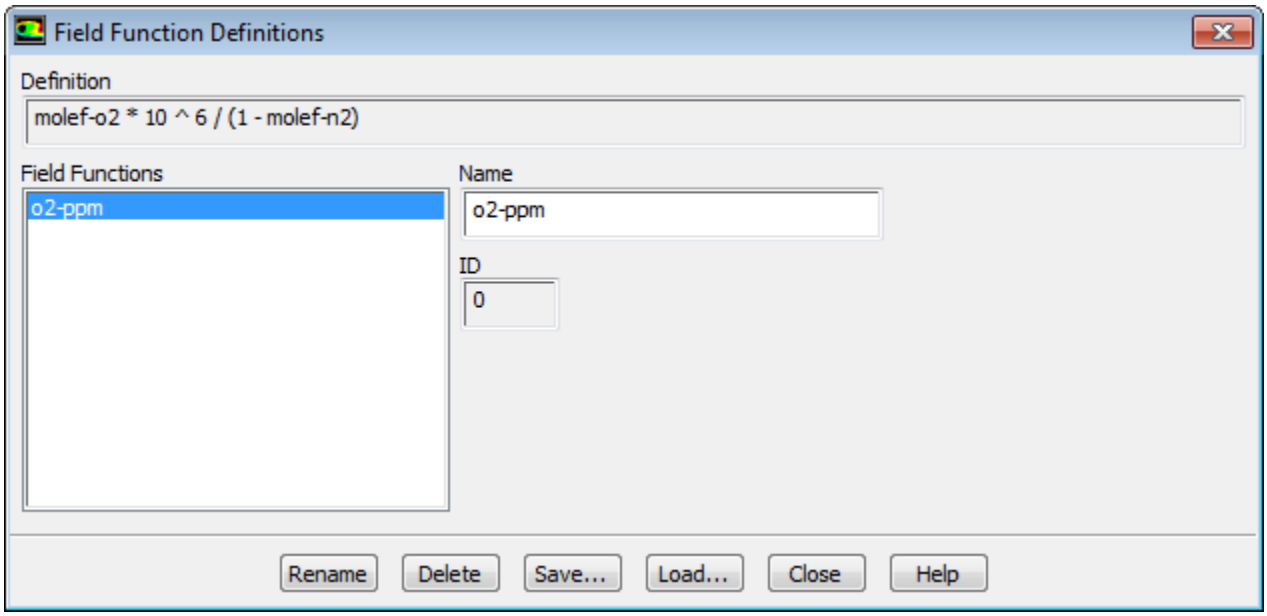
33.5.2. Manipulating, Saving, and Loading Custom Field Functions

Once you have defined your field functions, you can manipulate them using the Field Function Definitions Dialog Box (p. 2704) (Figure 33.4: The Field Function Definitions Dialog Box (p. 2006)). You can display a function definition to be sure that it is correct, delete the function if you decide that it is incorrect and must be redefined, or give the function a new name. You can also save custom field functions to a file or read them from a file. The custom field function file allows you to transfer your custom functions between case files.

To open the Field Function Definitions Dialog Box (p. 2704), right-click **Custom Field Functions** (under the **Parameters & Customization** branch of the tree) and select **Manage...**. You can also click the **Manage...** button in the Custom Field Function Calculator Dialog Box (p. 2683).

To open the Field Function Definitions Dialog Box (p. 2704), right-click **Custom Field Functions** (under the **Parameters & Customization** branch of the tree) and select **Manage...**. You can also click the **Manage...** button in the Custom Field Function Calculator Dialog Box (p. 2683).

Figure 33.4: The Field Function Definitions Dialog Box



The following actions can be performed in the Field Function Definitions Dialog Box (p. 2704):

- To check the definition of a function, select it in the **Field Functions** list. Its definition will be displayed in the **Definition** field. This display is for informational purposes only; you cannot edit it. If you want to change

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a function definition, you must delete the function and define it again in the Custom Field Function Calculator Dialog Box (p. 2683).

- To delete a function, select it in the **Field Functions** list and click the **Delete** button.
- To rename a function, select it in the **Field Functions** list, enter a new name in the **Name** field, and click the **Rename** button.

Important

Be sure that you do not specify a name that is already used for a standard field function (for example, `velocity-magnitude`); you can see a complete list of the predefined field functions in ANSYS Fluent by selecting the `display/contours` text command and viewing the available choices for `contours of`.

- To save all of the functions in the **Field Functions** list to a file, click the **Save...** button and specify the file name in The Select File Dialog Box (p. 19).
- To read custom field functions from a file that you saved as described above, click the **Load...** button and specify the file name in the resulting **Select File** dialog box. (Custom field function files are valid Scheme functions, and can also be loaded with the **File/Read/Scheme...** ribbon tab item, as described in Reading Scheme Source Files (p. 57).)

33.5.3. Sample Custom Field Functions

When you are checking the results of your simulation, you may find it useful to define some of the following field functions:

- To define a function that determines the ratio of static pressure to inlet total pressure, use the relationship

$$R=\frac{p+p_{op}}{p_{to}+p_{op}} \tag{33.58}$$

where p is the static pressure calculated by the solver, p_{to} is the inlet total pressure, and p_{op} is the operating pressure for the problem. Use the solver-defined function **Static Pressure** for p, and the numerical value that you specified for **Gauge Total Pressure** in the Pressure Inlet Dialog Box (p. 2434) for p_{to}. Specify the value of the operating pressure to be the value that you set in the Operating Conditions Dialog Box (p. 2382). As discussed in Operating Pressure (p. 530), all pressures in ANSYS Fluent are gauge pressures relative to the operating pressure. If the operating pressure is zero, as is generally the case for compressible flow calculations, the expression for the pressure ratio reduces to

$$PR=\frac{p}{p_{to}} \tag{33.59}$$

- To define a function that determines the critical velocity ratio v/a_*, a parameter that is sometimes used in turbomachinery calculations, use the relationship

$$\frac{v}{a_*}=\left[\left(\frac{\gamma+1}{\gamma-1}\right)\left(1-PR^{(\gamma-1)/\gamma}\right)\right]^{1/2} \tag{33.60}$$

In this relationship, a_* is the critical velocity (that is, the velocity that would occur for the same stagnation conditions if $M=1$), γ is the ratio of specific heats, and PR is the pressure ratio defined in

Equation 33.59 (p. 2007) for which you created your own function. For γ, ratio of specific heats, select **Specific Heat Ratio (gamma)** in the **Properties...** category. To include PR, select **Custom Field Functions...** in the first drop-down list under **Field Functions**, and then select from the second list the function name that you assigned PR.

- Suppose you have swirling flow in a pipe, aligned with the z axis, and you want to calculate the flow rate of angular momentum through a cross-sectional plane:

$$\int \rho r v_\theta \vec{v} \cdot d\vec{A} \tag{33.61}$$

You can create a function for the product rv_θ, where r is the **Radial Coordinate** and v_θ is the **Tangential Velocity**. Then use the Surface Integrals Dialog Box (p. 2616) to compute the flow rate of this quantity.

Important

The custom field function containing model dependent functions (like temperature when the energy equation is enabled) will be computed only when those models are still active.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 34: Parallel Processing

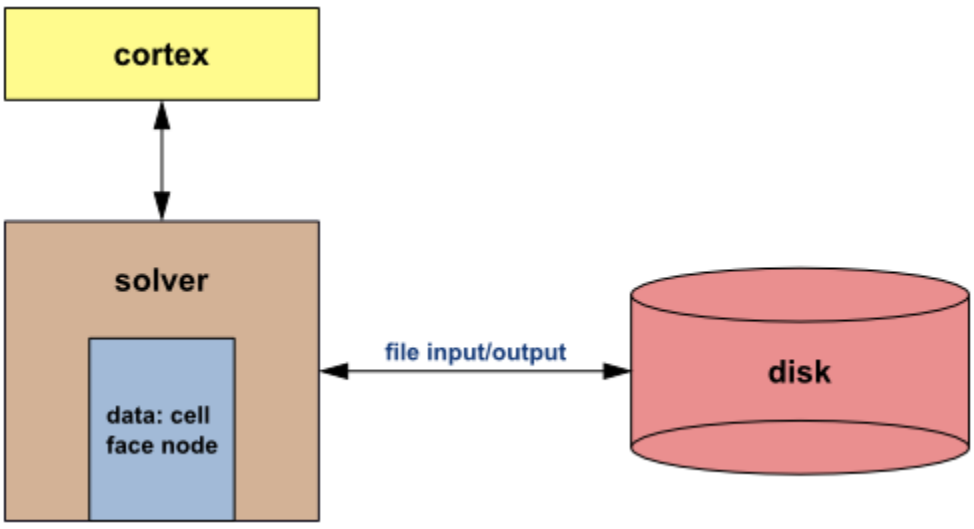
The following sections describe the parallel-processing features of ANSYS Fluent.

34.1. Introduction to Parallel Processing
34.2. Starting Parallel ANSYS Fluent Using Fluent Launcher
34.3. Starting Parallel ANSYS Fluent on a Windows System
34.4. Starting Parallel ANSYS Fluent on a Linux System
34.5. Mesh Partitioning and Load Balancing
34.6. Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver
34.7. Controlling the Threads
34.8. Checking Network Connectivity
34.9. Checking and Improving Parallel Performance

34.1. Introduction to Parallel Processing

The ANSYS Fluent serial solver manages file input and output, data storage, and flow field calculations using a single solver process on a single computer (Figure 34.1: Serial ANSYS Fluent Architecture (p. 2009)).

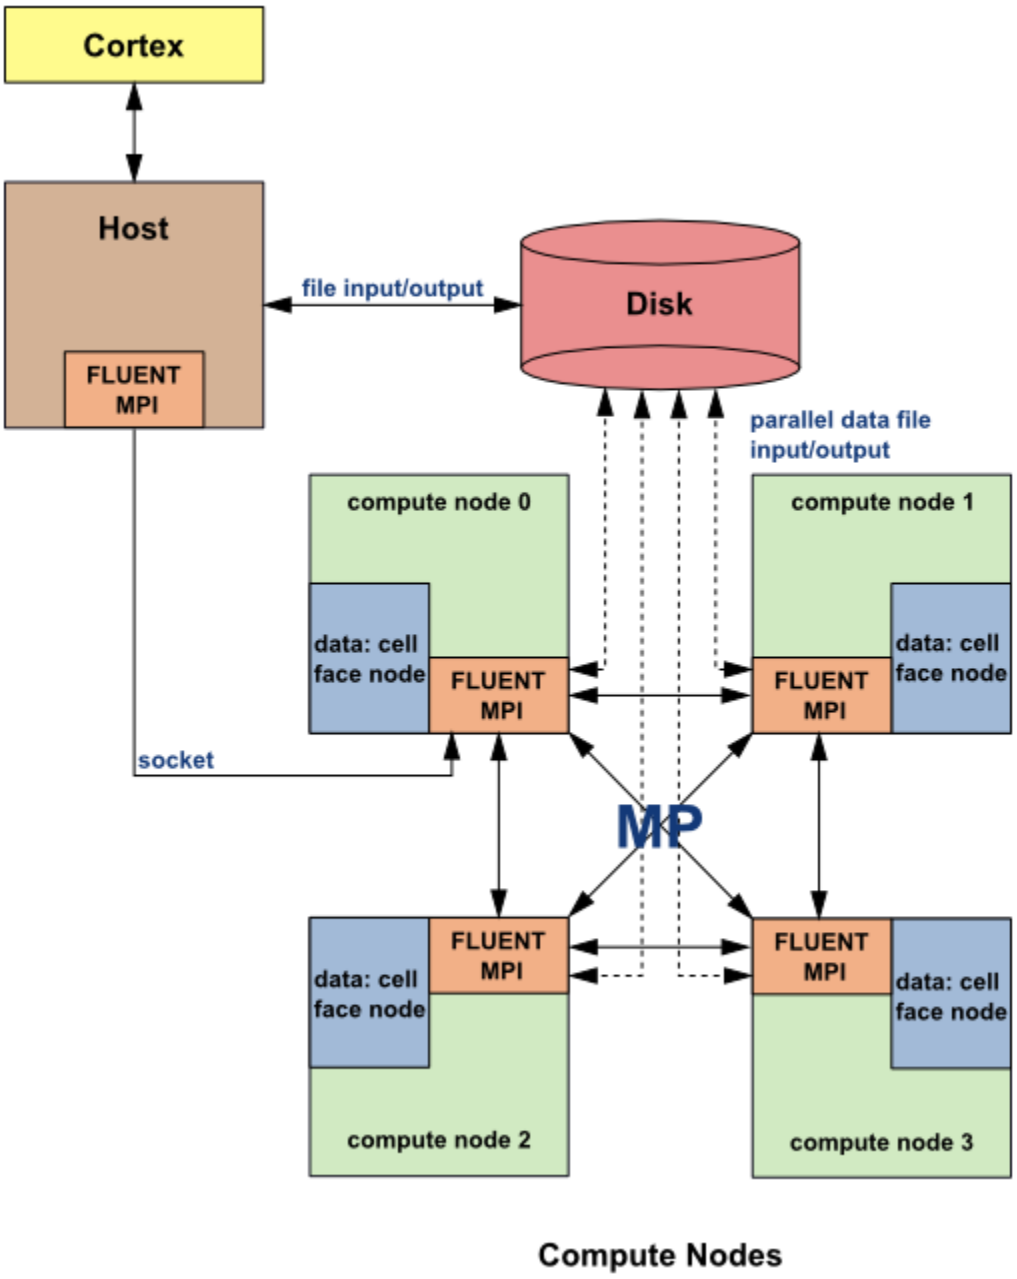
Figure 34.1: Serial ANSYS Fluent Architecture



ANSYS Fluent's parallel solver allows you to compute a solution by using multiple processes that may be executing on the same computer, or on different computers in a network (Figure 34.2: Parallel ANSYS Fluent Architecture (p. 2010)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.2: Parallel ANSYS Fluent Architecture



Parallel processing in ANSYS Fluent involves an interaction between ANSYS Fluent, a host process, and a set of compute-node processes. ANSYS Fluent interacts with the host process and the collection of compute nodes using a utility called `cortex` that manages ANSYS Fluent's user interface and basic graphical functions.

Parallel ANSYS Fluent splits up the mesh and data into multiple partitions, then assigns each mesh partition to a different compute process (or node). The number of partitions is equal to or less than the number of processors (or cores) available on your compute cluster. The compute-node processes can be executed on a massively-parallel computer, a multiple-CPU workstation, or a network cluster of computers.

Generally, as the number of compute nodes increases, turnaround time for solutions will decrease. This is referred to as solver "scalability." However, beyond a certain point, the ratio of network communication

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

to computation increases, leading to reduced parallel efficiency, so optimal system sizing is important for simulations.

ANSYS Fluent uses a host process that does not store any mesh or solution data. Instead, the host process only interprets commands from ANSYS Fluent's graphics-related interface, `cortex`.

The host distributes those commands to the other compute nodes via a socket interconnect to a single designated compute node called `compute-node-0`. This specialized compute node distributes the host commands to the other compute nodes. Each compute node simultaneously executes the same program on its own data set. Communication from the compute nodes to the host is possible only through `compute-node-0` and only when all compute nodes have synchronized with each other.

Each compute node is virtually connected to every other compute node, and relies on inter-process communication to perform such functions as sending and receiving arrays, synchronizing, and performing global operations (such as summations over all cells). Inter-process communication is managed by a message-passing library. For example, the message-passing library could be a vendor implementation of the Message Passing Interface (MPI) standard, as depicted in Figure 34.2: Parallel ANSYS Fluent Architecture (p. 2010).

All of the parallel ANSYS Fluent processes (as well as the serial process) are identified by a unique integer ID. The host collects messages from `compute-node-0` and performs operations (such as printing, displaying messages, and writing to a file) on all of the data, in the same way as the serial solver. You have the option of bypassing the host when inputting or outputting parallel data files, so that the data is passed directly between the compute nodes and the disk in a parallel fashion. This can reduce the time for data file I/O operations (for details, see Reading and Writing Parallel Data Files (p. 51)).

For additional information, see the following section:
34.1.1. Recommended Usage of Parallel ANSYS Fluent

34.1.1. Recommended Usage of Parallel ANSYS Fluent

The recommended procedure for using parallel ANSYS Fluent is as follows:

1. Start up the parallel solver. For details, see Starting Parallel ANSYS Fluent on a Windows System (p. 2021) and Starting Parallel ANSYS Fluent on a Linux System (p. 2026).

2. Read your case file and have ANSYS Fluent partition the mesh automatically upon loading it.

3. Review the partitions and perform partitioning again, if necessary. See Checking the Partitions (p. 2052) for details on checking your partitions. Note that there are other approaches for partitioning, including manual partitioning in either the serial or the parallel solver. For details, see Mesh Partitioning and Load Balancing (p. 2030).

4. Calculate a solution. See Checking and Improving Parallel Performance (p. 2060) for information on checking and improving the parallel performance.

Note

Due to limitations imposed by several MPI implementations, ANSYS Fluent performance on heterogeneous clusters involving either operating system or processor family differences may not be optimal, and in certain cases cause failures. You are urged to use caution in such parallel operating environments.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.2. Starting Parallel ANSYS Fluent Using Fluent Launcher

Whether you start ANSYS Fluent either from the Linux or Windows command line with no arguments, from the Windows Programs menu, or from the Windows desktop, Fluent Launcher will appear (for details, see Starting ANSYS Fluent Using Fluent Launcher in the Getting Started Guide), where you can specify the dimensionality of the problem (2D or 3D), as well as other options (for example, whether you want a single-precision or double-precision calculation).

Parallel calculation options can be set up by selecting **Parallel** under **Processing Options** in Fluent Launcher. Once you select the **Parallel** option, you can also specify the number of processes using the **Processes** field under **Solver**.

If your machines are equipped with appropriate General Purpose Graphical Processing Units (GPGPUs) you can indicate that these should be used for AMG solver acceleration by setting the **GPGPUs per Machine** option. Note that the number of solver processes per machine must be the same for all machines and that the number of processes per machine must be evenly divisible into the value you specify for **GPGPUs per Machine**. That is, for *nprocs* solver processes running on *M* machines using *ngpgpus* GPGPUS per machine:

$$nprocs \bmod M = 0$$
$$\left(\frac{nprocs}{M}\right) \bmod ngpgpus = 0$$

Table 34.1: Examples for GPGPUs per Machine (p. 2012) presents several examples illustrating the relationship between number of machines, number of solver processes, and GPGPUs per machine.

Table 34.1: Examples for GPGPUs per Machine

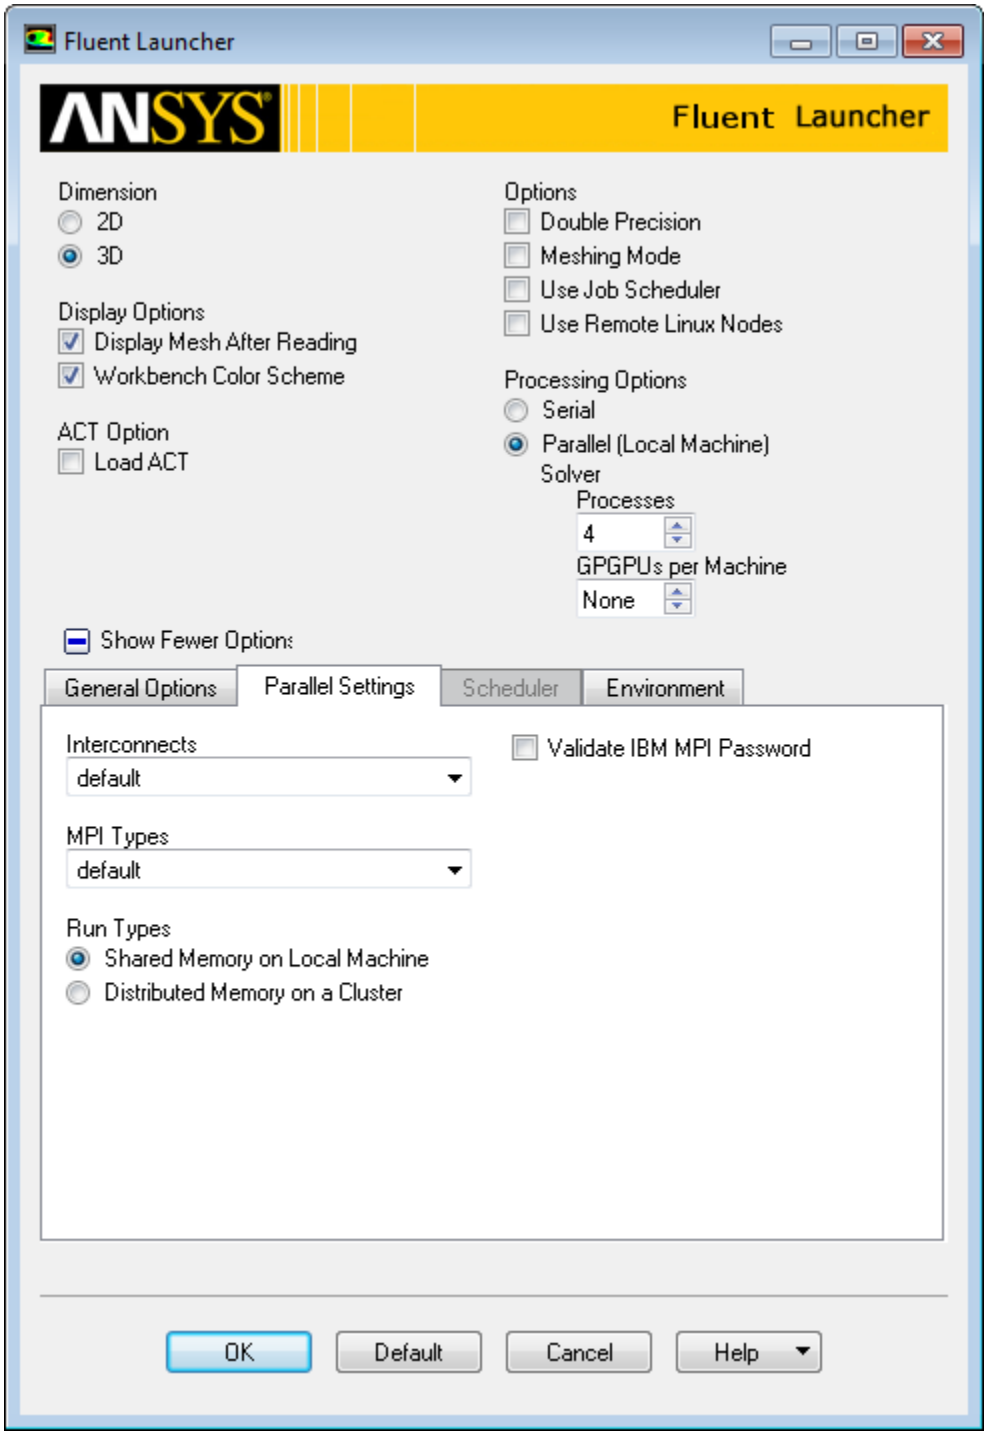
	Example 1	Example 2	Example 3
Number of Machines (`M`)	1	4	4
Number of Solver Processes (`nprocs`)	4	12	22
Valid values for GPGPUs per Machine (`ngpgpus`)	1, 2, 4	1, 3	`ngpgpus` will be ignored and GPGPU acceleration will be disabled (`M` does not evenly divide `nprocs`)

See Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver (p. 2056) for more information about using GPGPU acceleration.

Activating the **Parallel** option enables the **Parallel Settings** tab (visible when you select the **Show More Options** button). The **Parallel Settings** tab allows you to specify settings for running ANSYS Fluent in parallel.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.3: The Parallel Settings Tab of Fluent Launcher



- Specify the interconnect in the **Interconnects** drop-down list. The default setting is recommended. For a symmetric multi-processor (SMP) system, the default setting uses shared memory for communication. On Windows, the best available interconnect is automatically used.

  (Linux only) If you prefer to select a specific interconnect, you can choose either **ethernet**, **myrinet**, or **infiniband**. For more information about these interconnects, see Table 34.5: Supported Interconnects for Linux Platforms (Per Platform) (p. 2028), Table 34.6: Available MPIs for Linux Platforms (p. 2028), and Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect) (p. 2028).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Specify the type of message passing interface (MPI) you require for the parallel computations in the **MPI Types** field. The list of MPI types varies depending on the selected release and the selected architecture. There are several options, based on the operating system of the parallel cluster. For more information about the available MPI types, see Table 34.2: Supported Interconnects for the Windows Platform (p. 2023) - Table 34.3: Available MPIs for Windows Platforms (p. 2023).

  Important

  It is your responsibility to make sure the interconnects and the MPI types are compatible. If incompatible inputs are used, Fluent Launcher resorts to using the default values.

- (Linux Only) Specify either **RSH** (remote shell client) or **SSH** (secure shell client) under **Remote Spawn Command**. For more information about setting up your remote shell clients and secure shell clients, see Setting Up Your Remote Shell and Secure Shell Clients (p. 2029).

- Specify the type of parallel calculation under **Run Types**:

  – Select **Shared Memory on Local Machine** if the parallel calculations are performed by sharing memory allocations on your local machine.

  – Select **Distributed Memory on a Cluster** if the parallel calculations will be distributed among several machines.

    You can select **Machine Names** and enter the machine names directly into the text field as a list. Machine names can be separated either by a comma or a space. This is not recommended for a long list of machine names.

    Alternatively, you can select **File Containing Machine Names** to specify a hosts file (a file that contains the machine names), or you can use the button to browse for a hosts file.

    To edit an existing hosts file, click the button.

    By default, Fluent allocates ranks to machines in contiguous blocks, where the block sizes are as equal as possible. You can control the per machine block allocation size using the `machine` *X* `:` *Y* convention in the hosts specification, where *Y* is the process block count for `machine` *X*. The process assignment will cycle through the machine list until all processes are allocated in specified blocks. A fully round-robin assignment of processes can be achieved by setting the machine block allocation sizes to 1 (for example, `machine1:1`, `machine2:1`, and so on).

- Specify if you would like to validate the password for the IBM MPI or not.

  Select the **Validate IBM MPI Password** option if you would like to save the required password to use the IBM MPI type.

- For certain platforms, select **Use Job Scheduler** under **Options** if the parallel calculations are to be performed using a designated Job Scheduler (for details, see Setting Parallel Scheduler Options in Fluent Launcher (p. 2015)). This also enables the **Scheduler** tab of Fluent Launcher.

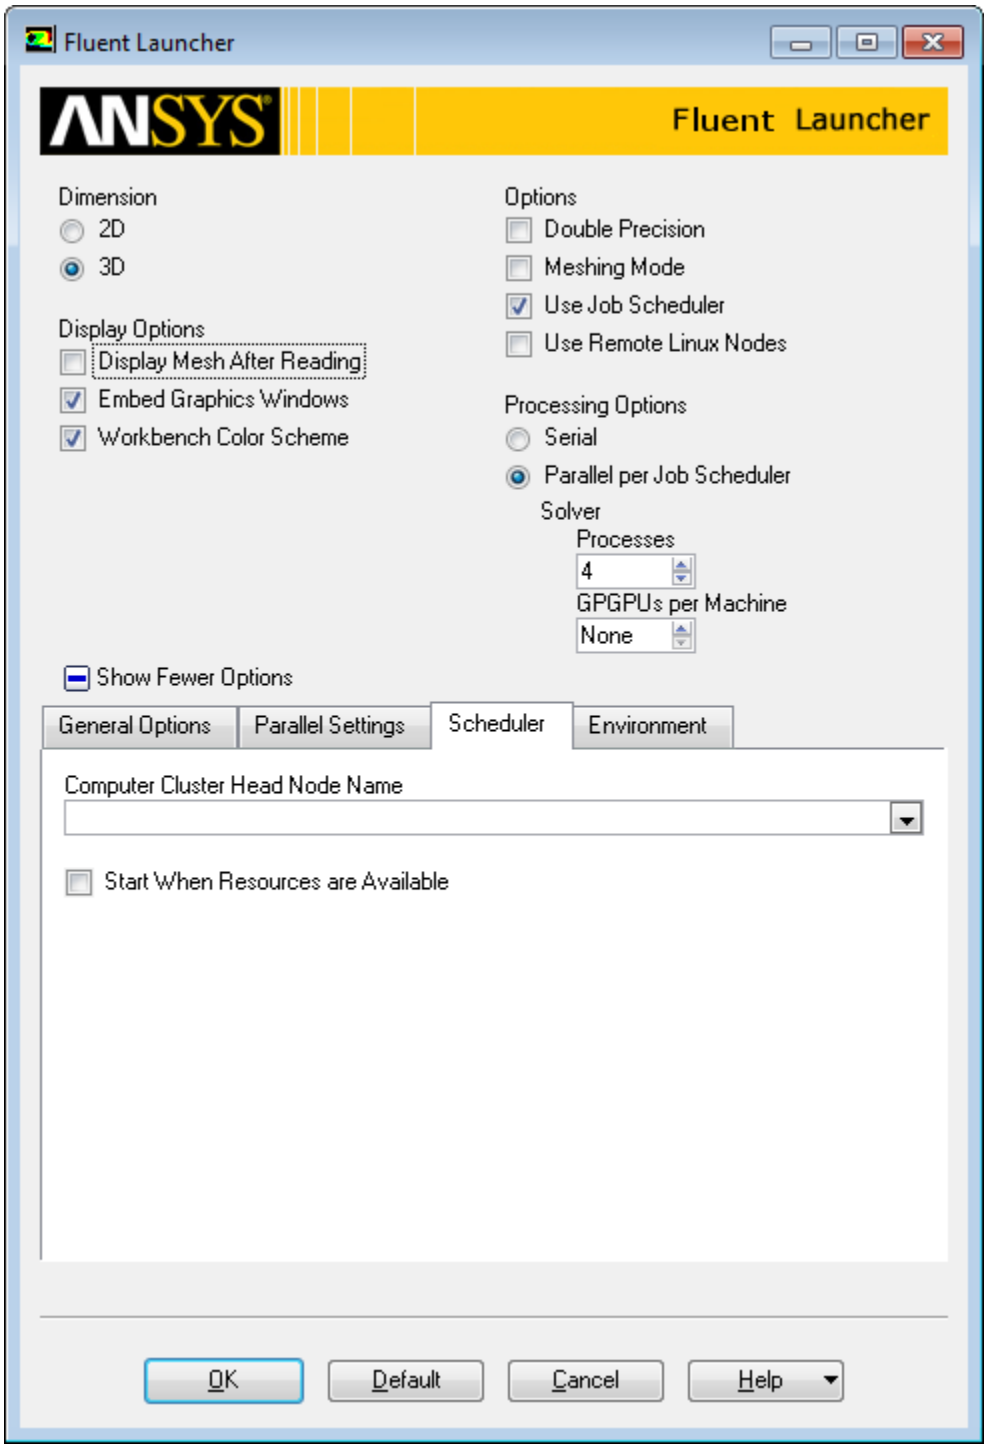
For additional information, see the following sections:
34.2.1. Setting Parallel Scheduler Options in Fluent Launcher
34.2.2. Setting Additional Options When Running on Remote Linux Machines

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.2.1. Setting Parallel Scheduler Options in Fluent Launcher

Activating the **Use Job Scheduler** option under **Options** in Fluent Launcher enables the **Scheduler** tab (visible when you select **Show More Options**). The **Scheduler** tab allows you to specify settings for running ANSYS Fluent with various job schedulers (for example, the Microsoft Job Scheduler for Windows, or LSF, SGE, and PBS Pro on Linux).

Figure 34.4: The Scheduler Tab of Fluent Launcher (Windows 64 Version)



For Windows 64-bit, with MSMPI or when the **Use Remote Linux Nodes** option is selected, you can specify that you want to use the Job Scheduler by selecting the **Use Job Scheduler** check box under

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Options in Fluent Launcher. Once selected, you can then enter a machine name in the **Compute Cluster Head Node Name** text field in the **Scheduler** tab. If you are running ANSYS Fluent on the head node, then you can keep the field empty. This option translates into the proper parallel command line syntax for using the Microsoft Job Scheduler (for details, see Starting Parallel ANSYS Fluent with the Microsoft Job Scheduler (p. 2023)).

If you want ANSYS Fluent to start after the necessary resources have been allocated by the Scheduler, then select the **Start When Resources are Available** check box.

For Linux, select the **Use Job Scheduler** check box under **Options** to use one of three available job schedulers in the **Scheduler** tab.

- Select **Use LSF** to use the LSF load management system with or without checkpointing. If you select **Use Checkpointing**, then you can specify a checkpointing directory in the **Checkpointing Directory** field. By default, the current working directory is used. In addition, you can specify a numerical value for the frequency of automatic checkpointing in the **Automatic Checkpoint with Setting of Period** field.

  For more information, see Setting Job Scheduler Options When Running on Remote Linux Machines (p. 2020) or Part I: Running ANSYS Fluent Under LSF.

- Select **Use SGE** to use the SGE load management system. You can choose to set values for the **SGE qmaster**, as well as the **SGE queue**, or the **SGE pe**. Alternatively, you can select **Use SGE settings** check box and specify the location and name of the SGE configuration file.

  For more information, see Setting Job Scheduler Options When Running on Remote Linux Machines (p. 2020) or Part III: Running ANSYS Fluent Under SGE.

- Select **Use PBS Pro** to use the PBS Pro load management system. You can choose to set the value for **PBS Submission Host** to specify the PBS Pro submission host name for submitting the job, if the machine you are using to run the launcher cannot submit jobs to PBS Pro.

  For more information, see Setting Job Scheduler Options When Running on Remote Linux Machines (p. 2020) or Part II: Running ANSYS Fluent Under PBS Professional.

For Windows, you also have the ability to run in batch mode (using the **Run in Batch Mode** check box) when you provide a journal file (designated in the **General Options** tab) that exits ANSYS Fluent at the end of the run.

For machines running the Windows HPC 2008 Server Scheduler, you also have the following options to choose from:

- **Job Template** allows you to create a custom submission policy to define the job parameters for an application. The cluster administrator can use job templates to manage job submission and optimize cluster usage.

- **Node Group** allows you to specify a collection of nodes. Cluster administrators can create groups and assign nodes to one or more groups.

- **Processor Unit** allows you to choose the following:

  – **Core** refers to a single computing unit in a machine. For example, a quad-core processor has 4 cores.

  – **Socket** refers to a set of tightly integrated cores as on a single chip. Machines often have 2 or more sockets, each socket with multiple cores. A dual CPU, hexcore processor, for example, having a total of 12 cores.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– **Node** refers to a named host, that is, a single machine used as part of a cluster. Typical clusters range from a few to tens, hundreds, or sometimes thousands of machines.

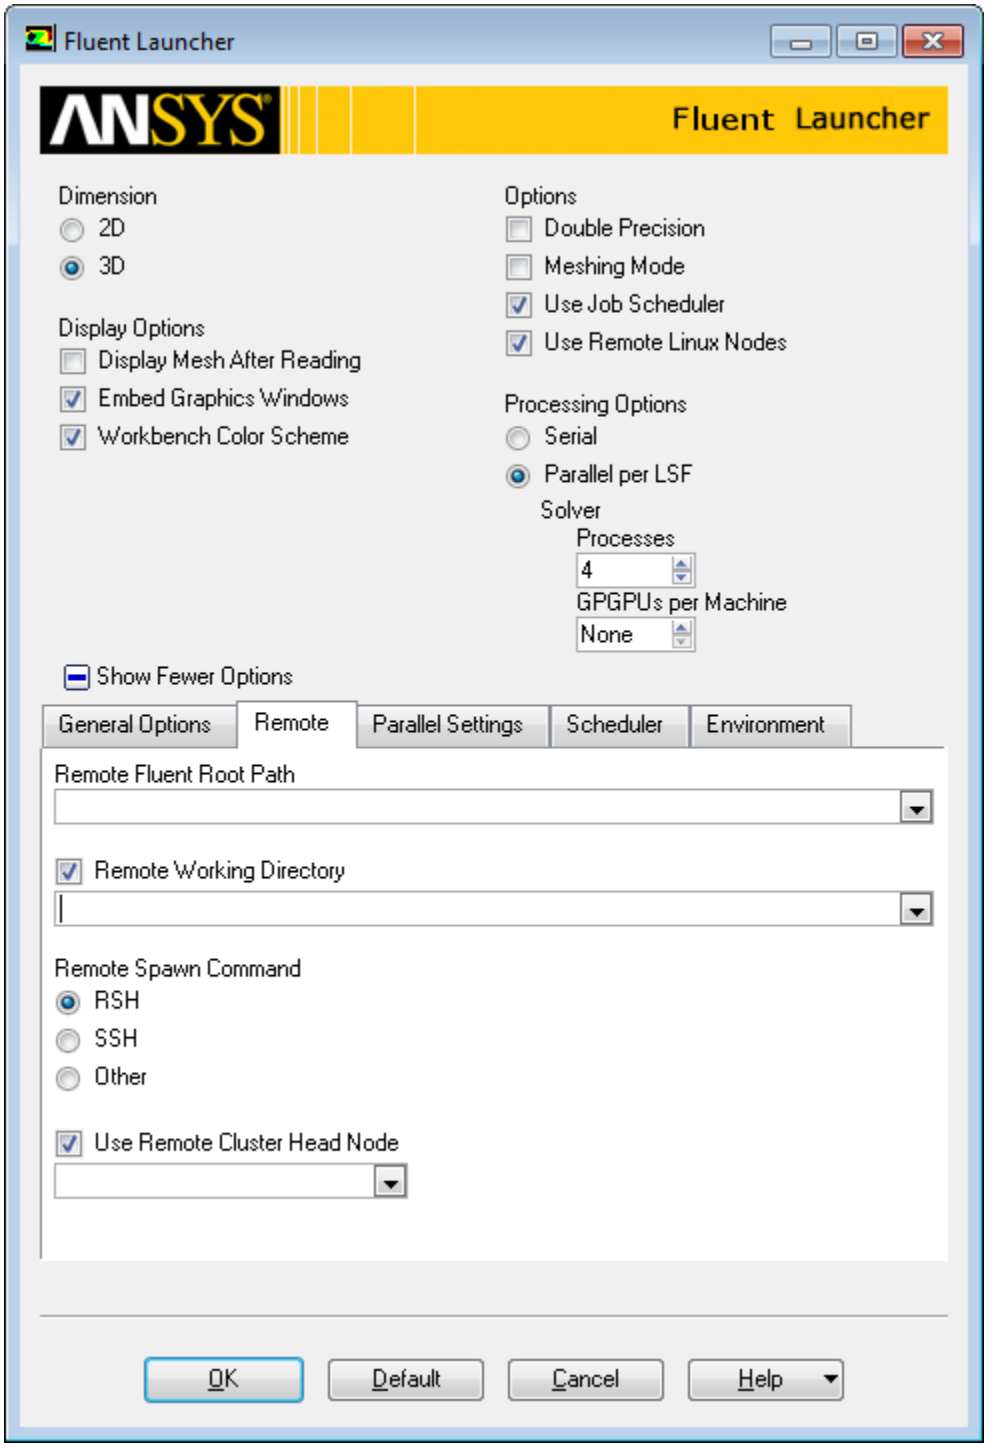
For more information about running Fluent jobs using the Windows HPC 2008 Server Scheduler, see the Frequently Asked Questions section of the Customer Portal.

34.2.2. Setting Additional Options When Running on Remote Linux Machines

The **Remote** tab allows you to specify settings for running ANSYS Fluent parallel simulations on Linux clusters, via the Windows interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.5: The Remote Tab of Fluent Launcher



You can run simulations on Linux machines, either in serial or on parallel Linux clusters, via the Windows interface. To access remote 64-bit Linux clusters for your parallel calculation, select the **Parallel (Local Machine)** option under **Processing Options** (for details, see Setting Parallel Options in Fluent Launcher in the Getting Started Guide), then enable **Use Remote Linux Nodes**, which appears under **Options**. The **Remote** tab in Fluent Launcher will become available, where you can specify the remote ANSYS Fluent Linux installation root path in the **Remote Fluent Root Path** field. The **Remote Working Directory** field allows you to specify a working directory for the remote Linux nodes, other than the default `temp` directory.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select one of the following **Remote Spawn Commands** to connect to the remote node:

- **RSH** will use RSH to spawn nodes from the local Windows machine to the Linux head node as well as from the Linux head node to the compute nodes. If you want the Linux cluster to use SSH, then you must set the `FLUENT_NO_REMOTE_RSH` to `1`. You also must set up password-less access.
- **SSH** (the default) will use SSH to spawn nodes from the local Windows machine to the Linux head node as well as from the Linux head node to the compute nodes. To use SSH with ANSYS Fluent, you must set up password-less SSH access. If you want the Linux cluster to use RSH, then you must set the `FLUENT_NO_REMOTE_SSH` to `1`. For more information about setting up SSH without a password, see www.debian-administration.org/articles/152.
- **Other** allows you to provide other compatible remote shell commands.

Enable the **Use Remote Cluster Head Node** field and specify the remote node to which ANSYS Fluent will connect for spawning (for example, via `rsh` or `ssh`). If this is not provided, then ANSYS Fluent will try to use the first machine in the machine file. If SGE is chosen as the job scheduler, then the **SGE qmaster** will serve the same purpose. If **PBS Pro** is chosen as the job scheduler, then the host specified here should be the PBS Pro submission host.

In addition to using the settings in the **Remote** tab in Fluent Launcher, the following command line options are also available when starting ANSYS Fluent from the command line:

`-nodepath=path`
is the path on the remote machine where ANSYS Fluent is installed.

`-node0=machine name`
is the machine from which to launch other nodes.

`-nodehomedir=directory`
is the directory that becomes the current working directory for all the nodes. Additionally, this will be used as a scratch area for temporary files that are created on the nodes.

`-rsh=remote shell command`
is the command that will be used to launch executables remotely. This option defaults to `ssh.exe` but can point to any equivalent program. The form of this command should be that it should not wait for additional inputs such as passwords. For example, if you install SSH, and try to launch in mixed mode using `ssh`, the launch may fail unless you have set up a login for SSH without a password. For more information about setting up SSH without a password, see www.debian-administration.org/articles/152.

As there are known issues with launching ANSYS Fluent in mixed Windows/Linux mode from cygwin, it is recommended that you use the command prompt (`cmd.exe`).

While ANSYS Fluent case and data files are read from and written to the Windows machine while running mixed Windows/Linux simulations, parallel data files (`.pdat` files) are written by the nodes and will not be available on the Windows machine. Therefore, the path specified for writing `.pdat` files should be a Linux path (you can set node's home directory if you want to provide relative paths). If you use the graphical user interface to read and/or write `.pdat` files, the directory component of the path is ignored and only the file name is used to read and/or write the `.pdat` file relative to the node's current working directory.

When working with mixed Linux and Windows runs that employ user-defined functions (UDFs), you should keep in mind that the file that you have opened for reading/writing on the host machine will not be available on remote nodes and vice-versa. You may therefore have to transfer data present on

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the nodes to the host and write it from host, (or distribute the data from the host to the nodes after reading the data from the host).

34.2.2.1. Setting Job Scheduler Options When Running on Remote Linux Machines

By selecting the **Use Remote Linux Nodes** option and the **Use Job Scheduler** option in Fluent Launcher, you can set job scheduler options for the remote Linux machines you are accessing for your CFD analysis.

When these options are enabled in Fluent Launcher, you can use the **Scheduler** tab to set parameters for either **LSF**, **SGE**, or **PBS Pro** job schedulers. You can learn more about each of the schedulers by referring to the Load Management Documentation.

The following list describes the various controls that are available in the **Scheduler** tab:

Use LSF
allows you to use the LSF job scheduler.

LSF queue
allows you to specify a job queue and enter the queue name in the field.

Use Checkpointing
allows you to use checkpointing with LSF. By default, the checkpointing directory will be the current working directory; however, you have the option of enabling **Checkpointing Directory**.

Checkpointing Directory
allows you to specify a checkpointing directory that is different from the current working directory.

Automatic Checkpoint with Setting of Period
allows you to specify that the checkpointing is done automatically at a set time interval. Enter the period (in minutes) in the field, otherwise checkpointing will not occur unless you call the `bchkpnt` command.

Use SGE
allows you to use the SGE job scheduler.

SGE qmaster
is the machine in the SGE job submission host list. SGE will allow the **SGE qmaster** node to summon jobs. By default, **localhost** is specified for **SGE qmaster**. Note that the button allows you to check the job status.

SGE queue
is the queue where you want to submit your ANSYS Fluent jobs. Note that you can use the button to contact the **SGE qmaster** for a list of queues. Leave this field blank if you want to use the default queue.

SGE pe
is the parallel environment where you want to submit your ANSYS Fluent jobs. The parallel environment must be defined by an administrator. For more information about creating a parallel environment, refer to the SGE documentation. Leave this field blank if you want to use the default parallel environment.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use PBS Pro
allows you to use the PBS Pro job scheduler.

Important

While running on remote Linux machines using any one of the Job Scheduler options, if the submitted job is in the job queue because of unavailable requested resources, then the ANSYS Fluent graphical user interface will remain open until resources are available and the job starts running.

34.3. Starting Parallel ANSYS Fluent on a Windows System

You can run ANSYS Fluent on a Windows system using either the graphical user interface (for details, see Starting Parallel ANSYS Fluent Using Fluent Launcher (p. 2012)) or command line options (for details, see Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options (p. 2021)).

Important

See the separate installation instructions for more information about installing parallel ANSYS Fluent for Windows. The startup instructions below assume that you have properly set up the necessary software, based on the appropriate installation instructions.

Additional information about installation issues can also be found in the Frequently Asked Questions section of the Customer Portal.

For additional information, see the following section:
34.3.1. Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options

34.3.1. Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options

To start the parallel version of ANSYS Fluent using command line options, you can use the following syntax in a Command Prompt window:

`fluent` *version* `-t` *nprocs* `[-gpgpu=` *ngpgpus* `]` `[-p` *interconnect* `]` `[-mpi=` *mpi_type* `]` `[-cnf=` *hosts* `]`

where

- *version* must be replaced by the version of ANSYS Fluent you want to run (`2d`, `3d`, `2ddp`, or `3ddp`).
- `-t` *nprocs* specifies the number of processes to use. When the `-cnf` option is present, the *hosts* argument is used to determine which machines to use for the parallel job. For example, if there are 8 machines listed in the hosts file and you want to run a job with 4 processes, set *nprocs* to 4 (that is, `-t4`) and ANSYS Fluent will use the first 4 machines listed in the hosts file. Note that this does not apply to the Compute Cluster Server (CCS). If the `-gpgpu` option is used, *nprocs* must be chosen such that the number of solver processes per machine is equal on all machines.
- `-p` *interconnect* (optional) specifies the type of interconnect. The `ethernet` interconnect is used by default if the option is not explicitly specified. See Table 34.2: Supported Interconnects for the Windows Plat-

form (p. 2023), Table 34.3: Available MPIs for Windows Platforms (p. 2023), and Table 34.4: Supported MPIs for Windows Architectures (Per Interconnect) (p. 2023) for more information.

- `-mpi=` *mpi_type* (optional) specifies the MPI implementation. If the option is not specified, the default MPI for the given interconnect (IBM MPI) will be used (the use of the default MPI is recommended). The available MPIs for Windows are shown in Table 34.3: Available MPIs for Windows Platforms (p. 2023).

- `-cnf=` *hosts* (optional) specifies the hosts file, which contains a list of the machines on which you want to run the parallel job; if this option is not used, then the session will run on the local machine. If the hosts file is not located in the folder where you are typing the startup command, you must supply the full pathname to the file.

  You can use a plain text editor such as Notepad to create the hosts file. The only restriction on the filename is that there should be no spaces in it. For example, `hosts.txt` is an acceptable hosts file name, but `my hosts.txt` is not.

  Your hosts file (for example, `hosts.txt`) might contain the following entries:

  ```
  machine1
  machine2
  ```

  Important

  The last entry must be followed by a blank line.

  If a machine in the network is a multiprocessor, you can list it more than once. For example, if `machine1` has 2 CPUs, then, to take advantage of both CPUs (and similarly for multicore machines), the `hosts.txt` file should list `machine1` twice:

  ```
  machine1
  machine1
  machine2
  ```

  By default, Fluent allocates ranks to machines in contiguous blocks, where the block sizes are as equal as possible. You can control the per machine block allocation size using the `machine` *X* `:` *Y* convention in the hosts specification, where *Y* is the process block count for `machine` *X*. The process assignment will cycle through the machine list until all processes are allocated in specified blocks. A fully round-robin assignment of processes can be achieved by setting the machine block allocation sizes to 1 (for example, `machine1:1`, `machine2:1`, and so on).

- `-gpgpu=` *ngpgpus* specifies the number of GPGPUs per machine to use for AMG execution. Note that when this option is used, the number of solver process per machine must be equal on all machines and *ngpgpus* must be chosen such that the number of solver processes per machine is an integer multiple of *ngpgpus*. That is, for *nprocs* solver processes running on *M* machines using *ngpgpus* GPGPUS per machine:

  $$nprocs \bmod M = 0$$
  $$\left(\frac{nprocs}{M}\right) \bmod ngpgpus = 0$$

  See Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver (p. 2056) for more information about using GPGPU acceleration.

For example, the full command line to start a 3D parallel job on the first 4 machines listed in a hosts file called `hosts.txt` is as follows:

```
fluent 3d -t4 -cnf=hosts.txt
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

As another example, the full command line to start a 3D symmetrical multiprocessing (SMP) parallel job on 4 machines is as follows:

```
fluent 3d -t4
```

In either case, the default communication library (IBM MPI), and the default interconnect (automatically selected by the MPI used, or `ethernet`) will be used since these options are not specified.

The first time that you try to run ANSYS Fluent in parallel, you will be prompted for information about the current Windows account. For more information about the IBM MPI setup, see the ANSYS Customer Portal (www.ansys.com/customerportal).

The supported interconnects for dedicated parallel `win64` Windows machines, the associated MPIs for them, and the corresponding syntax are listed in Table 34.2: Supported Interconnects for the Windows Platform (p. 2023) - Table 34.4: Supported MPIs for Windows Architectures (Per Interconnect) (p. 2023).

Table 34.2: Supported Interconnects for the Windows Platform

Platform	Processor	Architecture	Interconnects
Windows	64-bit	`win64`	`ethernet` (default), `infiniband`, `myrinet`

Table 34.3: Available MPIs for Windows Platforms

MPI	Syntax (flag)	Communication Library	Notes
`ibmmpi`	`-mpi=ibmmpi`	IBM MPI	(1), (2), (3)
`ms`	`-mpi=ms`	Microsoft MPI	(1)*, (2)
`intel`	`-mpi=intel`	Intel MPI	(1), (2), (4)

(1) Used with Shared Memory Machine (SHM) where the memory is shared between the processors on a single machine.

* Ensure that Microsoft MPI is installed on the machine where the shared memory job will be running.

(2) Used with Distributed Memory Machine (DMM) where each processor has it's own memory associated with it.

(3) IBM Platform MPI Community Edition is installed with Fluent, which is limited to 4096 processes without an additional license. Refer to IBM Platform MPI with High (>4096) Process Count for details.

(4) By default, Intel MPI does not support heterogeneous environments (that is, a mix of operating system versions or hardware) for Windows. As a workaround, you can use the following environment setting:

```
I_MPI_PLATFORM zero
```

Table 34.4: Supported MPIs for Windows Architectures (Per Interconnect)

Architecture	Ethernet	Myrinet	Infiniband
`win64`	`ibmmpi` (default), `intel`, `ms`	`ms`	`ms`

34.3.1.1. Starting Parallel ANSYS Fluent with the Microsoft Job Scheduler

The Microsoft Job Scheduler allows you to manage multiple jobs and tasks, allocate machine resources, send tasks to compute nodes, and monitor jobs, tasks, and compute nodes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Windows Server operating systems include a compute cluster server (CCS) and a high performance computing server (HPC) that combines the Microsoft MPI type (`msmpi`) with the Microsoft Job Scheduler. ANSYS Fluent provides a means of using the Microsoft Job Scheduler using the following flag in the parallel command:

`-ccp` *head-node-name*

where `-ccp` indicates the use of the compute cluster server package, and *head-node-name* indicates the name of the head node of the machine cluster.

For example, if you want to use the Microsoft Job Scheduler to run a 3D model on 2 nodes, the corresponding command syntax would be:

`fluent 3d -t2 -ccp` *head-node-name*

Important

Both the IBM MPI type (`ibmmpi`) and the Intel MPI (`intel`) are not supported with the Microsoft Job Scheduler.

Note

When using Microsoft Job Scheduler, the best interconnect is automatically selected by MS-MPI and the default Ethernet option does not apply.

Though the usage described previously is recommended as an initial starting point for running ANSYS Fluent with the Microsoft Job Scheduler, there are further options provided to meet your specific needs. ANSYS Fluent allows you to do any of the following with the Microsoft Job Scheduler:

- Request resources from the Microsoft Job Scheduler first, before you launch ANSYS Fluent.

  This is done by first submitting a job that will run until canceled, as shown in the following example:

  `job new/scheduler:` *head-node-name* `/numprocessors:2 /rununtilcanceled:true`

  This example requests a 2-node resource on a cluster named *head-node-name*. You will see that a job is created with the job ID *job-id*:

  `job submit/scheduler:` *head-node-name* `/id:` *job-id*

  Then check if the resources have been allocated:

  `job view` *job-id* `/scheduler:` *head-node-name*

  If the resources are ready, you can start ANSYS Fluent using the job ID:

  `fluent 3d -t2 -ccp` *head-node-name* `-jobid=` *job-id*

  This job will be reusable until you decide to cancel it, at which point you must enter the following:

  `job cancel` *job-id* `/scheduler:` *head-node-name*

- Have ANSYS Fluent submit a CCS job, but delay the launching of ANSYS Fluent until the actual resources are allocated.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This is done by specifying the job ID as `-1`, as shown in the following example:

`fluent 3d -t2 -ccp` *head-node-name* `-jobid=-1`

If you want to stop the job application, click the **Cancel** button. ANSYS Fluent will prompt you for confirmation, and then clean up the pending job and exit.

- Run your job using XML template files.

  This is done by first creating an XML template file, such as shown in the following example:

```
<?xml version="1.0" encoding="utf-8"?>
<Job
xmlns:m:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:m:xsd="http://www.w3.org/2001/XMLSchema"
SoftwareLicense=""
MaximumNumberOfProcessors="4"
MinimumNumberOfProcessors="4"
Runtime="Infinite"
IsExclusive="true"
Priority="Normal"
Name="Name_of_job"
Project="Fluent runs"
RunUntilCanceled="false">
<Tasks xmlns:m="http://www.microsoft.com/ComputeCluster/">
 <Task
   MaximumNumberOfProcessors="4"
   MinimumNumberOfProcessors="4"
   Depend=""
   WorkDirectory="\\file-server\home\user"
   Stdout="fluent-case.%CCP_JOBID%.out"
   Stderr="fluent-case.%CCP_JOBID%.err"
   Name="My Task"
   CommandLine="\\head-node\fluent-sharename\win64\fluent.exe 3d -i bsi.jou -t4"
   IsExclusive="true"
   IsRerunnable="false"
   Runtime="Infinite">
 </Task>
</Tasks>
</Job>
```

  where `fluent-sharename` is the name of the shared directory pointing to where ANSYS Fluent is installed (for example, `C:\Program Files\ANSYS Inc\v181\fluent`).

  Important

  Note that you must create a journal file that exits ANSYS Fluent at the end of the run, and refer to it using the `-i` flag in your XML template file (`bs1.jou` in the previous example).

  After you have saved the file and given it a name (for example, `job1.xml`), you can submit the job as shown:

  `job submit /jobfile:job1.xml`

- Run the job in batch mode without displaying the ANSYS Fluent graphical user interface.

  The following is an example of such a batch mode job:

  `job submit /scheduler:` *head-node-name*

  `/numprocessors:2 /workdir:\\file-server\home\user\`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
\\head-node\fluent-sharename\ntbin\win64\fluent.exe 3d -t2 -i bs1.jou
```

where `fluent-sharename` is the name of the shared directory pointing to where ANSYS Fluent is installed (for example, `C:\Program Files\ANSYS Inc\v181\fluent`).

Important

- Note that you must create a journal file that exits ANSYS Fluent at the end of the run, and refer to it using the `-i` flag in your batch mode job submission (`bs1.jou` in the previous example).
- You can start ANSYS Fluent jobs from any machine on which is installed either the full CCP or the CCP client tools, but note that all the machines must have the same version installed.

34.4. Starting Parallel ANSYS Fluent on a Linux System

You can run ANSYS Fluent on a Linux system using either the graphical user interface (for details, see Starting Parallel ANSYS Fluent Using Fluent Launcher (p. 2012)) or command line options (for details, see Starting Parallel ANSYS Fluent on a Linux System Using Command Line Options (p. 2026) and Setting Up Your Remote Shell and Secure Shell Clients (p. 2029)).

For additional information, see the following sections:

34.4.1. Starting Parallel ANSYS Fluent on a Linux System Using Command Line Options
34.4.2. Setting Up Your Remote Shell and Secure Shell Clients

34.4.1. Starting Parallel ANSYS Fluent on a Linux System Using Command Line Options

To start the parallel version of ANSYS Fluent using command line options, you can use the following syntax in a command prompt window:

`fluent` *version* `-t` *nprocs* `[-gpgpu=` *ngpgpus* `] [-p` *interconnect* `] [-mpi=` *mpi_type* `] [-cnf=` *hosts* `]`

where

- *version* must be replaced by the version of ANSYS Fluent you want to run (`2d`, `3d`, `2ddp`, or `3ddp`).
- `-t` *nprocs* specifies the number of processes to use. When the `-cnf` option is present, the *hosts* argument is used to determine which machines to use for the parallel job. For example, if there are 10 machines listed in the hosts file and you want to run a job with 5 processes, set *nprocs* to 5 (that is, `-t5`) and ANSYS Fluent will use the first 5 machines listed in the hosts file. Note that if the `--gpgpu` option is used, *nprocs* must be chosen such that the number of solver processes per machine is equal on all machines.
- `-p` *interconnect* (optional) specifies the type of interconnect. The `auto-select` interconnect is used by default so that the best available interconnect is used if the option is not explicitly specified. See Table 34.5: Supported Interconnects for Linux Platforms (Per Platform) (p. 2028), Table 34.6: Available MPIs for Linux Platforms (p. 2028), and Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect) (p. 2028) for more information.
- `-mpi=` *mpi_type* (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect will be used (the use of the default MPI is recommended). The available MPIs for Linux are shown in Table 34.6: Available MPIs for Linux Platforms (p. 2028).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `-cnf=` *hosts* (optional) specifies the hosts file, which contains a list of the machines on which you want to run the parallel job; if this option is not used, then the session will run on the local machine. If the hosts file is not located in the directory where you are typing the startup command, you must supply the full pathname to the file.

  You can use a plain text editor to create the hosts file. The only restriction on the filename is that there should be no spaces in it. For example, `hosts.txt` is an acceptable hosts file name, but `my hosts.txt` is not.

  Your hosts file (for example, `hosts.txt`) might contain the following entries:

  ```
  machine1
  machine2
  ```

  If a machine in the network is a multiprocessor, you can list it more than once. For example, if `machine1` has 2 CPUs, then, to take advantage of both CPUs, the `hosts.txt` file should list `machine1` twice:

  ```
  machine1
  machine1
  machine2
  ```

  As an alternative to a hosts file, you can simply type the names of the machines in a list separated by commas, as shown in the following example: `-cnf=machine1,machine1,machine2`.

  By default, Fluent allocates ranks to machines in contiguous blocks, where the block sizes are as equal as possible. You can control the per machine block allocation size using the `machine` *X* `:` *Y* convention in the hosts specification, where *Y* is the process block count for `machine` *X*. The process assignment will cycle through the machine list until all processes are allocated in specified blocks. A fully round-robin assignment of processes can be achieved by setting the machine block allocation sizes to 1 (for example, `machine1:1`, `machine2:1`, and so on).

- `-gpgpu=` *ngpgpus* specifies the number of GPGPUs per machine to use for AMG execution. Note that when this option is used, the number of solver process per machine must be equal on all machines and *ngpgpus* must be chosen such that the number of solver processes per machine is an integer multiple of *ngpgpus*. That is, for *nprocs* solver processes running on *M* machines using *ngpgpus* GPGPUS per machine:

  $$nprocs \bmod M = 0$$
  $$\left(\frac{nprocs}{M}\right) \bmod ngpgpus = 0$$

  See Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver (p. 2056) for more information about using GPGPU acceleration.

For example, to use the Infiniband interconnect, and to start the 3D solver with 4 compute nodes on the machines defined in the text file called `fluent.hosts`, you can enter the following in the command prompt:

```
fluent 3d -t4 -pinfiniband -cnf=fluent.hosts
```

Note that if the optional `-cnf=` *hosts* is specified, a compute node will be spawned on each machine listed in the file *hosts*.

Also, ANSYS Fluent provides a fault-tolerance feature on Infiniband Linux clusters running OFED. To invoke this feature, use the command line flag `-pinfiniband.ofedft` (or `-pib.ofedft`), which enables transparent port fail-over and high-availability features using the IBM MPI. Note that while the simulations proceed more robustly with this option, there may be some degradation in performance.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

During startup, ANSYS Fluent will create very small text files in the `/tmp` area. If you would like to specify a different location for these files, set the following environment variable: `export FL_TMPDIR=` *directory*.

The supported interconnects for parallel Linux machines are listed below (Table 34.5: Supported Interconnects for Linux Platforms (Per Platform) (p. 2028), Table 34.6: Available MPIs for Linux Platforms (p. 2028), and Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect) (p. 2028)), along with their associated communication libraries, the corresponding syntax,

Table 34.5: Supported Interconnects for Linux Platforms (Per Platform)

Platform	Processor	Architecture	Interconnects/Systems*
Linux	64-bit	`lnamd64`	`ethernet`, `infiniband`, `myrinet`

(*) Node processes on the same machine communicate by shared memory. ANSYS Fluent lets the MPI autoselect the best interconnect available on the system. Users can specify an interconnect to override that selection. Ethernet is the fallback choice.

Table 34.6: Available MPIs for Linux Platforms

MPI	Syntax (flag)	Communication Library	Notes
`ibmmpi`	`-mpi=ibmmpi`	IBM MPI	General purpose for SMPs and clusters (1)
`intel`	`-mpi=intel`	Intel MPI	General purpose for SMPs and clusters
`openmpi`	`-mpi=openmpi`	Open MPI	Open source MPI-2 implementation. For both SMPs and clusters.
`cray`	`-mpi=cray`	Cray MPI (MPT)	Only available on Cray systems.

(1) IBM Platform MPI Community Edition is installed with Fluent, which is limited to 4096 processes without an additional license. Refer to IBM Platform MPI with High (>4096) Process Count for details.

Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect)

Architecture	Ethernet	Myrinet*	Infiniband	Proprietary Systems	Omni-Path****
`lnamd64`	`ibmmpi` (default), `intel`, and `openmpi`	`ibmmpi` (default), `openmpi`**	`ibmmpi` (default), `intel`, and `openmpi`	Cray***	`intel`

(*) Both MX and GM Myrinet protocols are supported. ANSYS Fluent will automatically detect which type is running on the system and will use that particular protocol. You only have to supply the `-pmyrinet` option. If the hardware supports it, the installation and usage of Myrinet MX is recommended (consult your Myrinet vendor for applicability).

(**) The OpenMPI version packaged with ANSYS Fluent does not support Myrinet. However, you can use a local version of OpenMPI with Myrinet support.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(***) Using the Cray platform, the Extreme Scalability Mode (ESM) option is used by default, employing the native Cray MPI (MPT) library for parallel communication. Optionally, you can use the Cluster Compatibility Mode (CCM) mode, in which the standard IBM MPI library is used for parallel communication. For simulations with high core counts (for example, above 1000 cores), the ESM mode is recommended for better performance. Note that when using MPT version 5.0 and higher (up to, but not including 7.0), you must set the following environment variable: `export FLUENT_USE_CRAY_MPT5=1`.

(****) Omni-Path requires OFED driver version 10.2 or higher.

(Linux Only) To enable a job scheduler supported native remote node access mechanism, you can use the `-scheduler_rsh` command line flag or set the environment variable SCHEDULER_RSH=1. This tight integration is only supported for the MPI/Job scheduler combinations listed below:

- IBM MPI + LSF
- Intel MPI + LSF
- Intel MPI + UGE
- Intel MPI + PBS Pro

34.4.2. Setting Up Your Remote Shell and Secure Shell Clients

For cluster computing on Linux systems, most parallel versions of ANSYS Fluent will require the user account set up such that you can connect to all nodes on the cluster (using either the remote shell (`rsh`) client or the secure shell (`ssh`) client) without having to enter a password each time for each machine.

Provided that the appropriate server daemons (either `rshd` or `sshd`) are running, this section briefly describes how you can configure your system in order to use ANSYS Fluent for parallel computing.

34.4.2.1. Configuring the `rsh` Client

The remote shell client (`rsh`), is widely deployed and used. It is generally easy to configure, and involves adding all the machine names, each on a single line, to the `.rhosts` file in your home directory.

If you refer to the machine you are currently logged on as the 'client', and if you refer to the remote machine to which you seek password-less login as the 'server', then on the server, you can add the name of your client machine to the `.rhosts` file. The name could be a local name or a fully qualified name with the domain suffix. Similarly, you can add other clients from which you require similar access to this server. These machines are then "trusted" and remote access is allowed without the further need for a password. This setup assumes you have the same user ID on all the machines. Otherwise, each line in the `.rhosts` file must contain the machine name as well as the user ID for the client that you want access to. Refer to your system documentation for further usage options.

Note that for security purposes, the `.rhosts` file must be readable only by the user.

34.4.2.2. Configuring the `ssh` Client

The secure shell client (`ssh`), is a more secure alternative than `rsh` and is also used widely. Depending on the specific protocol and the version deployed, configuration involves a few steps. SSH1 and SSH2 are two current protocols. `OpenSSH` is an open implementation of the SSH2 protocol and is backwards compatible with the SSH1 protocol. To add a client machine, with respect to user configuration, the following steps are involved:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Generate a public-private key pair using `ssh-keygen` (or using a graphical user interface client). For example:

   ```
   % ssh-keygen -t dsa
   ```

   where it creates a Digital Signature Authority (DSA) type key pair.

2. Place your public key on the remote host.

   - For SSH1, insert the contents of the client (`~/.ssh/identity.pub`) into the server (`~/.ssh/authorized_keys`).
   - For SSH2, insert the contents of the client (`~/.ssh/id_dsa.pub`) into the server (`~/.ssh/authorized_keys2`).

The client machine is now added to the access list and you are no longer required to type in a password each time. For additional information, consult your system administrator or refer to your system documentation.

34.5. Mesh Partitioning and Load Balancing

Information about mesh partitioning and load balancing is provided in the following sections:

34.5.1. Overview of Mesh Partitioning
34.5.2. Partitioning the Mesh Automatically
34.5.3. Partitioning the Mesh Manually and Balancing the Load
34.5.4. Using the Partitioning and Load Balancing Dialog Box
34.5.5. Mesh Partitioning Methods
34.5.6. Checking the Partitions
34.5.7. Load Distribution
34.5.8. Troubleshooting

34.5.1. Overview of Mesh Partitioning

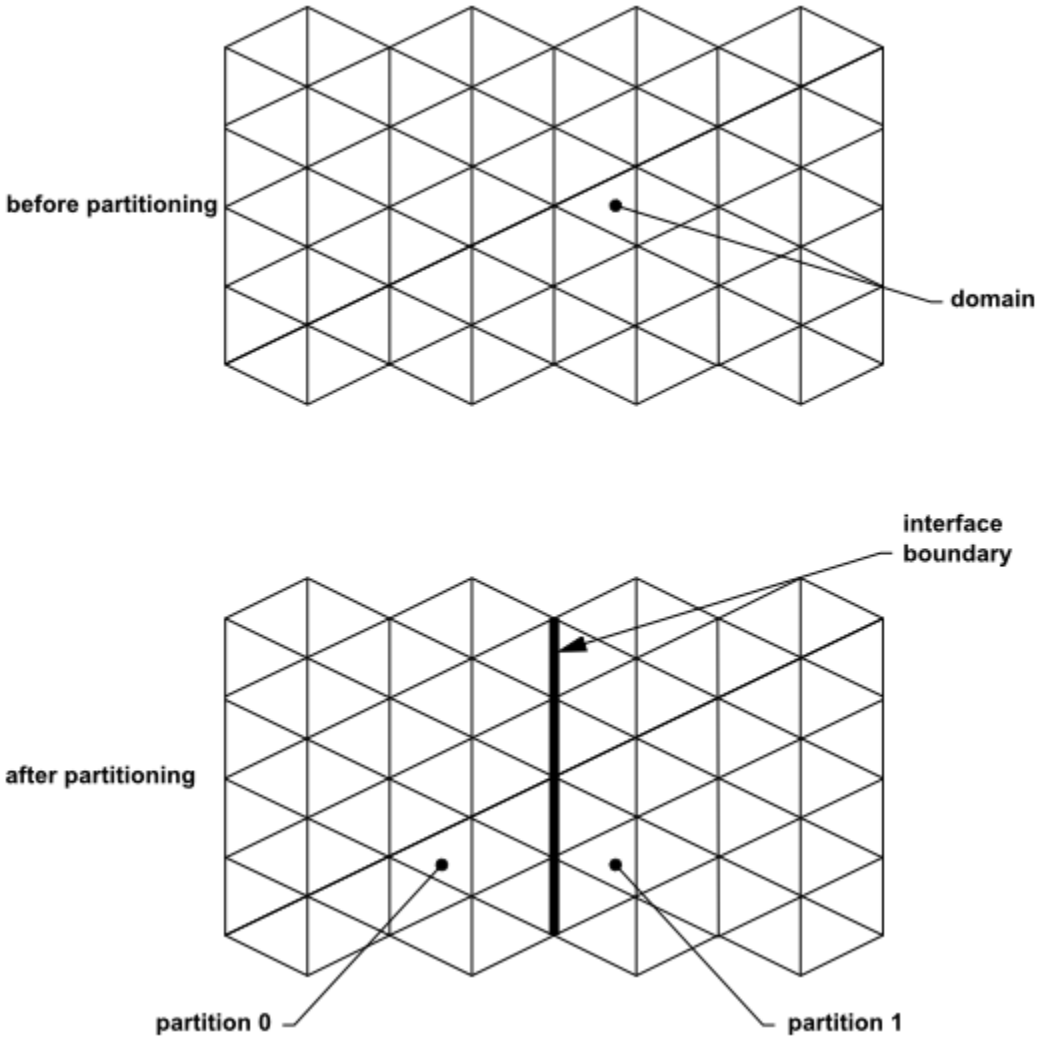
When you use the parallel solver in ANSYS Fluent, you must partition or subdivide the mesh into groups of cells that can be solved on separate processors (see Figure 34.6: Partitioning the Mesh (p. 2031)). You can either use the automatic partitioning algorithms when reading an unpartitioned mesh into the parallel solver (recommended approach, described in Partitioning the Mesh Automatically (p. 2031)), or perform the partitioning yourself in the serial solver or after reading a mesh into the parallel solver (as described in Partitioning the Mesh Manually and Balancing the Load (p. 2033)). In either case, the available partitioning methods are those described in Mesh Partitioning Methods (p. 2046). You can partition the mesh before or after you set up the problem (by defining models, boundary conditions, and so on).

Note that the relative distribution of cells among compute nodes will be maintained during mesh adaption, so manual repartitioning after adaption is not required. For details, see Load Distribution (p. 2055).

If you use the serial solver to set up the problem before partitioning, the machine on which you perform this task must have enough memory to read in the mesh. If your mesh is too large to be read into the serial solver, you can read the unpartitioned mesh directly into the parallel solver (using the memory available in all the defined hosts) and have it automatically partitioned. In this case you will set up the problem after an initial partition has been made. You will then be able to manually repartition the case if necessary. See Partitioning the Mesh Automatically (p. 2031) and Partitioning the Mesh Manually and Balancing the Load (p. 2033) for additional details and limitations, and Checking the Partitions (p. 2052) for details about checking the partitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.6: Partitioning the Mesh



34.5.2. Partitioning the Mesh Automatically

For automatic mesh partitioning, you can select the partition method and other options for creating the mesh partitions before reading a case file into the parallel version of the solver. For some of the methods, you can perform pretesting to ensure that the best possible partition is performed. See Mesh Partitioning Methods (p. 2046) for information about the partitioning methods available in ANSYS Fluent.

Note

Architecturally aware partitioning (see Partitioning (p. 2033)) is performed automatically when the case file is read. If the maximum inter-machine communication is reduced by more than 5%, the new partition mapping will be applied, and a message is displayed in the console, for example:

```
inter-node communication reduction by architecture-aware remapping:
47%
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

While the message indicates actual point-to-point network traffic reduction, solver computational performance improvement may be somewhat less, and depends on the case and the system network configuration.

The procedure for partitioning automatically in the parallel solver is as follows:

1. (optional) Set the partitioning parameters in the **Auto Partition Mesh** dialog box (Figure 34.7: The Auto Partition Mesh Dialog Box (p. 2032)).

   Parallel → General → Auto Partition...

   Figure 34.7: The Auto Partition Mesh Dialog Box

   
   If you are reading in a mesh file or a case file for which no partition information is available, and you keep the **Case File** option turned on, ANSYS Fluent will partition the mesh using the method displayed in the **Method** drop-down list.

   If you want to specify the partitioning method and associated options yourself, the procedure is as follows:

   a. Turn off the **Case File** option. The other options in the dialog box will become available.

   b. Select the partition method in the **Method** drop-down list. The choices are the techniques described in Partition Methods (p. 2046).

   c. You can choose to independently apply partitioning to each cell zone, or you can allow partitions to cross zone boundaries using the **Across Zones** check button. It is recommended that you *not* partition cells zones independently (by turning off the **Across Zones** check button) unless cells in different zones will require significantly different amounts of computation during the solution phase (for example, if the domain contains both solid and fluid zones).

   d. If you have chosen the **Principal Axes** or **Cartesian Axes** method, you can improve the partitioning by enabling the automatic testing of the different bisection directions before the actual partitioning occurs. To use pretesting, turn on the **Pre-Test** option. Pretesting is described in Pretesting (p. 2051).

   e. Click **OK**.

   If you have a case file where you have already partitioned the mesh, and the number of partitions divides evenly into the number of compute nodes, you can keep the default selection of **Case File** in the **Auto Partition Mesh** dialog box. This instructs ANSYS Fluent to use the partitions in the case file.

2. Read the case file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File → Read → Case...

34.5.2.1. Reporting During Auto Partitioning

As the mesh is automatically partitioned, some information about the partitioning process will be displayed in the console. If you want additional information, you can display a report from the **Partitioning and Load Balancing** dialog box after the partitioning is completed.

Parallel → General → Partition/Load Balance...

When you click the **Print Active Partitions** or **Print Stored Partitions** button in the **Partitioning and Load Balancing** dialog box, ANSYS Fluent will display the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each active or stored partition in the console. In addition, it will display the minimum and maximum cell, face, interface, and face-ratio variations. For details, see Interpreting Partition Statistics (p. 2052). You can examine the partitions graphically by following the directions in Checking the Partitions (p. 2052).

34.5.3. Partitioning the Mesh Manually and Balancing the Load

Automatic partitioning in the parallel solver (described in Partitioning the Mesh Automatically (p. 2031)) is the recommended approach to mesh partitioning, but it is also possible to partition the mesh manually in either the serial solver or the parallel solver. After automatic or manual partitioning, you will be able to inspect the partitions created (for details, see Checking the Partitions (p. 2052)) and optionally repartition the mesh, if necessary. Again, you can do so within the serial or the parallel solver, using the **Partitioning and Load Balancing** dialog box. A partitioned mesh may also be used in the serial solver without any loss in performance.

34.5.3.1. Guidelines for Partitioning the Mesh

The following steps are recommended for partitioning a mesh manually:

1. Partition the mesh using the default method (**Metis**). Metis will generally produce the best quality partitions for most problems and no further user intervention should be necessary.

2. Examine the partition statistics, which are described in Interpreting Partition Statistics (p. 2052). Your aim is to achieve small magnitudes for Minimum, Maximum, and Total `Partition boundary face count ratio` while maintaining a balanced load (`Mean cell count variation`). If the statistics are not acceptable, try one of the other partition methods.

Instructions for manual partitioning are provided below.

34.5.4. Using the Partitioning and Load Balancing Dialog Box

34.5.4.1. Partitioning

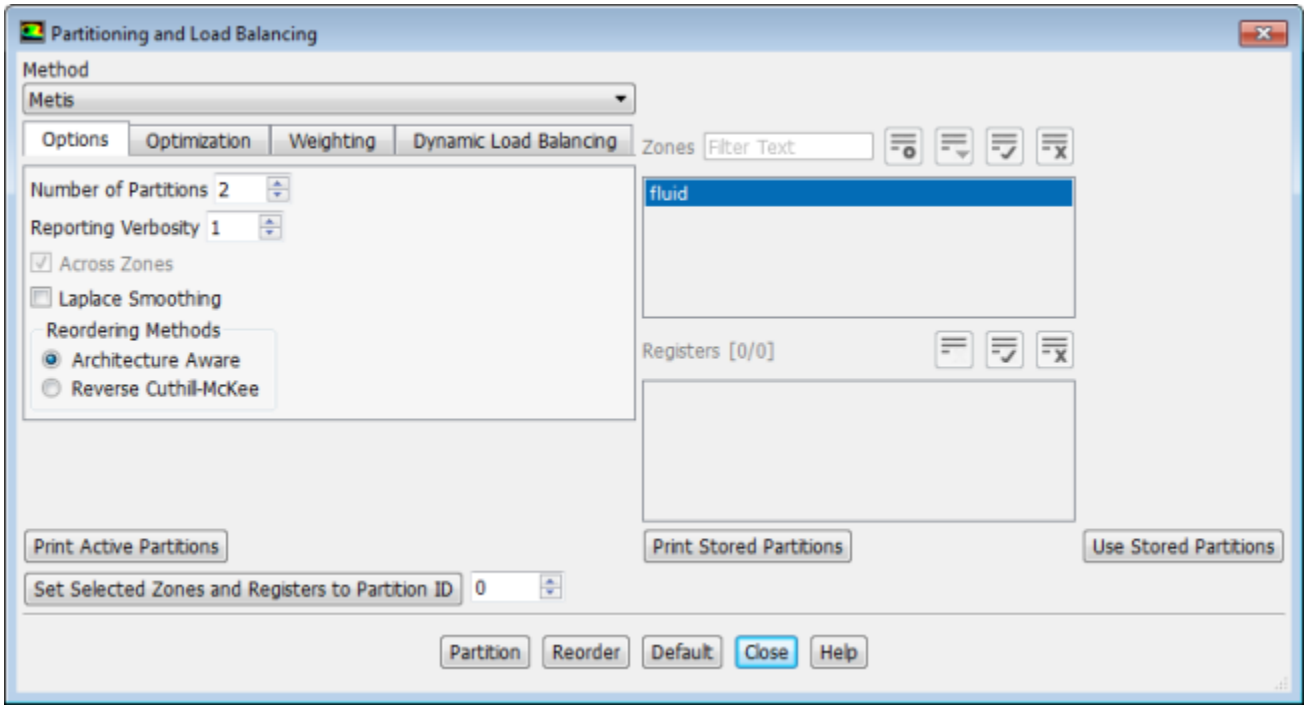
In order to partition the mesh, you must select the partition method for creating the mesh partitions, set the number of partitions, select the zones and/or registers, and choose the optimizations to be used. For some methods, you can also perform pretesting to ensure that the best possible partition is performed. Once you have set all the parameters in the **Partitioning and Load Balancing** dialog box to your satisfaction, click the **Partition** button to subdivide the mesh into the selected number of partitions using the prescribed method and optimization(s). For recommended partitioning strategies see Guidelines for Partitioning the Mesh (p. 2033).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set the relevant inputs in the **Partitioning and Load Balancing** dialog box (Figure 34.8: The Partitioning and Load Balancing Dialog Box in the Parallel Solver (p. 2034) in the parallel solver, or Figure 34.9: The Partitioning and Load Balancing Dialog Box in the Serial Solver (p. 2035) in the serial solver) in the following manner:

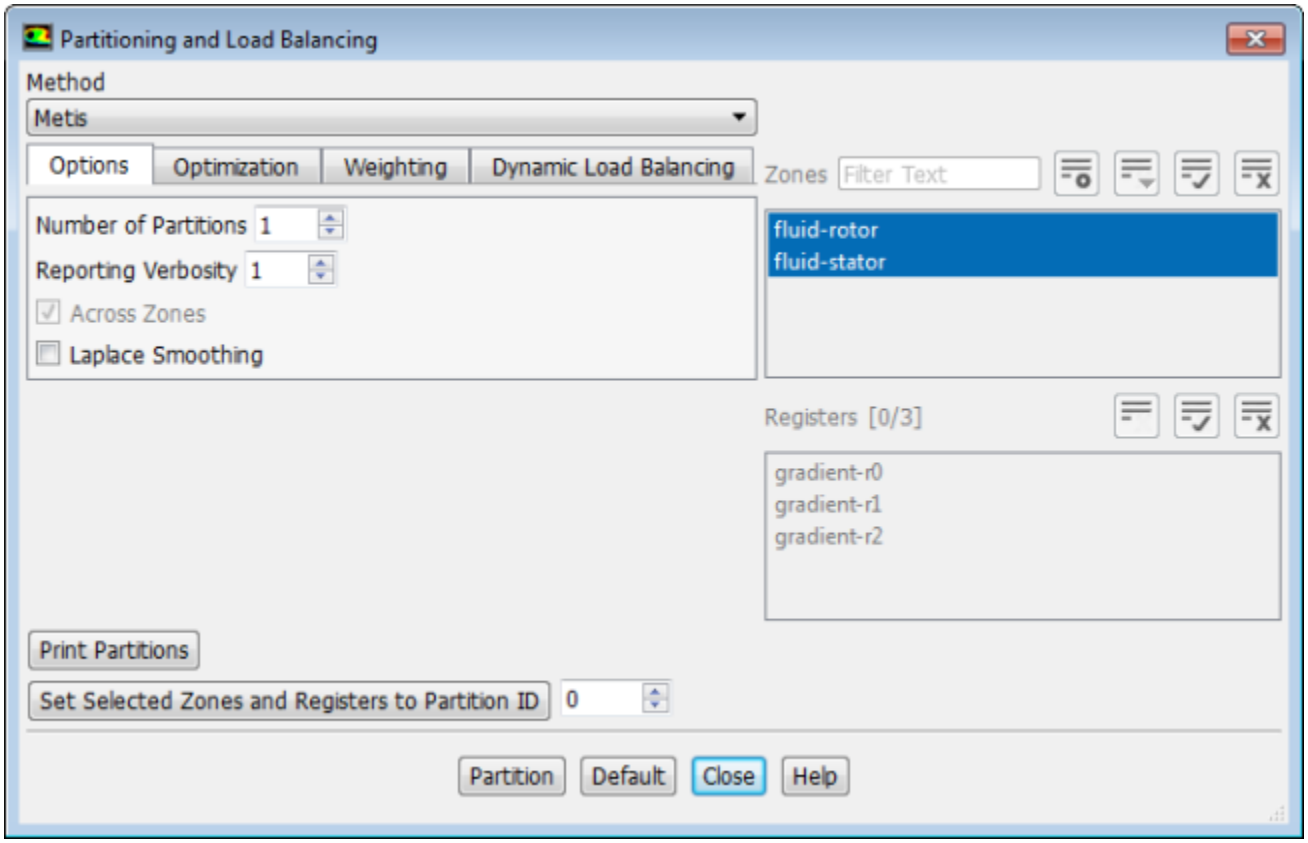
Parallel → General → Partition/Load Balance...

Figure 34.8: The Partitioning and Load Balancing Dialog Box in the Parallel Solver



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.9: The Partitioning and Load Balancing Dialog Box in the Serial Solver



1. Select the **Method** from the drop-down list. The choices are described in Partition Methods (p. 2046).

2. In the **Options** tab

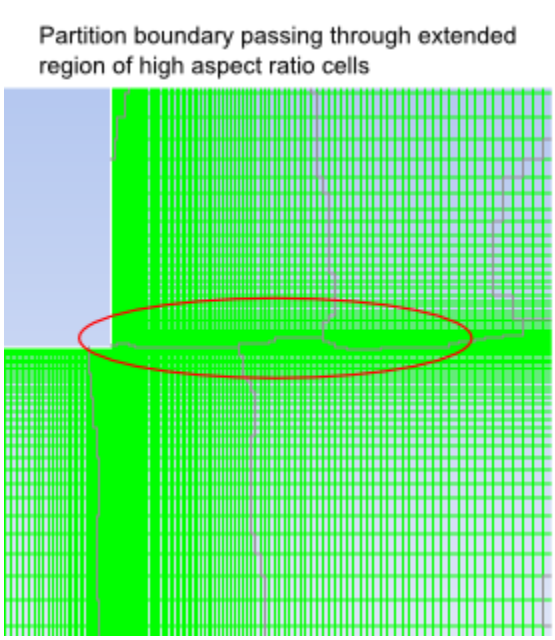
   a. Set the desired number of mesh partitions in the **Number of Partitions** field. You can use the counter arrows to increase or decrease the value, instead of typing in the box. The number of mesh partitions must be an integer number that is divisible by the number of processors available for parallel computing.

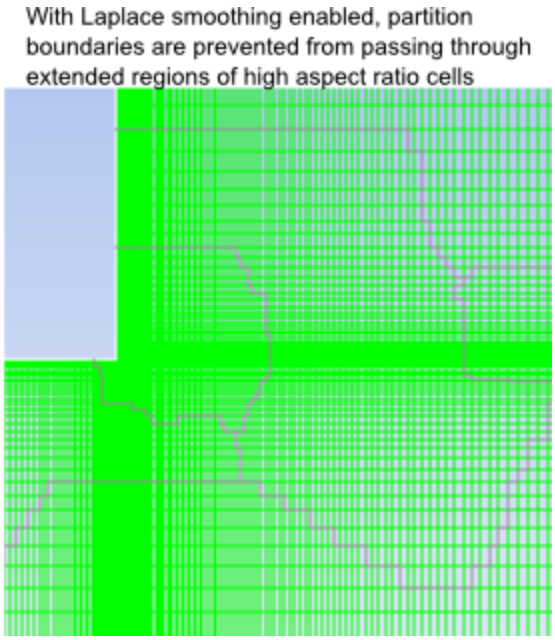
   b. Set the **Reporting Verbosity**. This allows you to control what is displayed in the console. For details, see Reporting During Partitioning (p. 2043).

   c. By default, partitioning will be done across cell zones. You can choose to independently apply partitioning to each cell zone, by disabling **Across Zones**. This is not recommended unless cells in different zones will require significantly different amounts of computation during the solution phase (for example, if the domain contains both solid and fluid zones).

   d. If you are using the **Metis** method, you have the option of enabling **Laplace Smoothing**. This option can be used to prevent partition boundaries from passing through areas of high aspect ratio cells. This can improve convergence in dynamic mesh cases and other cases with regions of highly stretched cells. After enabling Laplace Smoothing, you can specify the **Cutoff Aspect Ratio**. The Cutoff Aspect Ratio corresponds roughly to the maximum aspect ratio allowable along a partition boundary.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





e. Select the **Reordering Method** for partitions to optimize parallel performance:

- **Architecture Aware**: This is the default option and it accounts for the system architecture and network topology in remapping the partitions to the processors.
- **Reverse Cuthill-McKee**: This option minimizes the bandwidth of the compute-node connectivity matrix (the maximum distance between two connected processes) without incorporating the system architecture.

The reordering methods are parallel performance tuning options. After the case is initially partitioned for parallel processing, the partition reordering step will remap the partitions in a more optimal way to improve parallel performance.

Important

The Architecture-aware reordering method is not applicable when only a single machine is used for the simulation.

After initially loading the case into a parallel session, you can click the **Reorder** button to reorder the partitions. The necessary algorithms are executed and ANSYS Fluent will report if it can find a more optimal mapping for the partitions, as well as the potential improvement in inter-machine communications. If the reported improvement is significant (say, more than 5%), then you can click the **Use Stored Partitions** button to use the new partition mapping. This will generally entail large data transfers amongst all the processes, and another reliable method to use the new partitions would be to write out a case file and load it back in to a new parallel session. The process is similar to re-partitioning with a new partitioning method, for example. Note that sometimes, depending on the cluster configuration and initial case partitioning, and if the partitions have already been reordered, no improvement is possible, and this will be reported in the console after clicking the **Reorder** button. You can simply continue in this case, and there will be no effect on the simulation. Also, note that partition reordering is specific to the current parallel configuration and should be repeated if the number of machines used changes during subsequent computations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the **Optimization** tab

   a. You can enable and control the desired optimization methods (described in Optimizations (p. 2050)). You can enable the **Merge** and **Smooth** schemes by enabling the check button next to each one. For each scheme, you can also set the number of **Iterations**. Each optimization scheme will be applied until appropriate criteria are met, or the maximum number of iterations has been executed. If the **Iterations** counter is set to 0, the optimization scheme will be applied until completion, with no limit on maximum number of iterations.

   b. Choosing the **Principal Axes** or **Cartesian Axes** method, you can improve the partitioning by enabling the automatic testing of the different bisection directions before the actual partitioning occurs. To use pretesting, enable the **Pre-Test** option. Pretesting is described in Pretesting (p. 2051).

4. In the **Zones** and/or **Registers** lists, select the zone(s) and/or register(s) for which you want to partition. For most cases, you will select all **Zones** (the default) to partition the entire domain. See below for details.

5. You can assign selected **Zones** and/or **Registers** to a specific partition ID by entering a value for the **Set Selected Zones and Registers to Partition ID**. For example, if the **Number** of partitions for your mesh is 2, then you can only use IDs of 0 or 1. If you have three partitions, then you can enter IDs of 0, 1, or 2. This can be useful in situations where the gradient at a region is known to be high. In such cases, you can mark the region or zone and set the marked cells to one of the partition IDs, thereby preventing the partition from going through that region. This in turn will facilitate convergence. This is also useful in cases where mesh manipulation tools are not available in parallel. In this case, you can assign the related cells to a particular ID so that the mesh manipulation tools are now functional.

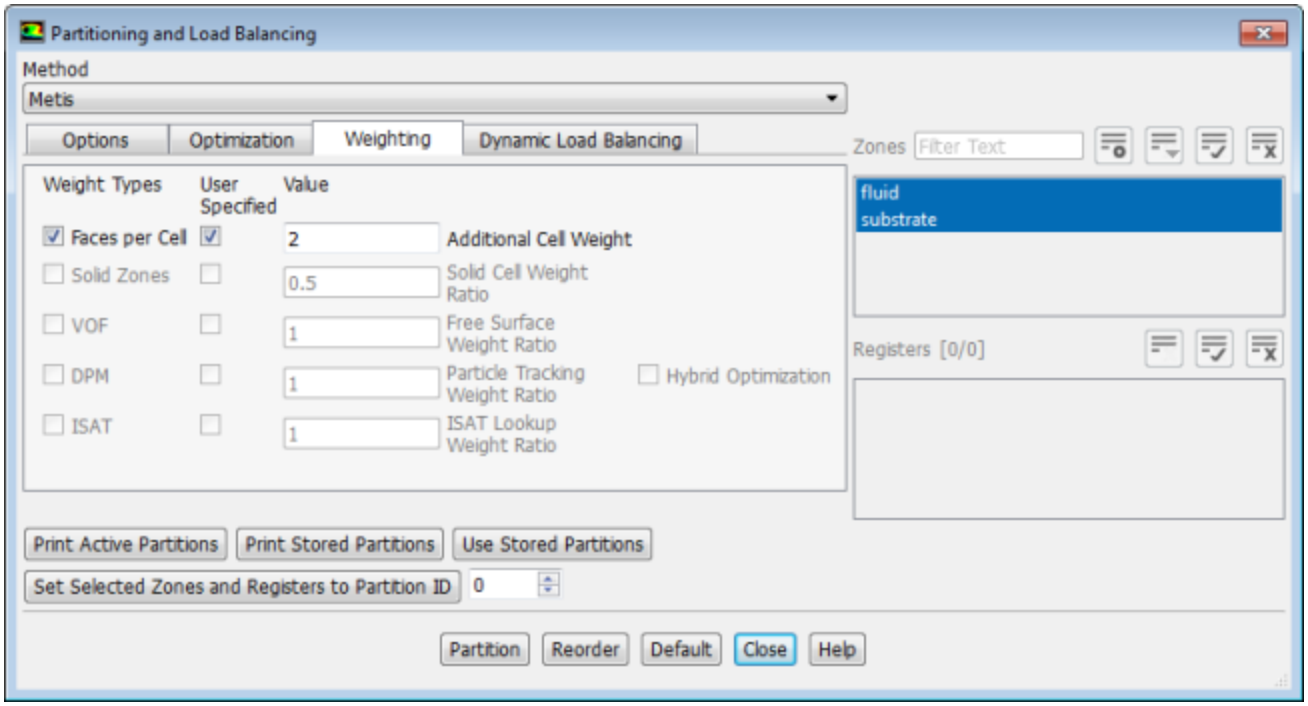
   If you are running the parallel solver, and you have marked your region and assigned an ID to the selected **Zones** and/or **Registers**, click the **Use Stored Partitions** button to make the new partitions valid.

   Refer to the example described later in this section for a demonstration of how selected registers are assigned to a partition (Example of Setting Selected Registers to Specified Partition IDs (p. 2040)).

6. In the **Weighting** tab (Figure 34.10: The Weighting Tab in the Partitioning and Load Balancing Dialog Box for the Parallel Solver (p. 2038)), you can set the appropriate weights prior to partitioning the mesh, to improve load balancing and overall performance. You can control weights for cells, solid zones, VOF, DPM, and ISAT table lookup. You can either rely on ANSYS Fluent timers to set the weight scaling, specify the value by enabling **User-Specified**, or use model-weighted partitioning (so that Fluent automatically calculates the weighting based on the cell count and the models and attributes used as weights).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.10: The Weighting Tab in the Partitioning and Load Balancing Dialog Box for the Parallel Solver



a. Enable **Faces per Cell** so that the partitioning assigns a weight to each cell based on its number of faces. This type of weighting is advantageous when the case has mixed or polyhedral cell zones. If you enable the **User-Specified** check box, the weight assigned to each cell will be the number of faces plus the **Additional Cell Weight** you enter in the number-entry box under **Value**. By default the **Faces per Cell** weighting is enabled with the **Additional Cell Weight** set to **2**.

b. Enable **Solid Zones** weighting to allow the partitioning to take solid zones into consideration. By default, ANSYS Fluent will scale the weight based on the computational time of the solid and fluid zones. If an iteration has not been run, then you may need to specify a value after enabling the user-specified check box. The value you enter is relative to the fluid weight. Typically, it should be less than `1` (for example, `0.0001`) so that the calculation will be quicker for the solid zone compared to the fluid zone. Entering a value greater than `1` for the **Solid Zones** means that the calculation will take longer and will be more computationally expensive for the solid zone compared to the fluid zone.

Important

Setting the **Solid Zones** either too high or too low can cause a load imbalance, depending on which equations are being solved. If you are not sure what would be an appropriate value, have ANSYS Fluent automatically set it for you by making sure that **User-Specified** is disabled.

---

c. Enable **VOF** weighting to allow the partitioning to consider the imbalance caused by the free surface reconstruction with the geo-reconstruct scheme. Therefore, it is only available when using the VOF model with geometric reconstruction. You may use the user-specified value before timers are collected, or if you want to specify a value other than timing statistics. The specified value is the VOF proportion of the total computational effort.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. Enable **DPM** weighting to set the weight of DPM particles relative to the continuous phase. DPM weights are valid when you have particle tracking in your simulation, where the user-specified value is the DPM proportion of the total computational effort relative to the continuous phase. Note that this is available only when you have injections defined. For details, see Modeling Discrete Phase (p. 1235).

   The DPM weight takes into account the distribution of the tracking effort over the partitions and it is available after at least one calculation step with particle tracking. Displaying Particle Tracks does not change the weights. The computational effort is determined by the number of DPM steps performed in each cell. This weight becomes more important when the time for the particle tracking of particles exceeds the time for solving the flow. Enabling this option in the **Weighting** tab enables the counting of the particle steps in the cells. These values are available for contour and vector plots when using the **Discrete Phase Model** and **DPM Steps per Cell** variable. After repartitioning, the DPM weights are reset before the next particle tracking. It is generally preferable to partition along the dominant path of the particles in order to minimize particles crossing partition boundaries and thereby reducing associated communication costs. However, partitioning should also consider load balance for the other models, especially the continuous phase, and model weighting provides a means to effectively load balance the overall simulation.

   Select the **Hybrid Optimization** option to enable the hybrid optimization partition weighting method for DPM. This method balances the load across machines, and, within each machine, the hybrid parallel DPM method is used to make sure the load is balanced by multi-threading. First, the domain is split based on the model weights of each cell and then partitioned across a number of machines. Finally, each machine is partitioned according to the number of cores. This allows you to have a balanced number of cells in each partition, at the same time having a balanced number of particles on each machine, which will be further balanced by the hybrid DPM method. This optimization option is also applicable to the discrete element method (DEM) collision model.

e. Enable **ISAT** weighting to balance the load during the ISAT table lookup for the stiff-chemistry Laminar, EDC or PDF Transport models. The ISAT algorithm builds an unstructured table in N species dimensions for storage and retrieval of the chemistry mappings. Since chemistry is usually computationally expensive, this storage/retrieval can be very time-consuming (for information about ISAT, refer to In-Situ Adaptive Tabulation (ISAT) in the Theory Guide). Each parallel node builds its own table, and there is no message passing to tables on other nodes. As some nodes may have more chemical reactions than others (for example one parallel node may contain just air at a constant temperature, in which case the ISAT table will contain only one entry and calculation will be rapid), there may be a load imbalance. The dynamic load balancing algorithm will migrate cells from high computational load nodes to low computational load nodes.

   If you decide to specify a value, this user-specified value is the ISAT proportion of the total computational effort.

f. You have the option of using model-weighted partitioning. The objective of model-weighted partitioning is to balance the overall number of cells, as well as the time needed for the selected models (that is, the enabled **Weight Types**, described previously). This is specifically useful for cases with models that could potentially lead to a load imbalance—for example, when using the discrete phase model, the distribution of particles could be different across partitions and may cause an imbalance, or in cases with large proportion of solid zones.

   Each model is considered as a constraint, and a base constraint is automatically introduced for the overall number of cells. When partitioning, ANSYS Fluent will automatically calculate the weights for these constraints, and balance each of them.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To enable model-weighted partitioning, ensure that the **Metis** partition method is selected, and enable the appropriate models under **Weight Types** in the **Weighting** tab. Then use the following text command prior to partitioning:

`parallel → partition → set → model-weighted-partition`

Note that you can get additional information specific to the constraints by setting the **Reporting Verbosity** to 2 in the **Options** tab.

7. When using the dynamic mesh model in your parallel simulations, the **Partition** dialog box includes an **Auto Repartition** option and a **Repartition Interval** setting. These parallel partitioning options are provided because ANSYS Fluent migrates cells when local remeshing and smoothing are performed. Therefore, the partition interface becomes very wrinkled and the load balance may deteriorate. By default, the **Auto Repartition** option is selected, where a percentage of interface faces and loads are automatically traced. When this option is selected, ANSYS Fluent automatically determines the most appropriate repartition interval based on various simulation parameters. Sometimes, using the **Auto Repartition** option provides insufficient results, therefore, the **Repartition Interval** setting can be used. The **Repartition Interval** setting lets you to specify the interval (in time steps or iterations respectively) when a repartition is enforced. When repartitioning is not desired, you can set the **Repartition Interval** to zero.

Important

Note that when dynamic meshes and local remeshing is utilized, updated meshes may be slightly different in parallel ANSYS Fluent (when compared to serial ANSYS Fluent or when compared to a parallel solution created with a different number of compute nodes), resulting in very small differences in the solutions.

---

8. Click the **Partition** button to partition the mesh.

9. If you decide that the new partitions are better than the previous ones (if the mesh was already partitioned), click the **Use Stored Partitions** button to make the newly stored cell partitions the active cell partitions. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file.

34.5.4.1.1. Example of Setting Selected Registers to Specified Partition IDs

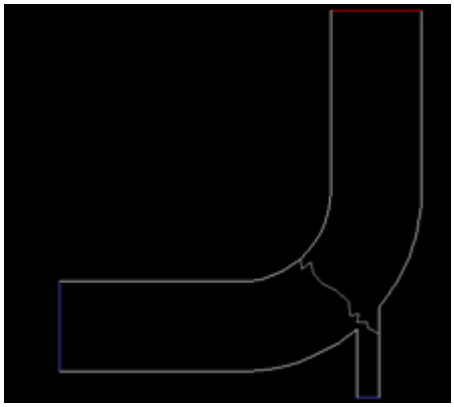
1. Start ANSYS Fluent in parallel. The case in this example was partitioned across two nodes.

2. Read in your case.

3. Display the mesh with the **Partitions** option enabled in the **Mesh Display** dialog box (Figure 34.11: The Partitioned Mesh (p. 2041)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 34.11: The Partitioned Mesh



4. Adapt your region and mark your cells (for details, see Performing Region Adaption (p. 1693)). This creates a register.

5. Open the **Partitioning and Load Balancing** dialog box.

6. Set the **Set Selected Zones and Registers to Partition ID** to `0` and click the corresponding button. This displays the following output in the ANSYS Fluent console:

```
>> 2 Active Partitions:
  ------------------------------------------------------------------------
  Collective Partition Statistics:      Minimum      Maximum   Total
  ------------------------------------------------------------------------
  Cell count                            459          459       918
  Mean cell count deviation             0.0%         0.0%
  Partition boundary cell count         11           11        22
  Partition boundary cell count ratio   2.4%         2.4%      2.4%

  Face count                            764         1714       2461
  Mean face count deviation             -38.3%       38.3%
  Partition boundary face count         13          13        17
  Partition boundary face count ratio   0.8%        1.7%      0.7%

  Partition neighbor count              1           1
  ------------------------------------------------------------------------
  Partition Method                      Metis
  Stored Partition Count                2
Done.
```

7. Click the **Use Stored Partitions** button to make the new partitions valid. This migrates the partitions to the compute-nodes. The following output is then displayed in the ANSYS Fluent console:

```
Migrating partitions to compute-nodes.
>> 2 Active Partitions:
     P   Cells  I-Cells  Cell Ratio   Faces  I-Faces  Face Ratio  Neighbors
     0     672      24        0.036    2085       29      0.014          1
     1     246      24        0.098     425       29      0.068          1
  ------------------------------------------------------------------------
  Collective Partition Statistics:     Minimum       Maximum      Total
  ------------------------------------------------------------------------
  Cell count                           246           672          918
  Mean cell count deviation            -46.4%        46.4%
  Partition boundary cell count        24            24           48
  Partition boundary cell count ratio  3.6%          9.8%         5.2%

  Face count                           425           2085         2461
  Mean face count deviation            -66.1%        66.1%
  Partition boundary face count        29            29           49
```

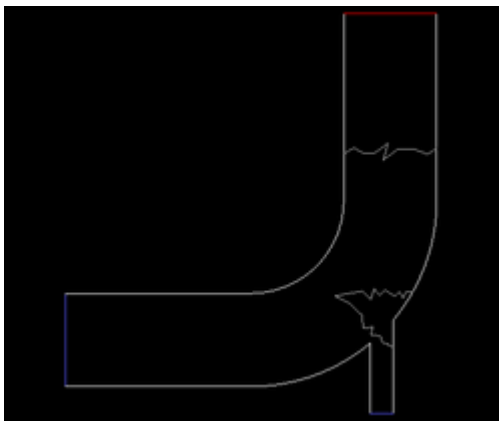
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  Partition boundary face count ratio  1.4%          6.8%         2.0%

  Partition neighbor count             1             1
  ------------------------------------------------------------------------
  Partition Method                     Metis
  Stored Partition Count               2
Done.
```

8. Display the mesh (Figure 34.12: The Partitioned ID Set to Zero (p. 2042)).

Figure 34.12: The Partitioned ID Set to Zero

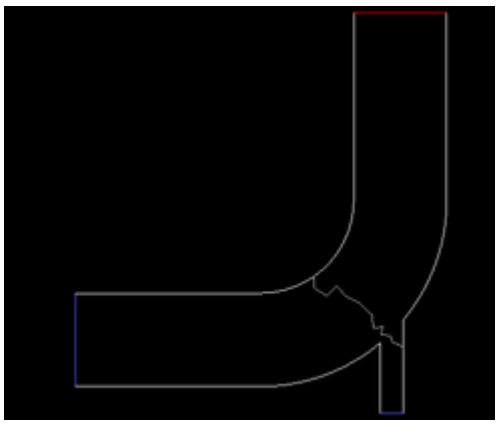


9. This time, set the **Set Selected Zones and Registers to Partition ID** to 1 and click the corresponding button. This displays a report in the ANSYS Fluent console.

10. Click the **Use Stored Partitions** button to make the new partitions valid and to migrate the partitions to the compute-nodes.

11. Display the mesh (Figure 34.13: The Partitioned ID Set to 1 (p. 2042)). Notice now that the partition appears in a different location as specified by your partition ID.

Figure 34.13: The Partitioned ID Set to 1



Important

Although this example demonstrates setting selected registers to specific partition IDs in parallel, it can be similarly applied in serial.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.5.4.1.2. Partitioning Within Zones or Registers

The ability to restrict partitioning to cell zones or registers gives you the flexibility to apply different partitioning strategies to subregions of a domain. For example, if your geometry consists of a cylindrical plenum connected to a rectangular duct, you may want to partition the plenum using the **Cylindrical Axes** method, and the duct using the **Cartesian Axes** method.

If the plenum and the duct are contained in two different cell zones, you can select one at a time and perform the desired partitioning, as described in Using the Partitioning and Load Balancing Dialog Box (p. 2033). If they are not in two different cell zones, you can create a cell register (basically a list of cells) for each region using the functions that are used to mark cells for adaption. These functions allow you to mark cells based on physical location, cell volume, gradient or isovalue of a particular variable, and other parameters. See Adapting the Mesh (p. 1681) for information about marking cells for adaption. Manipulating Adaption Registers (p. 1701) provides information about manipulating different registers to create new ones. Once you have created a register, you can partition within it as described in Example of Setting Selected Registers to Specified Partition IDs (p. 2040).

Important

Note that partitioning within zones or registers is not available when **Metis** is selected as the partition **Method**.

For dynamic mesh applications, ANSYS Fluent stores the partition method used to partition the respective zone. Therefore, if repartitioning is done, ANSYS Fluent uses the same method that was used to partition the mesh.

34.5.4.1.3. Reporting During Partitioning

As the mesh is partitioned, information about the partitioning process will be displayed in the console. By default, the number of partitions created, the time required for the partitioning, and the minimum and maximum cell, face, interface, and face-ratio variations will be displayed (for details, see Interpreting Partition Statistics (p. 2052)). If you increase the **Reporting Verbosity** to 2 from the default value of 1, the partition method used, the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each partition will also be displayed in the console. If you decrease the **Reporting Verbosity** to 0, only the number of partitions created and the time required for the partitioning will be reported.

You can request a portion of this report to be displayed again after the partitioning is completed. When you click the **Print Active Partitions** or **Print Stored Partitions** button in the parallel solver, ANSYS Fluent will display the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each active or stored partition in the console. In addition, it will display the minimum and maximum cell, face, interface, and face-ratio variations. In the serial solver, you will obtain the same information about the stored partition when you click **Print Partitions**. For details, see Interpreting Partition Statistics (p. 2052).

Important

Recall that to make the stored cell partitions the active cell partitions you must click the **Use Stored Partitions** button. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.5.4.1.4. Resetting the Partition Parameters

If you change your mind about your partition parameter settings, you can easily return to the default settings assigned by ANSYS Fluent by clicking on the **Default** button. When you click the **Default** button, it will become the **Reset** button. The **Reset** button allows you to return to the most recently saved settings (that is, the values that were set before you clicked on **Default**). After execution, the **Reset** button will become the **Default** button again.

34.5.4.2. Load Balancing

A dynamic load balancing capability is available in ANSYS Fluent. The principal reason for using parallel processing is to reduce the turnaround time of your simulation, which may be achieved by the following means:

- Faster machines, for example, faster CPU, memory, cache, and communication bandwidth between the CPU and memory
- Faster interconnects, for example, smaller latency and larger bandwidth
- Better Load balancing, for example, load is evenly distributed and CPUs are not idled during calculation

The first two evolve at the pace of computer technology, which is beyond the scope of this document. The third item is regarding optimization of available computation power. Here we are mainly talking about load balancing on dedicated homogeneous resources, which is often the case nowadays. If you are not using a dedicated homogeneous resource, you may need to account for differences in CPU speeds during partitioning by specifying a load distribution (for details, see Load Distribution (p. 2055)).

On a dedicated homogeneous system, the key for load balancing is how to evaluate the computational requirement of each cell. By default, ANSYS Fluent assumes that each cell requires the same computational work, but this is often not the case. For example

- A hexahedral cell demands more CPU and memory than a tetrahedral cell.
- A cell with particle tracking will use more time than a cell without particle tracking.
- ISAT species model cells may have magnitude differences in time usage.

To balance these differences, ideally, the time used in each cell could be recorded and load balance achieved based on these detailed timing statistics. However, this can be expensive and such low level timings can be unreliable in any case. Instead, we identify features causing computational imbalance and record time usage for these models in aggregate. For a more detailed description of this, refer to Partitioning (p. 2033) in the discussion of the **Weighting** tab. In addition, the imbalance may happen dynamically during run time, for example

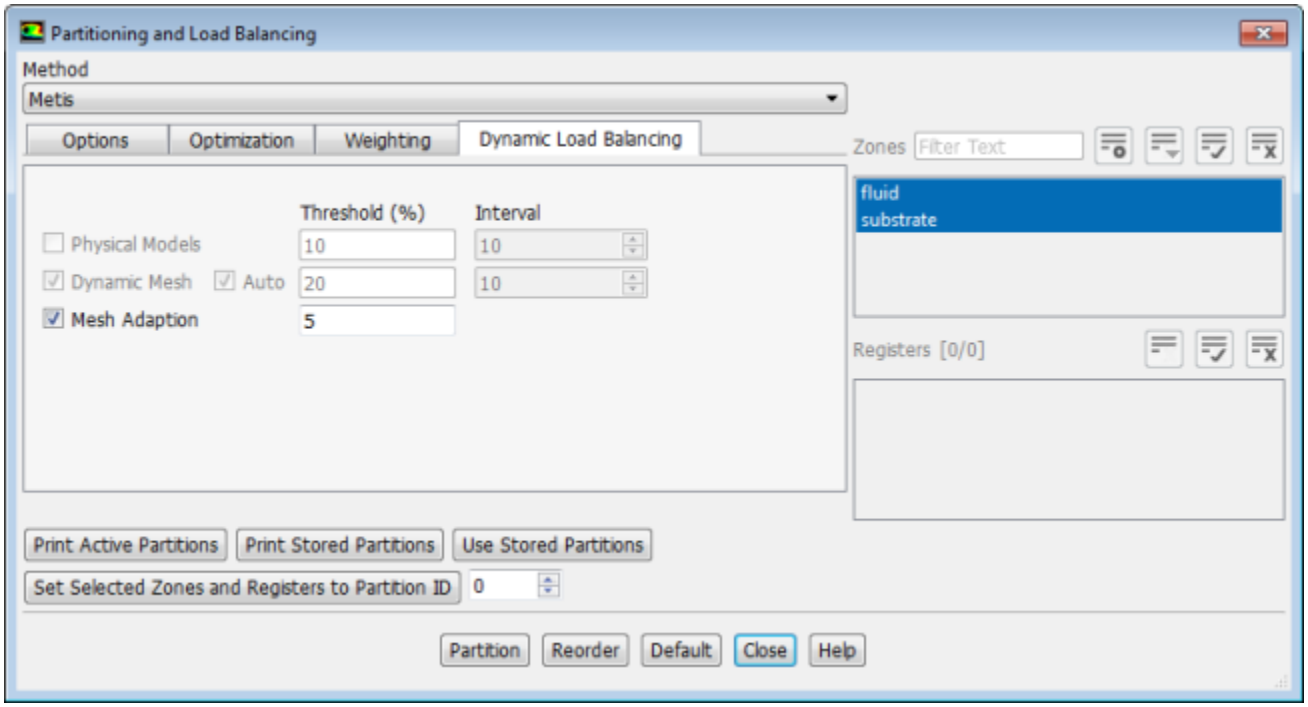
- The mesh may be changed by adaption or mesh movement.
- In unsteady cases, particle tracking may move from one region to another region.

Dynamic load balancing has been implemented for better scalability of cases with imbalanced physical or geometrical models, thereby reducing the simulation time. The implementation considers weights from these models scaled by CPU time usage. Load balancing for DPM, VOF, cell type (number of faces per cell), and solid zones can be performed. In addition, cell weight based load balancing and machine load distribution can also be specified (for details, see Load Distribution (p. 2055)). ANSYS Fluent takes the weights from physical models and considers them for partitioning. The weights are assembled based

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

on the time used by each physical model. For dynamic load balancing, the load is checked and balanced based on your specified imbalance threshold. To apply dynamic load balancing on the various models, click the **Dynamic Load Balancing** tab and select the required balancing as follows:

Figure 34.14: The Dynamic Load Balancing Tab



1. Enable **Physical Models** load balancing during iterations so that the load will be evaluated for time usage and weight distribution, based on the **Interval** that you provide. If the imbalance exceeds the specified **Threshold**, then repartitioning will be performed by considering the selected weights. **Physical Models** load balancing will only be available when you have the specific physical models enabled in the case. You will be prompted to enable the weights for those models. When weights for the physical models are all disabled, you will be prompted to disable **Physical Models** load balancing.

   Note

   Applying load balancing too frequently may cause performance degradation due to the additional cost of migrating cells for the new partition layout.

2. Enable **Dynamic Mesh** if there is any dynamic mesh movement. Load balancing, based on the number of cells, will be checked and balanced if the imbalance threshold is exceeded. These parallel partitioning options are provided because with mesh motion, when local remeshing and smoothing are performed, the partition interface can become very wrinkled and load balance may deteriorate. By default, the **Auto** option is selected, where a percentage of interface faces and loads are automatically traced. When this option is selected, ANSYS Fluent automatically determines the most appropriate repartitioning interval based on various simulation parameters. However, sometimes, the frequency of load balancing from the **Auto** option may be inadequate, and then the **Interval** setting can be explicitly set. The **Interval** setting lets you specify the interval (in time steps or iterations, respectively) when load balancing is enforced. When load balancing is

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

not desired, you may disable **Dynamic Mesh** load balancing. Dynamic Mesh load balancing is only available when you have dynamic models enabled in your case.

Important

Note that when dynamic meshes and local remeshing are utilized, updated meshes may be slightly different in parallel ANSYS Fluent (when compared to serial ANSYS Fluent or when compared to a parallel solution created with a different number of compute nodes), resulting in very small differences in the solutions.

---

3. Enable **Mesh Adaption**. Any time mesh adaption occurs, load balancing, based on the number of cells, will be checked and balanced if the imbalance threshold is exceeded. If problems arise in your computations due to adaption, you can disable the load balancing for **Mesh Adaption**.

34.5.5. Mesh Partitioning Methods

Partitioning the mesh for parallel processing has three major goals:

- Create partitions with equal numbers of cells.
- Minimize the number of partition interfaces — that is, decrease partition boundary surface area.
- Minimize the number of partition neighbors.

Balancing the partitions (equalizing the number of cells) ensures that each processor has an equal load and that the partitions will be ready to communicate at about the same time. Since communication between partitions can be a relatively time-consuming process, minimizing the number of interfaces can reduce the time associated with this data interchange. Minimizing the number of partition neighbors reduces the chances for network and routing contentions. In addition, minimizing partition neighbors is important on machines where the cost of initiating message passing is expensive compared to the cost of sending longer messages. This is especially true for workstations connected in a network.

The partitioning schemes in ANSYS Fluent use bisection or METIS algorithms to create the partitions, but unlike other schemes that require the number of partitions to be a factor of two, these schemes have no limitations on the number of partitions. You will create as many partitions as there are computing units (cores based on processors and machines) available for your simulation.

34.5.5.1. Partition Methods

The mesh is partitioned using a bisection or METIS algorithm. The selected algorithm is applied to the parent domain, and then recursively applied to the subdomains. For example, to divide the mesh into four partitions with a bisection method, Fluent will bisect the entire (parent) domain into two child domains, and then repeat the bisection for each of the child domains, yielding four partitions in total. To divide the mesh into three partitions with a bisection method, Fluent will "bisect" the parent domain to create two partitions—one approximately twice as large as the other—and then bisect the larger child domain again to create three partitions in total. METIS uses graph partitioning techniques that generally provide more optimal partitions than the geometric methods.

The mesh can be partitioned using one of the algorithms listed below. The most efficient choice is problem-dependent, so you can try different methods until you find the one that is best for your problem. See Guidelines for Partitioning the Mesh (p. 2033) for recommended partitioning strategies.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cartesian Axes
bisects the domain based on the Cartesian coordinates of the cells (see Figure 34.15: Partitions Created with the Cartesian Axes Method (p. 2048)). It bisects the parent domain and all subsequent child subdomains perpendicular to the coordinate direction with the longest extent of the active domain. It is often referred to as coordinate bisection.

Cartesian Strip
uses coordinate bisection but restricts all bisections to the Cartesian direction of longest extent of the parent domain (see Figure 34.16: Partitions Created with the Cartesian Strip or Cartesian X-Coordinate Method (p. 2049)). You can often minimize the number of partition neighbors using this approach.

Cartesian X-, Y-, Z-Coordinate
bisects the domain based on the selected Cartesian coordinate. It bisects the parent domain and all subsequent child subdomains perpendicular to the specified coordinate direction. (See Figure 34.16: Partitions Created with the Cartesian Strip or Cartesian X-Coordinate Method (p. 2049).)

Cartesian R Axes
bisects the domain based on the shortest radial distance from the cell centers to that Cartesian axis (x, y, or z) whichever produces the smallest interface size. This method is available only in 3D.

Cartesian RX-, RY-, RZ-Coordinate
bisects the domain based on the shortest radial distance from the cell centers to the selected Cartesian axis (x, y, or z). These methods are available only in 3D.

Cylindrical Axes
bisects the domain based on the cylindrical coordinates of the cells. This method is available only in 3D.

Cylindrical R-, Theta-, Z-Coordinate
bisects the domain based on the selected cylindrical coordinate. These methods are available only in 3D.

Metis
uses the METIS software package for partitioning irregular graphs, developed by Karypis and Kumar at the University of Minnesota and the Army HPC Research Center. It uses a multilevel approach in which the vertices and edges on the fine graph are coalesced to form a coarse graph. The coarse graph is partitioned, and then uncoarsened back to the original graph. During coarsening and uncoarsening, algorithms are applied to permit high-quality partitions. Detailed information about METIS can be found in its manual [49] (p. 2889).

Important

If you create non-conformal interfaces, and generate virtual polygonal faces, your METIS partition can cross non-conformal interfaces by using the connectivity of the virtual polygonal faces. This improves load balancing for the parallel solver and minimizes communication by decreasing the number of partition interface cells.

Polar Axes
bisects the domain based on the polar coordinates of the cells (see Figure 34.19: Partitions Created with the Polar Axes or Polar Theta-Coordinate Method (p. 2050)). This method is available only in 2D.

Polar R-Coordinate, Polar Theta-Coordinate
bisects the domain based on the selected polar coordinate (see Figure 34.19: Partitions Created with the Polar Axes or Polar Theta-Coordinate Method (p. 2050)). These methods are available only in 2D.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Principal Axes

bisects the domain based on a coordinate frame aligned with the principal axes of the domain (see Figure 34.17: Partitions Created with the Principal Axes Method (p. 2049)). This reduces to Cartesian bisection when the principal axes are aligned with the Cartesian axes. The algorithm is also referred to as moment, inertial, or moment-of-inertia partitioning.

This is the default bisection method in ANSYS Fluent.

Principal Strip

uses moment bisection but restricts all bisections to the principal axis of longest extent of the parent domain (see Figure 34.18: Partitions Created with the Principal Strip or Principal X-Coordinate Method (p. 2050)). You can often minimize the number of partition neighbors using this approach.

Principal X-, Y-, Z-Coordinate

bisects the domain based on the selected principal coordinate (see Figure 34.18: Partitions Created with the Principal Strip or Principal X-Coordinate Method (p. 2050)).

Spherical Axes

bisects the domain based on the spherical coordinates of the cells. This method is available only in 3D.

Spherical Rho-, Theta-, Phi-Coordinate

bisects the domain based on the selected spherical coordinate. These methods are available only in 3D.

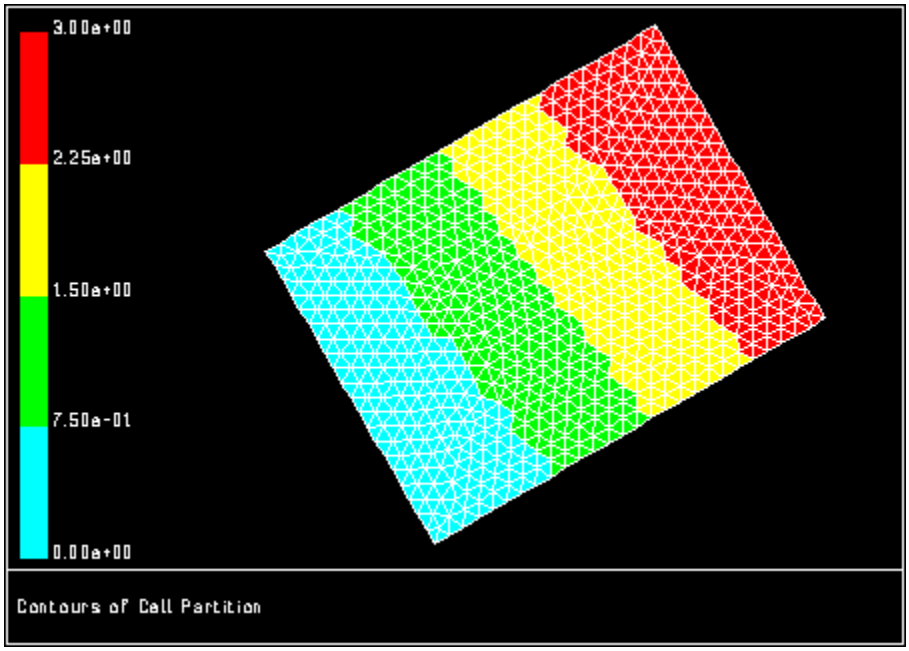

Figure 34.19: Partitions Created with the Polar Axes or Polar Theta-Coordinate Method

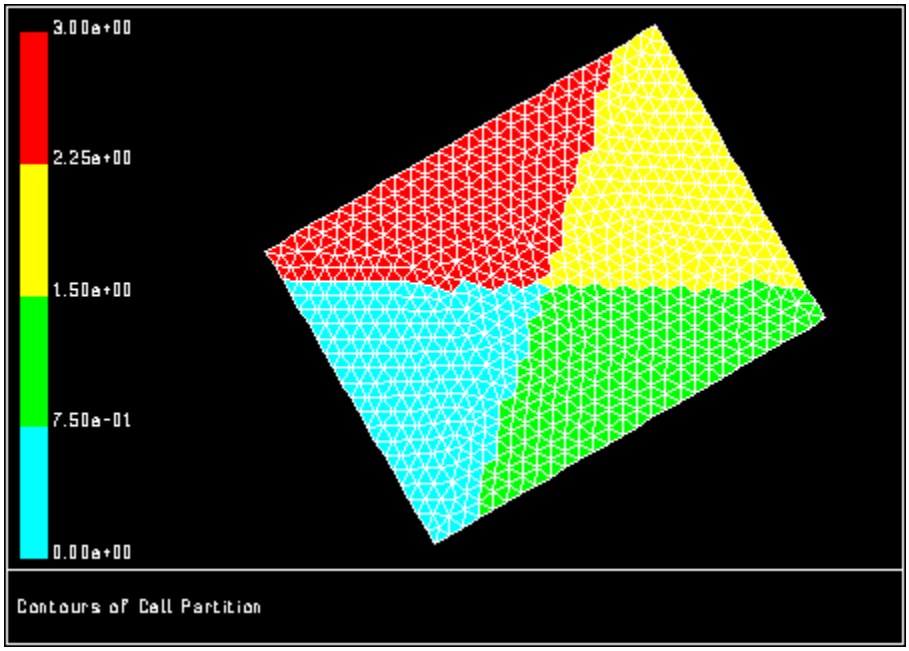

34.5.5.2. Optimizations

Additional optimizations can be applied to improve the quality of the mesh partitions. The heuristic of bisecting perpendicular to the direction of longest domain extent is not always the best choice for creating the smallest interface boundary. A pre-testing operation (for details, see Pretesting (p. 2051)) can be applied to automatically choose the best direction before partitioning. In addition, the following iterative optimization schemes exist:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Smooth

attempts to minimize the number of partition interfaces by swapping cells between partitions. The scheme traverses the partition boundary and gives cells to the neighboring partition if the interface boundary surface area is decreased. (See Figure 34.20: The Smooth Optimization Scheme (p. 2051).)

Merge

attempts to eliminate orphan clusters from each partition. An orphan cluster is a group of cells with the common feature that each cell within the group has at least one face that coincides with an interface boundary. (See Figure 34.21: The Merge Optimization Scheme (p. 2051).) Orphan clusters can degrade multigrid performance and lead to large communication costs.

Figure 34.20: The Smooth Optimization Scheme

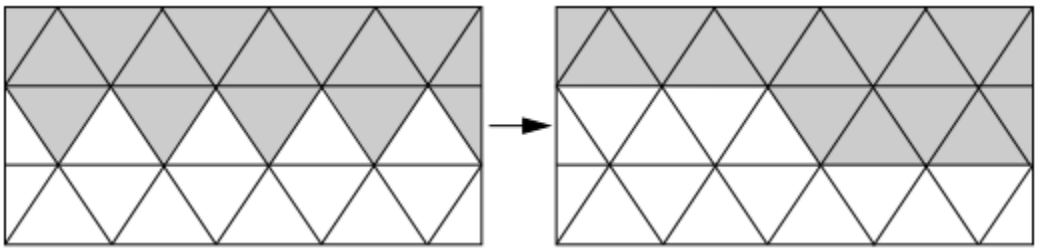

Figure 34.21: The Merge Optimization Scheme

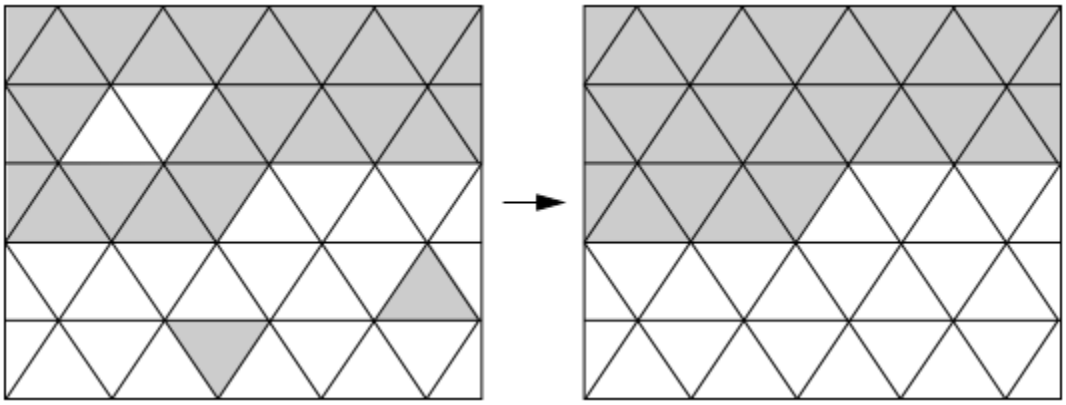


In general, the Smooth and Merge schemes are relatively inexpensive optimization tools.

34.5.5.3. Pretesting

If you choose the **Principal Axes** or **Cartesian Axes** method, you can improve the bisection by testing different directions before performing the actual bisection. If you choose not to use pretesting (the default), ANSYS Fluent will perform the bisection perpendicular to the direction of longest domain extent.

If pretesting is enabled, it will occur automatically when you click the **Partition** button in the Partitioning and Load Balancing Dialog Box (p. 2767), or when you read in the mesh if you are using automatic partitioning. The bisection algorithm will test all coordinate directions and choose the one which yields the fewest partition interfaces for the final bisection.

Note that using pretesting will increase the time required for partitioning. For 2D problems partitioning will take 3 times longer than without pretesting, and for 3D problems it will take 4 times longer.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.5.5.4. Using the Partition Filter

As noted above, you can use the METIS partitioning method through a filter in addition to within the **Auto Partition Mesh** and **Partitioning and Load Balancing** dialog boxes. To perform METIS partitioning on an unpartitioned mesh, use the **File/Import/Partition/Metis...** ribbon tab item.

File → Import → Partition → Metis...

ANSYS Fluent will use the METIS partitioner to partition the mesh, and then read the partitioned mesh. The number of partitions will be equal to the number of processes. You can then proceed with the model definition and solution.

Important

Direct import to the parallel solver through the partition filter requires that the host machine has enough memory to run the filter for the specified mesh. If not, you must run the filter on a machine that does have enough memory. You can either start the parallel solver on the machine with enough memory and repeat the process described above, or run the filter manually on the new machine and then read the partitioned mesh into the parallel solver on the host machine.

To manually partition a mesh using the partition filter, enter the following command:

`utility partition` *input_filename partition_count output_filename*

where *input_filename* is the filename for the mesh to be partitioned, *partition_count* is the number of partitions desired, and *output_filename* is the filename for the partitioned mesh. You can then read the partitioned mesh into Fluent (using the standard **File/Read/Case...** ribbon tab item) and proceed with the model definition and solution.

When the **File/Import/Partition/Metis...** ribbon tab item is used to import an unpartitioned mesh into the parallel solver, the METIS partitioner partitions the entire mesh. You may also partition each cell zone individually, using the **File/Import/Partition/Metis Zone...** ribbon tab item.

File → Import → Partition → Metis Zone...

This method can be useful for balancing the work load. For example, if a case has a fluid zone and a solid zone, the computation in the fluid zone is more expensive than in the solid zone, so partitioning each zone individually will result in a more balanced work load.

34.5.6. Checking the Partitions

After partitioning a mesh, you should check the partition information and examine the partitions graphically.

34.5.6.1. Interpreting Partition Statistics

You can request a report to be displayed after partitioning (either automatic or manual) is completed. In the parallel solver, click the **Print Active Partitions** or **Print Stored Partitions** button in the **Partitioning and Load Balancing** dialog box. In the serial solver, click the **Print Partitions** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ANSYS Fluent distinguishes between two cell partition schemes within a parallel problem: the active cell partitions and the stored cell partitions. Initially, both are set to the cell partitions that were established upon reading the case file. If you re-partition the mesh using the **Partitioning and Load Balancing** dialog box, the new partitions will be referred to as the stored cell partitions. To make them the active cell partitions, you must click the **Use Stored Partitions** button in the **Partitioning and Load Balancing** dialog box. The active cell partitions are used for the current calculation, while the stored cell partitions (determined from the last partitioning performed) are used when you save a case file. This distinction is made mainly to allow you to partition a case on one machine or network of machines and solve it on a different one. Thanks to the two separate partitioning schemes, you could use the parallel solver with a certain number of compute nodes to subdivide a mesh into an arbitrary different number of partitions, suitable for a different parallel machine, save the case file, and then load it into the designated machine.

When you click **Print Partitions** in the serial solver, you will obtain information about the stored partitions.

The output generated when you print the partitions consists of tabulated information about the active or stored partitioning scheme. A typical output for a mesh with 4 partitions is as follows:

```
 >> 4 Active Partitions:
     P   Cells I-Cells Cell Ratio   Faces I-Faces Face Ratio Neighbors Load
     0    3520     142      0.040   11399     195      0.017         1    1
     1    3298     115      0.035   10678     151      0.014         1    1
     2    3451     305      0.088   11404     372      0.033         2    1
     3    3583     332      0.093   11586     416      0.036         2    1

    ------------------------------------------------------------------------
    Collective Partition Statistics:        Minimum   Maximum   Total
    ------------------------------------------------------------------------
    Cell count                              3298      3583      13852
    Mean cell count deviation               -4.8%     3.5%
    Partition boundary cell count           115       332       894
    Partition boundary cell count ratio     3.5%      9.3%      6.5%

    Face count                              10678     11586     44500
    Mean face count deviation               -5.2%     2.8%
    Partition boundary face count           151       416       567
    Partition boundary face count ratio     1.4%      3.6%      1.3%

    Partition neighbor count                1         2
    ------------------------------------------------------------------------
    Partition Method                        Metis
    Stored Partition Count                  4
```

The first table in the output displays per-partition statistics of interest:

P
the partition ID

Cells
the number of cells in the partition

I-Cells
the number of interface cells in the partition (that is, cells that lie on the partition interfaces)

Cell Ratio
the ratio of interface cells to total cells for the partition

Faces
the number of faces in the partition

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

I-Faces
the number of interface faces in the partition (that is, faces that lie on partition interfaces)

Face Ratio
the ratio of interface faces to total faces for the partition

Neighbors
the number of neighbor partitions

Load
the desired relative load on this node in proportion to the other nodes. See Load Distribution (p. 2055) for details.

Note that partition IDs correspond directly to compute node IDs when a case file is read into the parallel solver. When the number of partitions in a case file is larger than the number of compute nodes, but is evenly divisible by the number of compute nodes, then the distribution is such that partitions with IDs 0 to $\left(M-1\right)$ are mapped onto compute node 0, partitions with IDs M to $\left(2M-1\right)$ onto compute node 1, and so on, where M is equal to the ratio of the number of partitions to the number of compute nodes.

The second table in the output displays `Minimum`, `Maximum`, and (where applicable) `Total` values for various partition statistics:

Cell Count
the number of cells in the partitions (corresponding to `Cells` in the per-partition table)

Mean cell count deviation
the deviation of an individual partition cell count from the mean partition cell count

Partition boundary cell count
the number of cells that lie on partition interfaces (corresponding to `I-Cells` in the per-partition table)

Partition boundary cell count ratio
the ratio of the number of cells that lie on partition interfaces to the total number of cells in the partition (corresponding to `Cell Ratio` in the per-partition table)

Face Count
the number of faces in the partitions (corresponding to `Faces` in the per-partition table)

Mean face count deviation
the deviation of an individual partition face count from the mean partition face count

Partition boundary face count
the number of faces that lie on partition interfaces (corresponding to `I-Faces` in the per-partition table)

Partition boundary face count ratio
the ratio of the number of faces that lie on partition interfaces to the total number of faces in the partition (corresponding to `Face Ratio` in the per-partition table)

Partition neighbor count
the number of neighbors for a given partition (corresponding to `Neighbors` in the per-partition table)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Finally, the `Partition Method` and `Stored Partition Count` are displayed.

Your aim is to achieve small magnitudes for `Minimum`, `Maximum`, and `Total` values of the `Partition boundary face count ratio` while maintaining a balanced load (`Mean cell count variation`).

If there is an overset mesh for which the solution has been initialized, an additional partition table with solve and dead cells is included in the partitioning report (see Overset Cell Marks (p. 191) for the definitions of such cells):

```
 >> Overset partition statistics:
     P   Cells Solve-cells Dead-cells  Ext donors
     0      66          53          4          12
     1      66          55          4          10

    ------------------------------------------------------------------------
    Overset Partition Statistics:           Minimum   Maximum   Total
    ------------------------------------------------------------------------
    Cell count                              66        66        132
    Mean cell count deviation               0.0%      0.0%

    Solve cell count                        53        55        108
    Mean solve cell count deviation         -1.9%     1.9%

    Dead cell count                         4         4         8
    Mean dead cell count deviation          0.0%      0.0%

    Ext donors                              10        12        22
    ------------------------------------------------------------------------
    Partition Method                        Metis
    Stored Partition Count                  2
```

34.5.6.2. Examining Partitions Graphically

To further aid interpretation of the partition information, you can draw contours of the mesh partitions (see the figures in Partition Methods (p. 2046)).

Results → Graphics → Contours Edit...

To display the active cell partition or the stored cell partition (which were described above), select **Active Cell Partition** or **Stored Cell Partition** in the **Cell Info...** category of the **Contours Of** drop-down list, and turn off the display of **Node Values** (for details, see Displaying Contours and Profiles (p. 1756) for information about displaying contours).

Important

If you have not already done so in the setup of your problem, you must perform a solution initialization in order to use the **Contours** dialog box.

34.5.7. Load Distribution

If the speeds of the processors that will be used for a parallel calculation differ significantly, you can specify a load distribution for partitioning, using the `load-distribution` text command.

`parallel → partition → set → load-distribution`

For example, if you will be solving on three compute nodes, and one machine is twice as fast as the other two, then you may want to assign twice as many cells to the first machine as to the others (that is, a load vector of (2 1 1)). During subsequent mesh partitioning, partition 0 will end up with twice as many cells as partitions 1 and 2.

For this example, you need to start up ANSYS Fluent such that compute node 0 is the fast machine, since partition 0, with twice as many cells as the others, will be mapped onto compute node 0. Alternatively, in this situation, you could enable the load balancing feature (described in Load Balancing (p. 2044)) to have ANSYS Fluent automatically attempt to discern any difference in load among the compute nodes.

34.5.8. Troubleshooting

When running a calculation using parallel ANSYS Fluent, you may encounter a warning message in the console that reports problems related to the partitioning. The following is an example of such a warning:

```
#AMG# Warning: The global matrix size (1273286) is too large, and may
adversely affect the parallel performance. See the ANSYS Fluent User's
Guide for information on troubleshooting partitioning issues.
```

The following are possible reasons for partitioning problems, along with recommendations for reducing them:

- The presence of solid zones may cause a partition to have a very small amount of fluid cells. For such cases, it is recommended that you partition the mesh with the **Across Zones** option disabled in the **Partitioning and Load Balancing** dialog box, and then click the **Use Stored Partitions** button.
- A partition may have a small number of cells if you have set up a load distribution for partitioning. Such settings should be disabled, by using the `load-distribution` text command (described in Load Distribution (p. 2055)) and entering a value of `1` for each of the previously defined partitions.
- Some model settings (for example, shell conduction) can encapsulate some cells, which may cause difficulties with the coarsening process. To remedy this situation, you can either try a different partitioning method, or you can enable the global coarsening checking criteria with the following rpvar setting:

  ```
  (rpsetvar 'amg/parallel/global-check-coarsening? #t)
  ```

- Coupled walls are encapsulated as part of the shell conduction model and S2S model. If you have partitioning problems, you can try reverting to the encapsulation routine used prior to version 16.0 by disabling the enhanced encapsulation:

  `define` → `models` → `shell-conduction` → `enhanced-encapsulation?`

34.6. Using General Purpose Graphics Processing Units (GPGPUs) With the Algebraic Multigrid (AMG) Solver

You can accelerate the Algebraic Multigrid (AMG) solver inside Fluent using General Purpose Graphics Processing Units (GPGPUs) if suitable hardware is available on your compute machines. When enabled, you can use GPGPU acceleration for AMG computations in a parallel Fluent session on linear systems with up to 5 coupled equations. Using GPGPUs requires HPC licenses. Licensing details can be found in HPC Licensing in the *ANSYS, Inc. Licensing Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.6.1. Requirements

The following GPGPUs are supported:

- For Windows:
  - NVIDIA Tesla K40m
  - NVIDIA Tesla M2075
- For Linux:
  - NVIDIA Tesla K20xm
  - NVIDIA Tesla K40m
  - NVIDIA Tesla K80

The following requirements must be satisfied in order to use this functionality:

- The pressure-based coupled solver must be selected.
- CUDA 6.0 and the required driver must be installed.

In addition, when starting the parallel Fluent session the following conditions must be met:

- The number of solver processes per machine must be equal on all machines.
- The number solver processes per machine must be evenly divisible by the specified number of GPGPUs per machine.

34.6.2. Limitations

GPGPU acceleration is subject to the following limitations:

- When using Fluent in Workbench, the number of GPGPUs cannot be set through:
  - Properties of Setup Cells
  - Properties of Solution Cells
  - Properties of Solution Cells through RSM update
  - Properties of Parameter Sets through RSM update
- GPGPU acceleration will not be used in the following cases:
  - The population balance model is active.
  - The Eulerian multiphase model is active.
  - The system has more than 5 coupled equations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.6.3. Using and Managing GPGPUs

In order to use GPGPUs, you must specify in the Fluent Launcher or with the `-gpgpu=` *ngpgpus* command line option how many GPGPUs are to be used per machine. For details, refer to the following sections:

Starting Parallel ANSYS Fluent Using Fluent Launcher (p. 2012)
Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options (p. 2021)
Starting Parallel ANSYS Fluent on a Linux System (p. 2026)

Once the Fluent session is running, you can view and/or select the available GPGPUs on the system using the following TUI commands:

`parallel/gpgpu/show`
display the available GPGPUs on the system.

`parallel/gpgpu/select`
select the GPGPUs to use. Note that you can only select up to the number of GPGPUs that you specified on the command line or in the Fluent Launcher when starting the session.

By default, GPGPU acceleration is applied automatically to coupled systems and not to scalar systems because scalar systems typically are not as computationally expensive. However, if desired you can enable/disable GPGPU acceleration of the AMG solver for coupled and scalar systems in the following TUI menu:

```
solve/set/amg-options/amg-gpgpu-options/
```

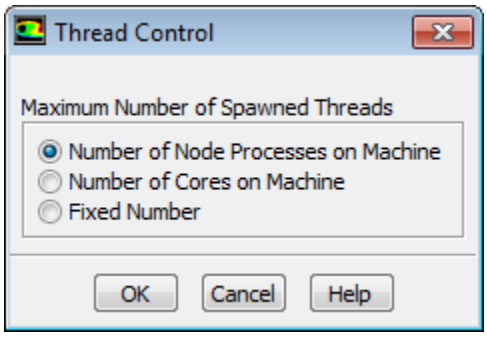
The menu contains commands for each supported equation type allowing you to enable/disable GPGPU acceleration, choose between AMG and FGMRES solvers, and specify various solver options.

34.7. Controlling the Threads

You can control the maximum number of threads on each machine by using the **Thread Control** dialog box (Figure 34.23: The Parallel Connectivity Dialog Box (p. 2059)).

Parallel → General → Thread Control...

Figure 34.22: The Thread Control Dialog Box



You have the following options when using the **Thread Control** dialog box:

- **Number of Node Processes on Machine**

  This is the default option. When this option is chosen, the maximum number of threads on each machine is equal to the number of ANSYS Fluent node processes on each machine.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Number of Cores on Machine**

  When this option is chosen, the maximum number of threads on each machine is equal to the number of cores on the machine. ANSYS Fluent obtains the number of cores from the OS. This may be applicable when the multi-threaded part of the calculation is dominating the computation time, and the continuous phase calculation is relatively small, and you want to take full advantage of the computation resources. For example, if you have a very small case with regard to the number of cells, but a large number of particles to be tracked, you may want to spawn one ANSYS Fluent node process on each machine, but use the maximum number of cores in order to get a good overall performance.

- **Fixed Number**

  When this option is chosen, you may specify the maximum number of threads that can be spawned on each machine in the number-entry box below **Fixed Number**. This may only be applicable when you want to have fine control of the number of threads on each machine; it is not recommended in general.

34.8. Checking Network Connectivity

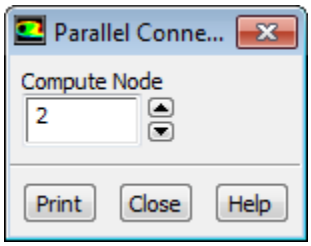
For any compute node, you can print network connectivity information that includes the hostname, architecture, process ID, and ID of the selected compute node and all machines connected to it. The ID of the selected compute node is marked with an asterisk.

The ID for the ANSYS Fluent host process is always `host`. The compute nodes are numbered sequentially starting from `node-0`. All compute nodes are completely connected. In addition, compute node 0 is connected to the host process.

To obtain connectivity information for a compute node, you can use the Parallel Connectivity Dialog Box (p. 2760) (Figure 34.23: The Parallel Connectivity Dialog Box (p. 2059)).

Parallel → Network → Connectivity...

Figure 34.23: The Parallel Connectivity Dialog Box



Indicate the compute node ID for which connectivity information is desired in the **Compute Node** field, and then click the **Print** button. Sample output for compute node 0 is shown below:

```
------------------------------------------------------------------------------------------
ID      Hostname              Core        O.S.        PID     Vendor
------------------------------------------------------------------------------------------
n5      host25                2/64        Linux-64    18909   AMD Opteron(tm) 6278
n2      host25                1/64        Linux-64    18908   AMD Opteron(tm) 6278
n4      host24                2/64        Linux-64    32939   AMD Opteron(tm) 6278
n1      host24                1/64        Linux-64    32938   AMD Opteron(tm) 6278
host    host23                -           Linux-64    38427   AMD Opteron(tm) 6278
n3      host23                2/64        Linux-64    38755   AMD Opteron(tm) 6278
n0*     host23                1/64        Linux-64    38754   AMD Opteron(tm) 6278
```

34.9. Checking and Improving Parallel Performance

Fluent offers several tools to help you optimize the performance of your parallel computations. You can check the utilization of your hardware using the parallel check feature. To determine how well the parallel solver is working, you can measure computation and communication times, and the overall parallel efficiency, using the performance meter. You can also control the amount of communication between compute nodes in order to optimize the parallel solver, and take advantage of the automatic load balancing feature of ANSYS Fluent.

Information about checking and improving parallel performance is provided in the following sections:

34.9.1. Parallel Check
34.9.2. Checking Parallel Performance
34.9.3. Optimizing the Parallel Solver
34.9.4. Clearing the Linux File Cache Buffers

34.9.1. Parallel Check

You can use the **Check** command in the **Parallel** ribbon tab to check various factors that affect parallel performance. Checks are performed to identify the following issues:

- CPU cores are overloaded
- CPU clock is throttled
- System memory usage is too high
- A faster interconnect is available
- Partitions are imbalanced (if a valid mesh is loaded)

34.9.2. Checking Parallel Performance

The performance meter allows you to report the wall clock time elapsed during a computation, as well as message-passing statistics. Since the performance meter is always enabled, you can access the statistics by displaying them after the computation is completed. To view the current statistics, click **Usage** in the **Parallel** ribbon tab (**Timer** group box).

Parallel → **Timer** → **Usage**

Performance statistics will be displayed in the console.

To clear the performance meter so that you can eliminate past statistics from the future report, click **Reset** in the **Parallel** ribbon tab (**Timer** group box).

Parallel → **Timer** → **Reset**

The following example demonstrates how the current parallel statistics are displayed in the console:

```
Performance Timer for 1 iterations on 4 compute nodes
Average wall-clock time per iteration:           4.901 sec
Global reductions per iteration:                   408 ops
Global reductions time per iteration:            0.000 sec (0.0%)
Message count per iteration:                       801 messages
Data transfer per iteration:                     9.585 MB
LE solves per iteration:                           12 solves
LE wall-clock time per iteration:                2.445 sec (49.9%)
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  LE global solves per iteration:                    27 solves
  LE global wall-clock time per iteration:        0.246 sec (5.0%)
  AMG cycles per iteration:                          64 cycles
  Relaxation sweeps per iteration:                 4160 sweeps
  Relaxation exchanges per iteration:               920 exchanges

  Total wall-clock time:                          4.901 sec
```

A description of the parallel statistics is as follows:

- `Average wall-clock time per iteration` describes the average real (wall clock) time per iteration.
- `Global reductions per iteration` describes the number of global reduction operations (such as variable summations over all processes). This requires communication among all processes.

  A global reduction is a collective operation over all processes for the given job that reduces a vector quantity (the length given by the number of processes or nodes) to a scalar quantity (for example, taking the sum or maximum of a particular quantity). The number of global reductions cannot be calculated from any other readily known quantities. The number is generally dependent on the algorithm being used and the problem being solved.
- `Global reductions time per iteration` describes the time per iteration for the global reduction operations.
- `Message count per iteration` describes the number of messages sent between all processes per iteration. This is important with regard to communication latency, especially on high-latency interconnects.

  A message is defined as a single point-to-point, send-and-receive operation between any two processes. This excludes global, collective operations such as global reductions. In terms of domain decomposition, a message is passed from the process governing one subdomain to a process governing another (usually adjacent) subdomain.

  The message count per iteration is usually dependent on the algorithm being used and the problem being solved. The message count and the number of messages that are reported are totals for all processors.

  The message count provides some insight into the impact of communication latency on parallel performance. A higher message count indicates that the parallel performance may be more adversely affected if a high-latency interconnect is being used. Ethernet has a higher latency than Myrinet or Infiniband. Therefore, a high message count will more adversely affect performance with Ethernet than with Infiniband.

  To check the latency of the overall cluster interconnect, refer to Checking Latency and Bandwidth (p. 2062).
- `Data transfer per iteration` describes the amount of data communicated between processors per iteration. This is important with respect to interconnect bandwidth.

  Data transfer per iteration is usually dependent on the algorithm being used and the problem being solved. This number generally increases with increases in problem size, number of partitions, and physics complexity.

  The data transfer per iteration may provide some insight into the impact of communication bandwidth (speed) on parallel performance. The precise impact is often difficult to quantify because it is dependent on many things including: ratio of data transfer to calculations, and ratio of communication bandwidth to CPU speed. The unit of data transfer is a byte.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To check the bandwidth of the overall cluster interconnect, refer to Checking Latency and Bandwidth (p. 2062).

- `LE solves per iteration` describes the number of linear systems being solved per iteration. This number is dependent on the physics (non-reacting versus reacting flow) and the algorithms (pressure-based versus density-based solver), but is independent of mesh size. For the pressure-based solver, this is usually the number of transport equations being solved (mass, momentum, energy, and so on).
- `LE wall-clock time per iteration` describes the time (wall-clock) spent doing linear equation solvers (that is, multigrid).
- `LE global solves per iteration` describes the number of solutions on the coarsest level of the AMG solver where the entire linear system has been pushed to a single processor (`n0`). The system is pushed to a single processor to reduce the computation time during the solution on that level. Scaling generally is not adversely affected because the number of unknowns is small on the coarser levels.
- `LE global wall-clock time per iteration` describes the time (wall-clock) per iteration for the linear equation global solutions.
- `AMG cycles per iteration` describes the average number of multigrid cycles (V, W, flexible, and so on) per iteration.
- `Relaxation sweeps per iteration` describes the number of relaxation sweeps (or iterative solutions) on all levels for all equations per iteration. A relaxation sweep is usually one iteration of Gauss-Siedel or ILU.
- `Relaxation exchanges per iteration` describes the number of solution communications between processors during the relaxation process in AMG. This number may be less than the number of sweeps because of shifting the linear system on coarser levels to a single node/process.
- `Time-step updates per iteration` describes the number of sub-iterations on the time step per iteration.
- `Time-step wall-clock time per iteration` describes the time per sub-iteration.
- `Total wall-clock time` describes the total wall-clock time.

The most relevant quantity is the `Total wall clock time`. This quantity can be used to gauge the parallel performance (speedup and efficiency) by comparing this quantity to that from the serial analysis (the command line should contain `-t1` in order to obtain the statistics from a serial analysis).

34.9.2.1. Checking Latency and Bandwidth

You can check the latency and bandwidth of the overall cluster interconnect, to help identify any issues affecting ANSYS Fluent scalability, by clicking **Latency** and **Bandwidth** in the **Parallel** ribbon tab (**Network** group box).

Parallel → Network → Latency

Depending on the number of machines and processors being used, a table containing information about the communication speed for each node will be displayed in the console. The table will also summarize the minimum and maximum latency between two nodes.

Consider the following example when checking for latency:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Latency (usec) with 1000 samples [1.83128 sec]
 ----------------------------------------
 ID       n0     n1     n2    n3    n4    n5
 ----------------------------------------
 n0            48.0   48.2  48.2  48.3   *50
 n1    48.0           48.2  48.3  48.3   *48
 n2    48.2    48.2         48.8  49.1   *53
 n3    48.2    48.3    *49        48.6  48.5
 n4    48.3    48.3   49.1  48.6         *50
 n5    49.7    48.5    *53  48.5  49.7

 ----------------------------------------
 Min: 47.9956 [n0<-->n1]
 Max: 52.6836 [n5<-->n2]
 ----------------------------------------
```

Important

In the above table, (*) is the maximum value in that row. The smaller the latency, the better.

Six processors (n0 to n5) are spawned. The latency between n0 and n1 is 48.0 μs. Similarly, the latency between n1 and n2 is 48.2 μs. The minimum latency occurs between n0 and n1 and the maximum latency occurs between n2 and n5, as noted in the table. Checking the latency is particularly useful when you are not seeing expected speedup on a cluster.

Parallel → Network → Bandwidth

In addition to checking for latency, you can check your bandwidth. A table containing information about the amount of data communicated within one second between two nodes is displayed in the console. The table will also summarize the minimum and maximum bandwidth between two nodes.

Consider the following example when checking for bandwidth:

```
Bandwidth (MB/s) with 5 messages of size 4MB [4.36388 sec]
 ----------------------------------------
 ID      n0     n1     n2     n3     n4     n5
 ----------------------------------------
 n0          111.8    *55  111.8   97.5  101.3
 n1   111.8          69.2   98.7  111.7    *51
 n2    54.7   69.2          72.9  104.8    *45
 n3   111.8   98.7   72.9          64.0    *45
 n4    97.6  111.7  104.8    *64          76.9
 n5   101.2   50.9   45.5    *45    76.9

 ----------------------------------------
 Min: 45.1039 [n5<-->n3]
 Max: 111.847 [n0<-->n3]
 ----------------------------------------
```

Important

In the above table, (*) is the minimum value in that row. The larger the bandwidth, the better.

The bandwidth between n0 and n1 is 111.8 MB/s. Similarly, the bandwidth between n1 and n2 is 69.2 MB/s. The minimum amount of bandwidth occurs between n3 and n5 and the maximum occurs between n0 and n3, as noted in the table. Checking the bandwidth is particularly useful when you cannot see good scalability with relatively large cases.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

34.9.3. Optimizing the Parallel Solver

34.9.3.1. Increasing the Report Interval

In ANSYS Fluent, you can reduce communication and improve parallel performance by increasing the report interval for residual printing/plotting or other solution monitoring reports. You can modify the value for **Reporting Interval** in the Run Calculation Task Page (p. 2537).

Solution → Run Calculation Calculate...

Important

Note that you will be unable to interrupt iterations until the end of each report interval.

34.9.3.2. Accelerating View Factor Calculations for General Purpose Computing on Graphics Processing Units (GPGPUs)

View factor computations can be accelerated through the `viewfac_acc` utility that uses a combination of MPI/OpenMP/OpenCL models to speed up view factor computations. Irrespective of the number of MPI processes launched, only one MPI process/machine is used for computing view factors. On each machine, one MPI process spawns several OpenMP threads that actually compute the view factors. Since only one MPI process is required per machine, it is recommended that you start just one MPI process per machine and specify the number of OpenMP threads to use when running the utility outside of ANSYS Fluent. With fewer MPI processes, the system memory usage is reduced as well. When running the utility from inside ANSYS Fluent, the number of `viewfac_acc` processes will be same as the number of ANSYS Fluent processes. If OpenCL-capable GPUs are available, then a portion of the view factor computations are done on GPUs using OpenCL, to further speed up the computation. At present, this capability is limited to the hemicube method with the cluster-to-cluster option on lnamd64 and win64 machines.

When using the utility `viewfac_acc` outside of ANSYS Fluent, you can specify the following command line options:

- `-cpu` # (default = -2) The number of OpenMP threads to launch per machine.
  - -2: The number of MPI processes.
  - -1: The total number of logical CPU cores.
  - 0: No CPU used.
  - n: Up to maximum n.
- `-gpu` # (default = 1) The number of GPU devices to use per machine.
  - –1: The total number of GPU devices.
  - 0: No GPU used.
  - n: Up to maximum n.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `-gpu_cpu_ratio` # (default = 2.0) The ratio of the work load on 1 GPU vs 1 CPU OpenMP thread. This is based on the time consumed by the GPU and the CPU. At the end of the view factor computations, a recommendation is printed for the GPU/CPU work load ratio to use in future computations.

When using the `viewfac_acc` utility from inside an ANSYS Fluent session, use the `/define/models/radiation/s2s-parameters/compute-clusters-and-vf-accelerated` text interface (TUI) command. You will only be prompted for the `-gpu` and `-gpu_cpu_ratio` options (as described previously) and not the `-cpu` option, as the number of OpenMP threads to launch per machine can be specified in the Thread Control Dialog Box (p. 2811) (see Controlling the Threads (p. 2058) for details).

In order to use the GPU for view factor computations, the OpenCL library should be accessible through the appropriate environment variable (`LD_LIBRARY_PATH` on lnamd64 or `%path%` on win64). By default on lnamd64, `/usr/lib64` is searched, but if the library is installed in another location, then that location should be specified in the `LD_LIBRARY_PATH` variable.

View factor computations can also be accelerated through the `raytracing_acc` utility that uses the NVIDIA Optix library for tracing the rays. The GPU available on the machine running the host process is used in such a scenario, except in a mixed Windows-Linux simulation where the GPU on node-0 is used. An NVIDIA GPU along with CUDA 6.0 is required for using `raytracing_acc`. At present, this utility is available only on lnamd64 (Red Hat Enterprise Linux 5/6, and SUSE Linux Enterprise Server 11) and win64 (Windows 7) machines for 3D problems. In order to use the utility, the CUDA 6.0 library should be accessible through the appropriate environment variable (`LD_LIBRARY_PATH` on lnamd64 or `%path%` on win64).

When using the `raytracing_acc` utility from outside an ANSYS Fluent session, the command line is `utility raytracing_acc <input_cluster_file> [output_s2s_file(optional)]`.

When using the `raytracing_acc` utility from inside an ANSYS Fluent session, use the `/define/models/radiation/s2s-parameters/compute-clusters-and-vf-accelerated` text user interface (TUI) command.

34.9.3.3. Accelerating Discrete Ordinates (DO) Radiation Calculations

An accelerated discrete ordinate (DO) radiation solver is available on Linux when running a parallel Fluent session. While it is computationally faster than the standard DO solver, it may take a larger number of iterations to converge.

After you have selected the DO model in the **Radiation Model** dialog box, you can enable the accelerated DO solver by using the following text command:

`define` → `models` → `radiation` → `do-acceleration?`

If NVIDIA GPGPUs are enabled in the Fluent session, this solver will accelerate the DO computations by using the GPGPUs. In the absence of GPGPUs, this solver can still be used with the CPU cores to accelerate the DO computations. Note that the accelerated DO solver uses the first-order upwind scheme and an explicit relaxation of 1.0.

The accelerated DO solver is incompatible with some models and settings; when necessary, Fluent will automatically revert to the standard DO solver when the calculation is started and print a message about the conflict.

If you plan to use GPGPUs with the accelerated DO solver, it is recommended that you run NVIDIA's multi-process server (MPS) before launching ANSYS Fluent using the following command: `nvidia-`

`cuda-mps-control -d`. It is known to improve the robustness and performance of the GPGPU computations with the multiple Fluent processes.

34.9.4. Clearing the Linux File Cache Buffers

Processing performance can significantly decrease when the file cache buffers of a Linux machine are full. While this is true in serial, it is more often a concern when solving large cases in parallel, particularly when using AMD processors. If you see a performance decrease even though the case / machine setup has not changed, that is an indication that the file cache buffers may be to blame.

The filling of the file cache buffers can happen over a period of time as a result of input-output activity. Even after the ANSYS Fluent session is exited, by default the operating system does not free up the file cache buffers immediately (unless the operating system is unable to satisfy a malloc subroutine request with available free memory). During memory allocation for a parallel case, this can result in the allocation of memory from a different NUMA domain, and consequently can have a significant impact on performance.

To resolve this issue on Linux machines, you must first ensure that all of the relevant machines are idle (so that you do not adversely affect any jobs that are running). Then you can clear the file cache buffers by performing one of the following actions:

- Include the `-cflush` option when launching ANSYS Fluent from the command line.

  This option ensures that the file cache buffers are flushed in a separate operation. While this process may take a few minutes to complete (depending on the total memory of the system), it does not require you to have root privileges.

or

- Enter the `(drop-cache)` Scheme command (either in the ANSYS Fluent console or through your journal file) after launching Fluent but before you read the case file.

  This command will instantaneously clear the pagecaches, dentries, and inodes.

  Important

  Note that in order to use the `(drop-cache)` command, you must have sudo administrative privileges for the `/sbin/sysctl vm.drop_caches=3` command.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 35: Design Analysis and Optimization

In this chapter, the setup and use of the adjoint solver and the mesh morpher/optimizer in ANSYS Fluent are described. Both tools offer shape optimization capabilities, but the scope is complementary. The fundamental difference in the technology is that the adjoint solver uses gradient-based optimization by calculating derivatives, whereas the mesh morpher/optimizer uses a strategy that is not based on gradients to decide design updates.

The tools have a common approach to change a design by morphing the computational mesh. This has the benefit that you need not return to the original geometry in order to update the design for the purposes of the optimization.

The two key considerations when deciding whether to use the adjoint solver or the mesh morpher/optimizer are as follows:

- Is the flow physics / observable of interest supported by the adjoint solver? (For details about adjoint capabilities, see the following sections: Basic Assumptions and Consistency Checks (p. 2082) and General Observables (p. 2069)) If not, then the mesh morpher/optimizer is the better option, since there are very few limitations in the supported physics and choice of quantity of interest with this approach. It is important to verify that the quantity of interest can be specified as an adjoint solver observable.

- Is the dimension of the design space high? Detailed shape optimization of 3D geometries can involve design spaces with large dimensions (thousands of degrees of freedom or more). The adjoint solver is very effective in this scenario, whereas the use of the mesh morpher/optimizer becomes computationally prohibitive when the number of degrees of freedom exceeds more than, say, 10–20.

Details are provided in the following sections:

35.1. The Adjoint Solver
35.2. Using the Adjoint Solver
35.3. The Mesh Morpher/Optimizer
35.4. Using the Mesh Morpher/Optimizer

Note that the Fluent Tutorial Guide presents a tutorial that uses the adjoint solver. (To access tutorials and their input files on the ANSYS Customer Portal, go to http://support.ansys.com/training.)

35.1. The Adjoint Solver

An adjoint solver is a specialized tool that extends the scope of the analysis provided by a conventional flow solver by providing detailed sensitivity data for the performance of a fluid system.

In order to perform a simulation using the ANSYS Fluent standard flow solvers, a user supplies system geometry in the form of a computational mesh, specifies material properties and physics models, and configures boundary conditions of various types. The conventional flow solver, once converged, provides a detailed data set that describes the flow state governed by the flow physics that are being modeled. Various postprocessing steps can be taken to assess the performance of the system.

If a change is made to any of the data that defines the problem, then the results of the calculation can change. The degree to which the solution changes depends on how sensitive the flow is to the partic-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ular parameter that is being adjusted. Indeed, the derivative of the solution data with respect to that parameter quantifies this sensitivity to first order. Determining these derivatives is the domain of *sensitivity analysis*.

There is a large collection of derivative data that can be computed for a fluid system, given the extensive set of input data that is required, and the extensive flow data that is produced. The matrix of derivatives of output data with respect to input data can be vast. Depending upon the goal of the analysis only a portion of this derivative data may be needed for engineering analysis and decision-making.

The adjoint solver accomplishes the remarkable feat of calculating the derivative of a single engineering observation with respect to a very large number of input parameters simultaneously via a *single computation*. The engineering observation could be a measure of the system performance, such as the lift or drag on an airfoil, or the total pressure drop through a system. Most importantly, the derivatives with respect to the geometric shape of the system are found.

Understanding such sensitivities in a fluid system can provide extremely valuable engineering insight. A system that is highly sensitive may exhibit strong variability in performance due to small variations in manufacturing or variations in the environment in which it is operating. Alternatively, high-sensitivity may be leveraged for fluid control, with a small actuator being able to induce strong variations in behavior. Yet another perspective is that sensitivity of a performance measure implies that the device in question is not fully optimized and there is still room for improvement—assuming that constraints do not preclude further gains.

The sensitivities of a fluid system provided by an adjoint solver satisfy a central need in gradient-based shape optimization. This makes an adjoint solver a unique and powerful engineering tool for design optimization.

Adjoint data can also play a role in improving solver numerics. Regions of high sensitivity are indicative of areas in the flow where discretization errors can potentially have a strong effect. This information can be used to guide how best to refine a mesh to improve flow solution accuracy.

The process of computing an adjoint solution resembles that for a standard flow calculation in many respects. The adjoint solver solution advancement method is specified, residual monitors configured, and the solver is initialized and run through a sequence of iterations to convergence. One notable difference is that a scalar-valued observation is selected as being of interest prior to starting the adjoint calculation.

Once the adjoint solution is converged the derivative of the observable with respect to the position of each and every point on the surface of the geometry is available, and the sensitivity of the observation to specific boundary condition settings can be found. This remarkable feature of adjoint solutions has been known for hundreds of years, but only in the last 25 years has the significance for computational physics analysis been recognized widely.

The power of this methodology is highlighted when an alternative for assembling the same information is considered. Imagine a sequence of flow calculations in which each point on an airfoil surface is moved in turn a set small distance in the surface-normal direction, and the flow and drag recomputed. If there are N points on the surface, then N flow calculations are required to build the data set. Considering that the same data is provided by a *single* adjoint computation, the adjoint approach has an enormous advantage. Remember that for even modest 3D flow computations there may be many thousands of coordinates or more on a surface.

Once the adjoint is computed it can be used to guide intelligent design modifications to a system. After all, the adjoint sensitivity data provides a map across the entire surface of the geometry of the effect of moving the surface. Design modifications can be most effective if made in regions of high sensitivity

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

since small changes will have a large effect upon the engineering quantity of interest. This principle of making changes to a system in proportion to the local sensitivity is the foundation for the simple gradient algorithm for design optimization.

Once a candidate change in shape or other boundary condition has been selected, the effect of that change can be estimated using the computed derivative data. This amounts to a first order extrapolation using a Taylor series expansion around the baseline flow state. Clearly if a modification is chosen that is large enough that nonlinear effects become important then the accuracy of the predicted change cannot be guaranteed.

35.1.1. General Observables

Several observables are available and serve as the foundation for specifying the quantity that is of interest for the computation. Basic quantities such as forces and moments can be defined and each is given a name. The following types of observables are available:

- Force: the aerodynamic force in a specified direction on one or more walls.
- Moment of force: the aerodynamic moment about a specified moment center and moment axis. The integration is made over a specified collection of wall zones. Note that in 2D, the moment axis is normal to the plane of the flow.
- Swirl: the moment of the mass flow (with velocity $\underline{u}$) relative to an axis defined by a point, $\underline{r_c}$, and a direction $\underline{d}$. The two options are:
  - Swirl integral

$$\int_V \rho(\underline{r}\times\underline{u})\cdot\underline{d}dV \tag{35.1}$$

    where V denotes the volume over which the integration is made, and $\underline{r}$ denotes the relative position to the point $\underline{r_c}$.

  - Normalized swirl integral

$$\frac{\int_V \rho(\underline{r}\times\underline{u})\cdot\underline{d}dV}{\int_V \rho(\underline{r}\times(\underline{d}\times\underline{r}))\cdot\underline{d}dV} \tag{35.2}$$

    Note

    These integrals can be used to construct quantities such as tumble ratio that are of significance for internal combustion engine analysis.

- pressure drop between an inlet (or group of inlets) and an outlet (or group of outlets)

  The total pressure is computed by area-weighted averaging of the total pressure values on selected surfaces.
- fixed value: a simple fixed value can be specified and used in the assembly of the observables. This is convenient when some scaling or normalization of the observable is desired. It must be noted that this value is treated strictly as a constant for the purposes of any derivative calculations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- surface integral: a variety of surface integrals can be constructed for a specified field variable on a set of user-selected surfaces:

  – Facet sum: a simple sum of the field value on each facet of the computational mesh

  $$\sum_f \varphi_f \tag{35.3}$$

  – Facet average: the facet sum is divided by the total number of facets, N_f

  $$\overline{\varphi} = \frac{\sum_f \varphi_f}{N_f} \tag{35.4}$$

  – Facet variance: the sum of the squares of the deviations from the facet average

  $$\frac{\sum_f (\varphi_f - \overline{\varphi})^2}{N_f} \tag{35.5}$$

  – Integral: the sum of the field value on each face multiplied by the face area

  $$\sum_f \left|\underline{A}_f\right| \varphi_f \tag{35.6}$$

  – Area-weighted average: the integral divided by the total face area

  $$\frac{\sum_f \left|\underline{A}_f\right| \varphi_f}{\sum_f \left|\underline{A}_f\right|} \tag{35.7}$$

  – Area-weighted variance: the sum of the squares of the deviations from the area-weighted average, divided by the total face area

  $$\frac{\sum_f \left|\underline{A}_f\right| (\varphi_f - \overline{\varphi})^2}{\sum_f \left|\underline{A}_f\right|} \tag{35.8}$$

  – Mass-weighted integral: the sum of the field value on each face, weighted by the magnitude of the local mass flow through the face.

  $$\sum_f \left|\rho \underline{u}_f \cdot \underline{A}_f\right| \varphi_f \tag{35.9}$$

  – Mass-weighted average integral: the mass-weighted integral divided by the sum of the magnitudes of the local mass flow rates through the faces on which the integral is defined.

  $$\frac{\sum_f \left|\rho \underline{u}_f \cdot \underline{A}_f\right| \varphi_f}{\sum_f \left|\rho \underline{u}_f \cdot \underline{A}_f\right|} \tag{35.10}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– Mass-weighted variance: the mass-weighted integral of the square of the deviation from the mass-weighted average, divided by the sum of the magnitudes of the local mass flow rates through the faces on which the integral is defined.

$$\frac{\sum_f |\rho \underline{u}_f \cdot \underline{A}_f| \left(\varphi_f - \overline{\varphi}\right)^2}{\sum_f |\rho \underline{u}_f \cdot \underline{A}_f|} \tag{35.11}$$

– Flow-rate weighted: the rate at which the field is convected through the defined surfaces.

$$\sum_f \left(\rho \underline{u}_f \cdot \underline{A}_f\right) \varphi_f \tag{35.12}$$

– The field variables that can be used are:

→ Pressure

→ Total pressure

→ Mass flow per unit area

→ Temperature (when adjoint energy is enabled)

→ Heat flux (when adjoint energy is enabled)

• volume integral: you can compute a variety of volume integrals of a chosen field variable.

– Volume: computes the total volume of the selected zones as a summation of the individual cell volumes.

$$\int dV = \sum_{i=1}^{n} |V_i| \tag{35.13}$$

– Sum: computes the sum of a chosen field variable over the selected zones.

$$\sum_{i=1}^{n} |\varphi_i| \tag{35.14}$$

– Volume Integral: is calculated by summing the product of cell volume and the selected field variable over the selected zones.

$$\int \varphi dV = \sum_{i=1}^{n} \varphi_i |V_i| \tag{35.15}$$

– Volume-Weighted Average: is computed by dividing the volume integral of a selected field variable (Equation 35.15 (p. 2071)) by the total volume of the selected zones.

$$\int \varphi dV = \frac{1}{V} \sum_{i=1}^{n} \varphi_i |V_i| \tag{35.16}$$

– Volume Variance: is the volume-weighted integral of the square of the deviation from the volume-weighted average (Equation 35.16 (p. 2071)), divided by the total volume of the selected zone.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\frac{\sum_{i=1}^{n}|V_i|\left(\varphi_i-\overline{\varphi}\right)^2}{\sum_{i=1}^{n}|V_i|} \tag{35.17}$$

– Mass Integral: is computed by summing the product of density, cell volume, and the chosen field variable.

$$\int \rho\varphi dV=\sum_{i=1}^{n}\rho_i\varphi_i|V_i| \tag{35.18}$$

– Mass: is computed by summing the product of cell density and cell volume.

$$\int \rho dV=\sum_{i=1}^{n}\rho_i|V_i| \tag{35.19}$$

– Mass-Weighted Average: is computed by dividing the Mass Integral of the chosen field variable (Equation 35.18 (p. 2072)) by the total Mass (Equation 35.19 (p. 2072))

$$\frac{\int \rho\varphi dV=\sum_{i=1}^{n}\rho_i\varphi_i|V_i|}{\int \rho dV=\sum_{i=1}^{n}\rho_i|V_i|} \tag{35.20}$$

– Mass Variance: is computed as the mass-weighted summation of the square of the deviation of the chosen field variable from its mass-weighted average (Equation 35.20 (p. 2072)) divided by the total mass (Equation 35.19 (p. 2072)).

$$\frac{\sum_{i=1}^{n}\rho_i|V_i|\left(\varphi_i-\overline{\varphi}\right)^2}{\sum_{i=1}^{n}\rho_i|V_i|} \tag{35.21}$$

The volume integrals listed above can be computed for the following field variables:

– Pressure

– Total Pressure

– Velocity

– Velocity Magnitude

– Vorticity

– Vorticity Magnitude

– Turbulence Production: $\frac{\partial u_i}{\partial x_j}\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}\right)$

35.1.2. General Operations

Several operations are available to combine observables in various ways, if needed, to make a wide variety of compound observables. The following operations are available:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ratio of two quantities
- product of two quantities
- linear combination of N quantities $q_0 \ldots q_{N-1}$, with constant coefficients $a_0 \ldots a_{N-1}$ raised to various powers $v_0 \ldots v_{N-1}$, plus a constant offset c.

$$c + \sum_{i=0}^{N-1} a_i q_i^{v_i} \tag{35.22}$$

- arithmetic average of N quantities $q_0 \ldots q_{N-1}$

$$\overline{q} = \frac{\sum_{i=0}^{N-1} q_i}{N} \tag{35.23}$$

- mean variance of N quantities

$$\frac{\sum_{i=0}^{N-1} (q_i - \overline{q})^2}{N} \tag{35.24}$$

- unary operation (sin, cosine, and so on) on observable value q:
  - $1/q$
  - $|q|$
  - $\sqrt{q}$
  - $\sin q$
  - $\cos q$
  - $\tan q$
  - $\sin^{-1} q$
  - $\cos^{-1} q$
  - $\tan^{-1} q$
  - $\ln q$
  - $\log 10\ q$

35.1.3. Discrete Versus Continuous Adjoint Solver

When an adjoint solver is developed there is a key design decision that is made regarding the implementation, namely whether to use a *continuous* or a *discrete* approach. Both approaches are intended to compute the same sensitivity data—however, the approaches are remarkably different.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

While a user of the adjoint solver may experience no particular difference in workflow for the two separate solver types, it is important to be aware that there are two primary classes of adjoint solver and the approach chosen can have implications for the accuracy of the results.

A *continuous adjoint solver* relies heavily on mathematical properties of the partial-differential equations that define the physics of the problem. In this case those equations are the Navier-Stokes equations. With this approach an adjoint partial differential equation set is formulated explicitly and is accompanied by adjoint boundary conditions that are also derived mathematically. Only after this derivation is complete can the adjoint partial differential equations be discretized and solved, often with extensive re-use of existing solver machinery. This class of solver was implemented by ANSYS Fluent as a research effort.

Such a solver has the benefit that it is decoupled largely from the original flow solver. They share only the fact that they are based on the Navier-Stokes equations. The process of discretizing and solving the partial differential equations in each case could in principle be very different indeed. While this flexibility may be appealing it can also be the downfall of the approach. Inconsistencies in modeling, discretization and solution approaches can pollute the sensitivity information significantly, especially for problems with wall functions and complex engineering configurations such as those of interest to ANSYS Fluent users.

The continuous adjoint approach can be effective for some classes of problems. However, until there is a significant advance in handling some key challenges, ANSYS Inc. has concluded that it is an unsuitable approach for meeting the needs of our broad client base for the classes of problems of interest to them.

A *discrete adjoint solver* is based not on the form of the partial differential equations governing the flow, but the particular discretized form of the equations used in the flow solver itself. The sensitivity of the discretized equations forms the basis for the sensitivity calculation. In this approach the adjoint solver is much more tightly tied to the specific implementation of the original flow solver. This has been observed to yield sensitivity data that provides valuable engineering guidance for the classes of problem of interest to ANSYS Fluent users, including problems with wall functions.

For the above reasons, the discrete adjoint approach has been adopted for the ANSYS Fluent adjoint solver.

35.1.4. Discrete Adjoint Solver Overview

As discussed in the previous section, a discrete adjoint approach to solving the adjoint problem has been adopted, since it is believed to provide the most useful engineering sensitivity data for the classes of problems of interest to ANSYS clients.

An adjoint method can be used to compute the derivative of an observation of interest for the fluid system with respect to all the user-specified parameters, *with any changes that arise in the flow variables themselves eliminated*. There are three key ingredients to consider when developing the method:

1. All of the user-specified inputs:

   - All values set by a user in the boundary condition panels for each boundary in the problem.
   - The computational mesh. More specifically the locations of the nodes of the mesh and how they define the edges, faces, and ultimately the cells used in the finite-volume computation. This includes both interior as well as boundary nodes.
   - Material properties.
   - Model parameters such as model coefficients for turbulence models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the settings that define the problem are being distinguished from settings that define how the solution advancement is to be performed to converge the problem. Only the former are of interest here. For the sake of clarity, let us denote the vector of all of the values in the list by $\underline{c}$. These are considered to be the control variables for the problem, that is, the variables that a user can set explicitly that affect the solution.

It is worth noting that the topological definition of the mesh is fixed—it is not considered to be a control variable here. The effect of collapsing cells or remeshing on the flow solution is not addressable without further development in view of the discrete changes that are implied. This topic is beyond the scope of the current document.

2. The governing equations for the fluid system:

   The main effort in a flow computation is in the determination of the flow state, namely the velocity, pressure, density and possibly other fluid-related variables. For a cell-centered finite-volume scheme, the flow state is defined at the cell centroids by a vector of real values. In the simplest case these values are the pressure and flow velocity components. Let the vector of the variables in the ν th cell be denoted here by $\underline{q}^{\nu}$.

   At convergence the flow variables satisfy

$$\mathcal{R}_i^{\mu}\left(\underline{q}^0,\underline{q}^1,\ldots,\underline{q}^{M-1};\underline{c}\right)=0,\ \mu=0,\ldots,M-1,\ i=0,\ldots,L-1 \tag{35.25}$$

   where M is the number of cells in the problem, and there are L conditions on each cell. This expression is a compact way of denoting conservation of mass and momentum and other constraints.

3. The engineering observation of interest:

   Let

$$\mathcal{J}\left(\underline{q}^0,\underline{q}^1,\ldots,\underline{q}^{M-1};\underline{c}\right) \tag{35.26}$$

   denote a scalar of interest that depends both on the flow state and perhaps directly on the control variables. It is assumed that the observable is differentiable with respect to both the flow and the controls. The inclusion of the control variables here is essential since in many cases the mesh geometry is included directly in the evaluation of the observable. For example, the evaluation of the force on a boundary involves the wall normal and face areas, which change when mesh nodes are moved.

The goal is to determine the sensitivity of the observation with respect to the user-specified control variables. What makes defining this relationship more challenging is the fact that changing the user inputs changes the flow, which indirectly changes the engineering observation. The adjoint method has a specific role in managing this chain of influences by providing a mechanism for eliminating the specific changes that happen in the flow whenever the inputs change.

If a variation δc_j is introduced into the control variables then a linearization of the governing equations (Equation 35.25 (p. 2075)) shows that the variations in the flow state δq_j^{ν} must satisfy

$$\frac{\partial R_i^{\mu}}{\partial q_j^{\nu}}\delta q_j^{\nu}=-\frac{\partial R_i^{\mu}}{\partial c_j}\Big|_q \delta c_j,\ \mu=0,\ldots,M-1,\quad i=0,\ldots,L-1. \tag{35.27}$$

where there is an implied summation over j and ν, and $\Big|_q$ denotes that the flow solution is held constant while the derivative is taken.

Meanwhile, if both the control variables and the flow state change, then the observation will change:

$$\delta \mathcal{J} = \frac{\partial \mathcal{J}}{\partial q_j^\nu} \delta q_j^\nu + \left. \frac{\partial \mathcal{J}}{\partial c_j} \right|_q \delta c_j. \tag{35.28}$$

The particular way in which the flow responds to the changes in the control variables can be computed using (Equation 35.27 (p. 2075)) only after specific changes, δc_j, have been chosen. It is prohibitive to consider solving (Equation 35.27 (p. 2075)) for more than a handful of prescribed changes δc_j because of the excessive computing time that would be needed. However, when redesigning the shape of parts of a system there may be pressure to explore a large number of candidate modifications. This conflict is reconciled by eliminating the variations of the flow solution from the expression (Equation 35.28 (p. 2076)) and producing an explicit relationship between changes in the control variables and the observation of interest.

This is accomplished by taking a weighted linear combination of the linearized governing equations (Equation 35.27 (p. 2075)) in a very particular way. A set of adjoint variables $\tilde{q}^\mu$ is introduced with a one-to-one correspondence with the governing equations (Equation 35.25 (p. 2075)). This results in a relationship

$$\left[\tilde{q}_i^\mu \frac{\partial R_i^\mu}{\partial q_j^\nu} \right] \delta q_j^\nu = - \tilde{q}_i^\mu \left. \frac{\partial R_i^\mu}{\partial c_j} \right|_q \delta c_j. \tag{35.29}$$

The term in square brackets on the left is now matched to the coefficient for the variation in the flow in (Equation 35.28 (p. 2076)) in order to define values for the adjoint variables:

$$\frac{\partial R_i^\mu}{\partial q_j^\nu} \tilde{q}_i^\mu = \frac{\partial \mathcal{J}}{\partial q_j^\nu}. \tag{35.30}$$

These are the discrete adjoint equations, and the solution of this system that is the primary goal for the adjoint solver. It is important to recognize that these equations have not been derived. They are defined in this way with a specific goal in mind—the elimination from (Equation 35.28 (p. 2076)) of the perturbations to the flow field as shown below:

$$\begin{aligned} \delta \mathcal{J} &= \frac{\partial \mathcal{J}}{\partial q_j^\nu} \delta q_j^\nu + \left. \frac{\partial \mathcal{J}}{\partial c_j} \right|_q \delta c_j \\ &= \tilde{q}_i^\mu \frac{\partial R_i^\mu}{\partial q_j^\nu} \delta q_j^\nu + \left. \frac{\partial \mathcal{J}}{\partial c_j} \right|_q \delta c_j \\ &= \left\{ \left. \frac{\partial \mathcal{J}}{\partial c_j} \right|_q - \tilde{q}_i^\mu \left. \frac{\partial R_i^\mu}{\partial c_j} \right|_q \right\} \delta c_j \end{aligned} \tag{35.31}$$

Note the use of Equation 35.29 (p. 2076) and Equation 35.30 (p. 2076) in the derivation of Equation 35.31 (p. 2076). The flow perturbation has now been eliminated from the expression, yielding a direct relation between the control variables and the observable of interest.

There are several important observations to be made about (Equation 35.30 (p. 2076)):

- The dimension of the problem to be solved is the same as the original flow problem, although the adjoint problem is linear.
- While the adjoint solution may be considered strictly as a vector of numeric values, experience with the continuous adjoint provides guidance on how the adjoint solution can be interpreted. The vector of weights associated with the components of the residual of the momentum equation in each cell is termed the *adjoint velocity*. The adjoint value associated with the residual of the continuity equation is termed the *adjoint pressure*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The right hand side is defined purely on the basis of the observable that is of interest.
- The matrix on the left hand side is the *transpose* of the Jacobian of the governing system of equations (Equation 35.25 (p. 2075)). This seemingly innocent transposition has a very dramatic impact on how the adjoint system is solved. This will be discussed below.
- The adjoint equations are defined by the current state of the flow, and the specific physics that is employed in the modeling. Each adjoint solution is specific to the flow state.

At first glance it appears that solving the adjoint problem may be straightforward. After all it simply involves setting-up and solving a linear (albeit large) system of equations. In practice both steps can represent a significant challenge, especially when the problem is large.

The evaluation of the residuals of the flow equations is an integral part of the pre-existing ANSYS Fluent flow solvers. However, it is necessary to compute the Jacobian of the system $\partial R_i^\mu / \partial q_j^\nu$ and then transpose it, or at the very least to be able to make a matrix-free transpose matrix-vector product with the adjoint solution. There are several technical approaches to accomplishing this task whose description goes beyond the scope of this document. Suffice to say that it is not trivial to encode this functionality, but that it has been done successfully here.

For the present implementation, a pre-conditioned iterative scheme, based on pseudo-time marching, is adopted to solve the adjoint system. The equations that define the advancement process can be written as

$$\left\{\frac{P_{i,j}^{\mu,\nu}}{CFL\Delta t}+L_{ij}^{\mu,\nu}\right\}\Delta\tilde{q}_i^\nu=\frac{\partial \mathcal{J}}{\partial q_j^\mu}-\frac{\partial R_i^\nu}{\partial q_j^\mu}\tilde{q}_i^\nu \tag{35.32}$$

where Δt is a local time step size based on the local flow conditions, CFL is a user-specified CFL number. The matrix $L_{ij}^{\mu,\nu}$ is a simplified form of the system Jacobian that is amenable to solution using the AMG linear solver that is the workhorse of the conventional flow solver. The preconditioning matrix $P_{i,j}^{\mu,\nu}$ is a diagonal matrix. Artificial compressibility is introduced on the adjoint continuity equation to aid in the relaxation of the adjoint pressure field.

The correction $\Delta\tilde{q}_i^\mu$ is under-relaxed and added to the adjoint solution $\tilde{q}_i^\mu$ and the process repeated until the right hand side is adequately small.

35.1.5. Adjoint Solver Stabilization

When applied to problems with large cell counts and complex geometry, adjoint solvers sometimes experience stability issues. These instabilities can be associated with small scale unsteadiness in the flow field and/or strong shear, and tend to be restricted to small and isolated regions of the flow domain. Despite the spatial localization of these instabilities, the linearity of the adjoint problem provides no intrinsic limit on their growth during solution advancement. Their presence, if not handled, can disrupt the entire adjoint calculation despite the problem occurring in sometimes just a few cells. A stabilized solution scheme will be required to obtain adjoint solutions for problems at high Reynolds number in which there is strong shear and/or complex geometry.

Three stabilization schemes are available in Fluent in order to overcome these stability difficulties when larger cases are being solved. The stabilization schemes are designed to intervene only when the standard advancement scheme is experiencing instability.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Spatial scheme

The spatial scheme operates by identifying parts of the domain where unstable growth is occurring and applying a more direct and stable solution procedure in those regions.

Modal scheme

The modal scheme involves a process of identifying the particular details of the unstable growth patterns or modes. These patterns are localized in space and they are used to split the solution into parts that have stable and unstable characteristics when advanced. The stable part is advanced as usual, while the algorithm is designed now to compensate for the unstable part so that the overall calculation is stabilized.

The emergence of the unstable patterns can happen at any time during the adjoint calculation and the total number of unstable patterns is case-dependent. Having 10 to 20 unstable modes present would not be considered unusual. Large cases may have many more. As a general trend, the most rapidly-growing unstable patterns appear often within a few iterations with more slowly-growing modes appearing later in the calculation. The unstable patterns are handled as they appear.

Dissipation scheme

The dissipation scheme provides stabilization for the solution advancement of the adjoint solution by introducing nonlinear damping strategically into the calculation domain. The strategy is intended to provide minimal intervention in order to damp the growth of instabilities that lead to adjoint solution divergence. A marker is tracked, based on the state of the adjoint solution, and damping is applied directly to the adjoint solution in regions where the marker becomes large.

Unlike the modal and spatial schemes, the dissipation scheme can affect the adjoint solution slightly. In general, the spatial order of the damping is chosen to be one order larger than the adjoint calculation order. This means that the formal order of accuracy of the adjoint solver is unaffected by the addition of the dissipation scheme. In practice, regions of intense dissipation can appear for some cases which may result in isolated spots and/or streaks in the solution on surfaces. However, the scale of these solution features is such that they are often easily smoothed during postprocessing to generate design changes.

Some additional computational overhead is associated with the stabilization schemes. In general, the dissipation scheme is the least resource-intensive of the three schemes.

For information about using the stabilization schemes, refer to Stabilized Scheme Settings (p. 2094).

35.1.6. Solution-Based Adaption

An adjoint solution provides guidance on where best to adapt a computational mesh in order to resolve quantities of engineering interest.

Once the governing equations for the system (Equation 35.25 (p. 2075)) have been converged there remains a discretization error, ε_i^μ, such that

$$\mathcal{R}_i^\mu\left(\underline{q}^0,\underline{q}^1,\ldots,\underline{q}^{M-1};\underline{c}\right)=\varepsilon_i^\mu,\ \mu=0,\ldots,M-1,\quad i=0,\ldots,L-1. \tag{35.33}$$

While specific estimates for this discretization error may be tricky to define, it is often estimated to be $O\left(h^p\right)$, where h is the local grid size, and p is the order of the discretization scheme. That is, $p=1$ for a first-order scheme and $p=2$ for a second order scheme. Alternatively, ε_i^μ can be considered to be the residual associated with a solution that is not converged fully.

The correction to the flow field, δq_j^ν, that compensates for this inhomogeneity is given by

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\frac{\partial R_i^\mu}{\partial q_j^\nu}\delta q_j^\nu = -\varepsilon_i^\mu \tag{35.34}$$

from which it follows quickly that

$$\delta \mathcal{J} = \frac{\partial \mathcal{J}}{\partial q_j^\nu}\delta q_j^\nu = -\varepsilon_i^\mu \tilde{q}_i^\mu . \tag{35.35}$$

This simple expression provides an estimate of the effect of the presence of ε_i^μ on the observation, $\mathcal{J}$.

The presence of discretization errors, or lack of convergence, on the engineering quantity of interest is assessed by weighting the inhomogeneous term by the local adjoint solution. It is clear that even in regions of the domain where the residuals or discretization errors are small, an accompanying adjoint velocity or pressure that is large in magnitude implies that there may be a significant source of error in the observable. A finer mesh in regions where the adjoint is large will reduce the influence of discretization errors that may adversely affect the engineering result of interest. In practice, adapting cells which have large magnitude adjoint velocity and/or adjoint pressure will achieve this goal.

35.1.7. Using The Data To Improve A Design

Adjoint sensitivity data can be used to guide how to modify a system in order to improve the performance. The observable of interest can be made larger or smaller, depending upon the engineering goal.

A common strategy for deciding how to modify the system is based on the gradient algorithm. The underlying principle is quite simply that modifying a system in a manner to which it is most sensitive maximizes the effect of the change. The change to a control variable is made in proportion to the sensitivity of the value of interest with respect to that control variable.

Denote the sensitivity of the cost with respect to shape by

$$\delta \mathcal{J} = \frac{\partial \mathcal{J}}{\partial x_j^n}\delta x_j^n \tag{35.36}$$

where x_j^n is the j^{th} coordinate of the n^{th} node in the mesh. Here x_j^n is a notation for the subset of the control variables c_j for the system that correspond to mesh node positions. Then an adjustment

$$\delta x_j^n = \lambda \frac{\partial \mathcal{J}}{\partial x_j^n} \tag{35.37}$$

will provide the maximum adjustment to $\mathcal{J}$ for given L^2 norm of δx_j^n, where λ is an arbitrary scaling factor. Note that λ can be picked to be positive or negative depending upon whether $\mathcal{J}$ is to be increased or decreased respectively. This is essentially a statement of the method of steepest descent.

Furthermore, the change is estimated to first order to be

$$\delta \mathcal{J} = \lambda \frac{\partial \mathcal{J}}{\partial x_j^n}\frac{\partial \mathcal{J}}{\partial x_j^n} . \tag{35.38}$$

For a sufficiently small adjustment, the change to the observation will strictly have the same sign as the scaling factor λ, provided the gradient is not identically zero.

In regions where the sensitivity is high, small adjustments to the shape will have a large effect on the observable. This corresponds directly with the idea of engineering robustness. If a configuration shows high sensitivities, then the performance will likely be subject to large performance variations if there

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are manufacturing inconsistencies. For a robust design, the goal is to have the sensitivity be tolerably small.

In practical cases the field $\partial \mathcal{J} / \partial x_j^\eta$ can be noisy, especially for large, turbulent flow problems. If the noisy field is used directly to modify a boundary shape using (Equation 35.37 (p. 2079)), then the modified surface can have many inflections. This is not helpful for engineering design work. In the next section, the use of mesh morphing technology not only to smooth the sensitivity field, but also to provide smooth boundary and interior mesh deformation, is described.

35.1.7.1. Smoothing and Mesh Morphing

As has been noted, for typical engineering problems, the shape sensitivity field can have smoothness properties that are not adequate to define a shape modification. Mesh morphing technology is used here for both two- and three-dimensional systems in a two-fold role. The first role is as a smoother for the surface sensitivity field. The second role is to provide smooth distortions not only of the boundary mesh, but also the interior mesh. This approach is very appealing since it functions for arbitrary mesh cell types.

Note

For simplicity, the smoothing and morphing equations are presented here for the case of a 2D domain. The same approach is extended and used for 3D problems.

A Cartesian or cylindrical region is defined such that it encompasses all or a part of the problem domain. Only the mesh nodes that fall within this region may move as a result of the morphing operation. A local (u,v) coordinate system is defined, where $u \in [0,1]$ and $v \in [0,1]$. A regular array of $N_u \times N_v$ control points is then distributed in the control volume. The motion of the mesh at any point in the domain is determined by the movement of the control points.

In general, an optimization problem may include both free-form minimization or maximization of the observable(s) and constraints that are localized in space. This requires an approach that can provide a deformation field that is well-behaved and consistent with manufacturability requirements, while still allowing locally sharper deformations where required to satisfy the imposed constraints.

To achieve this, two coincident sets of control points are created. Bernstein polynomials and B-splines are used, respectively, to map the control point motions to the computational mesh nodes.

The i^{th} Bernstein polynomial of degree ℓ is:

$$B_{i,\ell}(u) = \binom{\ell}{i} u^i (1-u)^{n-i} \tag{35.39}$$

The i^{th} B-spline of degree p is the non-periodic B-spline that uses a knot-vector, $\{t_i\}$, where:

$$t_i = \begin{cases} 0 & i \le p \\ (i-p)/(\ell-2p) & p < i < \ell - p \\ 1 & i \ge \ell - p \end{cases} \tag{35.40}$$

The value of the B-spline is defined recursively as:

$$S_{i,0}(t) = \begin{cases} 1 & t_i < t < t_{i+1}; t_i < t_{i+1} \\ 0 & \text{otherwise} \end{cases}$$
$$S_{i,j}(t) = \frac{t - t_i}{t_{i+j} - t_i} S_{i,j-1}(t) + \frac{t_{i+j+1} - t}{t_{i+j+1} - t_{i+1}} S_{i+1,j-1}(t) \tag{35.41}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Depending on the degree of the B-spline, the function is zero on some portion of the unit interval. This is in contrast to the Bernstein polynomials that are strictly non-zero everywhere on the unit interval.

Let x_i^v denote the i^{th} coordinate of the v^{th} mesh node, and let Δx_i^v denote the change in the position of the node due to the morphing process. Let $\Delta \eta_{jk}^i$ denote the displacement of the $(j,k)^{\text{th}}$ control point associated with the Bernstein polynomials in the i^{th} coordinate direction, and let $\Delta \zeta_{jk}^i$ denote the displacement of the $(j,k)^{\text{th}}$ control point associated with the B-splines. If (u^v, v^v) denotes the position of the v^{th} mesh node, then the displacement of the node is defined by the superposition:

$$\Delta x_i^v = \sum_{j=0}^{N_u} \sum_{k=0}^{N_v} \left(\Delta \eta_{jk}^i B_{j,\ell}(u^v) B_{k,m}(v^v) + \Delta \zeta_{jk}^i S_{j,\ell}(u^v) S_{k,m}(v^v) \right) \tag{35.42}$$

The control-point movement for the Bernstein polynomials controls the large-scale smooth deformation, while the control-point movement for the B-splines controls fine-scale motions.

35.2. Using the Adjoint Solver

This section describes the process for loading the adjoint solver module, as well as setting up, running, and postprocessing the adjoint solutions. Also, this section demonstrates the shape modification process that is guided by the adjoint solution.

The typical use of the adjoint solver involves the following steps:

1. Load or compute a conventional flow solution.
2. Specify the observable of interest.
3. Set the adjoint solver controls.
4. Set the adjoint solver monitors and convergence criteria.
5. Initialize the adjoint solution and iterate to convergence.
6. Postprocess the adjoint solution to extract the sensitivity of the observable with respect to boundary condition settings.
7. Postprocess the adjoint solution to extract the sensitivity of the observable with respect to shape of the geometry.
8. Modify boundary shapes based on shape-sensitivity data and recompute the flow solution.

This section provides information about using the ANSYS Fluent adjoint solver in the following sections:

35.2.1. Model Considerations for Using Adjoint Solver
35.2.2. Defining Observables
35.2.3. Solving the Adjoint
35.2.4. Postprocessing of Adjoint Solutions
35.2.5. Modifying the Geometry Using the Design Tool

In addition, see the Fluent Tutorial Guide for more information about using the adjoint solver. (To access tutorials and their input files on the ANSYS Customer Portal, go to http://support.ansys.com/training.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

35.2.1. Model Considerations for Using Adjoint Solver

The current adjoint solver implementation provides basic adjoint solutions that accompany a conventionally-computed flow solution provided certain criteria are met.

35.2.1.1. Basic Assumptions and Consistency Checks
35.2.1.2. User-Defined Sources

35.2.1.1. Basic Assumptions and Consistency Checks

The adjoint solver is implemented on the following basis:

- The flow state is for a steady single-phase flow, or ideal gas, that is either laminar or turbulent.
- For turbulent flows, a *frozen turbulence* assumption is made, in which the effect of changes to the state of the turbulence is not taken into account when computing sensitivities.
- For turbulent flows, standard wall functions are employed on all walls.
- For moving (that is, non-inertial) reference frame problems, the single reference frame (SRF) and multiple reference frame (MRF) approaches are supported (as long as the absolute velocity formulation is used), while the mixing plane model (MPM) is not. Note that for the MRF approach, the adjoint solver does not support having a zone with a frame of motion that is relative to an already moving reference frame.
- Solid zones are supported, as long as they do not use a moving reference frame approach.
- The adjoint solver uses methods that are first order accurate in space by default. If desired, you can select second order accurate methods (see Using the Adjoint Solution Methods Dialog Box (p. 2091)).
- The boundary conditions are only of the following types:
  - Wall (not including thin walls or shells)
  - Velocity inlet
  - Mass-flow inlet
  - Pressure inlet
  - Pressure outlet
  - Symmetry
  - Rotational and translation periodic
- Constant and user-defined sources are supported for the momentum and energy equations; for details on the latter, see User-Defined Sources (p. 2083). Note that temperature dependency is not taken into account with the adjoint solver.

It is important to note that these requirements are not strict conditions for the conventional flow solver, but rather modeling limitations for the adjoint solver.

When the adjoint solver is initialized or an observable is evaluated, and before iterations are performed, a series of checks is performed to determine the suitability of the existing flow solution for analysis with the adjoint solver. Two types of message may appear:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- *Warning message:* There are certain physics models and boundary condition types that are not explicitly modeled in the adjoint solver, but their absence does not disallow you from proceeding with the calculation. In this case, a warning message will be printed that explains the nature of the inconsistency.

  ```
  Checking adjoint setup...
   -- Warning: Model is active but not included in adjoint calculation: P1 radiation model Done
  ```

  The adjoint solver will still run in this case but the quality of the adjoint solution data can be expected to be poorer as a result of the inconsistency. This is because in such cases the unsupported settings will revert to corresponding supported settings for the adjoint solver. Though the calculation will proceed, it is important to note that the results produced should be considered on this basis. When reverting back to the fluid calculation, the original settings will be preserved and the modified settings are not migrated onto the original case. The warning indicates that the setting change will be made automatically and specifically for the adjoint solution.

- *Error message:* There are some model and boundary conditions that are incompatible with the computation of an adjoint solution with the current adjoint solver implementation. In this case, an explanatory error message will be printed in the console window.

  ```
  Checking adjoint setup...
   ** Unable to proceed: Model is active but not compatible with adjoint calculation:
    Transition SST turbulence model
  Done
  ```

  The adjoint solver will not run in this case and changes must be made manually to the settings identified in the console before the solver can be run.

35.2.1.2. User-Defined Sources

User-defined sources for the momentum and/or energy equations that are defined in compiled UDFs can be accounted for in the application of the adjoint solver, provided that the source derivatives with respect to flow variables and cell centroid coordinates are provided. This is achieved by creating the source term UDF definition in the usual fashion, with the exception that a special UDF macro is used, `DEFINE_SOURCE_AE` (The suffix _AE denotes Adjoint Enabled).

`DEFINE_SOURCE_AE` (`name`, `c`, `t`, `dS`, `eqn`)

Argument Type	Description
`symbol name`	UDF name
`cell_t c`	Index that identifies cell on which the source term is to be applied
`Thread *t`	Pointer to cell thread
`real dS[]`	Array that contains the derivative of the source term with respect to the dependent variable of the transport equation, as well as the flow variables and cell centroid position
`int eqn`	Equation number

Function returns

`real`

Consider a source that may depend on velocity, pressure, and cell-centroid coordinates:

$$S\left(u,v,w,p,x_c,y_c,z_c\right)$$

where u, v, and w are the Cartesian velocity components in the cell, p is the pressure in the cell, and $\left(x_c,y_c,z_c\right)$ are the cell centroid coordinates as defined by the `C_CENTROID` macro. If the source strength depends on one or more of these quantities, then the derivatives of the source strength with respect to those variables must be computed and filled in as entries to the `dS[]` array. In particular,

$$\mathrm{dS[D_U]}=\frac{\partial S}{\partial u}$$
$$\mathrm{dS[D_V]}=\frac{\partial S}{\partial v}$$
$$\mathrm{dS[D_W]}=\frac{\partial S}{\partial w}$$
$$\mathrm{dS[D_P]}=\frac{\partial S}{\partial p}$$
$$\mathrm{dS[D_X_CENTROID]}=\frac{\partial S}{\partial x_c}$$
$$\mathrm{dS[D_Y_CENTROID]}=\frac{\partial S}{\partial y_c}$$
$$\mathrm{dS[D_Z_CENTROID]}=\frac{\partial S}{\partial z_c}$$

must be defined in the UDF if there is a dependency of the source upon them. The specification of this derivative information is essential for sensitivities, including shape sensitivity, to be computed correctly by the adjoint solver.

35.2.2. Defining Observables

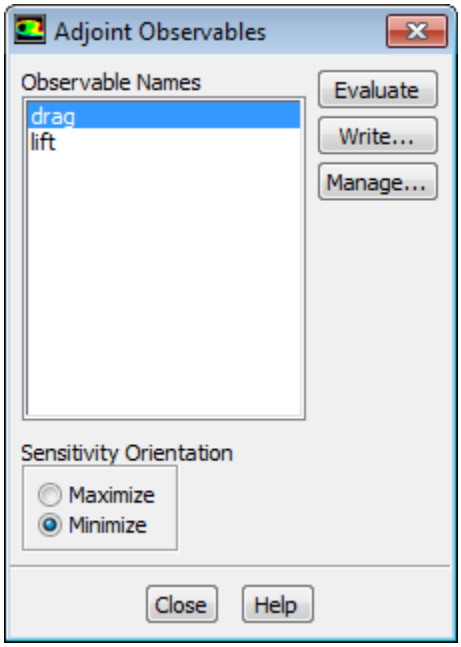
Defining an observable is a key initial step that must be performed for any adjoint calculation. The observable is the quantity for which sensitivities are sought. Observables can be defined based on flow variables, or as operations on other observables. For a list of the types of observables you can define refer to General Observables (p. 2069) and General Operations (p. 2072). You can define multiple observables, but only one observable at a time can be selected for the adjoint sensitivity calculation.

Observables are created and selected in the **Adjoint Observables** dialog box, which is accessed by clicking **Observable...** in the **Design** ribbon tab (**Adjoint-Based** group box). (Figure 35.1: Adjoint Observables Dialog Box (p. 2085)).

Design → **Adjoint-Based** → **Observable...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.1: Adjoint Observables Dialog Box



For more information, see the following sections:

35.2.2.1. Creating New Observables
35.2.2.2. Editing Observable Definitions
35.2.2.3. Selecting an Observable for Sensitivity Calculation

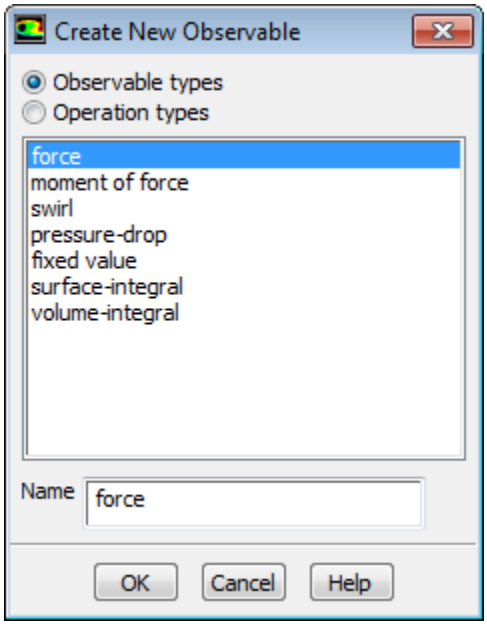
35.2.2.1. Creating New Observables

You can create a new observable by clicking **Manage...** in the **Adjoint Observables** dialog box and then **Create...** in the **Manage Adjoint Observables** dialog box.

In the **Create New Observable** dialog box (Figure 35.2: Create New Observable Dialog Box (Observable Types) (p. 2086)) you can choose from several observable types and operation types. Various types of observable quantities can be defined and each can be given a name. The available types of observables are described in General Observables (p. 2069).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

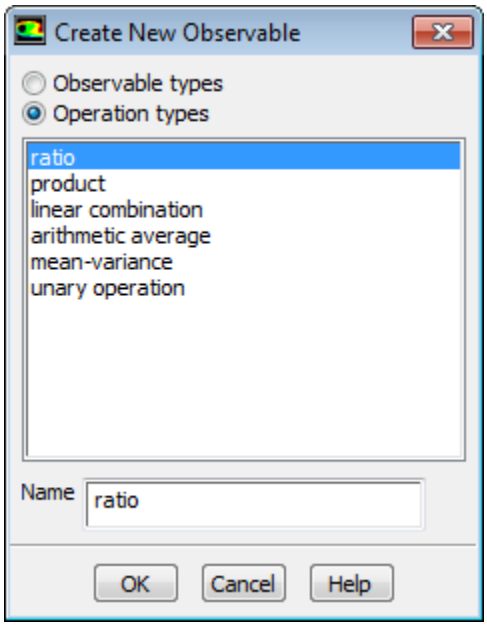
Figure 35.2: Create New Observable Dialog Box (Observable Types)



Select **Observable types** and pick an observable from the list. Keep the default name, or use the **Name** field to designate a different name for the observable of interest. Click **OK** to create the new observable, or click **Cancel** to dismiss the dialog box without creating an observable.

You can also combine existing observables in various ways or apply unary operations to create a wide variety of compound observables. The operations that you can apply to existing observables are described in General Operations (p. 2072).

Figure 35.3: Create New Observable Dialog Box (Operation Types)



Select **Operation types** and choose an operation from the list. Keep the default name, or use the **Name** field to designate a different name for the observable of interest. Click **OK** to create the new observable, or click **Cancel** to dismiss the dialog box without creating an observable.

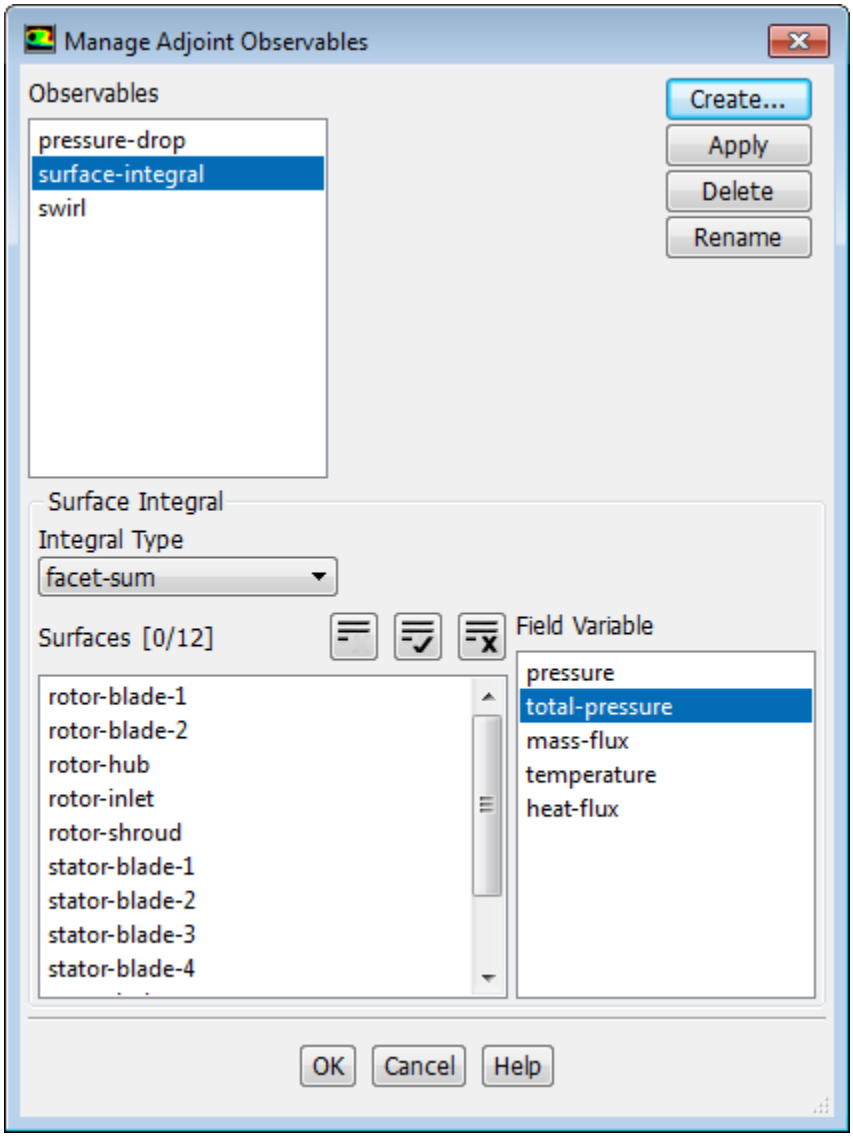
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once created, you must edit the definition of the new observable (Editing Observable Definitions (p. 2087)).

35.2.2.2. Editing Observable Definitions

Once an observable is created, it appears in the **Observables** list. When you select an observable in the **Observables** list, the **Manage Adjoint Observables** dialog box changes to expose various properties that can be assigned for the selected observable.

Figure 35.4: Manage Adjoint Observables Dialog Box



Once the observable properties are defined (Inputs for Observable Types (p. 2088)), click **Apply** to apply the settings and proceed to define other observables, or click **OK** in the **Manage Adjoint Observables** dialog box to apply the settings and close the dialog box. Available observables are described in General Observables (p. 2069).

Note

It is permissible to leave observable definitions incomplete. The **Manage Adjoint Observables** dialog box can be considered as a workspace for the definition and manipu-

lation of observables. Only those operations with complete definitions will appear in the **Adjoint Observables** dialog box. Operations with undefined fields, or operations that depend on themselves, will be excluded from the list of usable observables.

Inputs for Observable Types

The inputs for each type of observable are summarized below:

- For a **force** observable:
  1. Select the walls that are to contribute to the force of interest in the **Wall Zones** list.
  2. Define the direction in which the force is to be computed by entering the components of this direction in the **X Component**, **Y Component**, and **Z Component** (for 3D) fields.
- For a **moment of force** observable:
  1. Select the **X**, **Y**, and **Z** (for 3D) components of the **Moment Center**.
  2. Select the **X**, **Y**, and **Z** (for 3D) components of the **Moment Axis**.
  3. Select a wall in the **Wall Zones** list.
- For a **swirl** observable:
  1. Select the **X**, **Y**, and **Z** (for 3D) components of the **Swirl Center**.
  2. Select the **X**, **Y**, and **Z** (for 3D) components of the **Swirl Axis**.
  3. Select a fluid in the **Fluid Zones** list.
- For a **pressure-drop** observable:
  1. Select the inlets and outlets between which the total pressure drop is to be computed using the **Inlets** and **Outlets** lists.
- For a **fixed value** observable, perform the following:
  1. Select the **Value** of the **Constant**.
- For a **surface-integral** observable:
  1. Select the type of integral from the **Integral Type** drop-down list. Available integral types are described in General Observables (p. 2069).
  2. Select a **Surface** and the corresponding **Field Variable**.
- For a **volume-integral** observable:
  1. Select the type of integral from the **Volume Integral Type** drop-down list. Available integral types are described in General Observables (p. 2069).
  2. Select the **Field Variable** of interest. If the chosen field variable is a vector quantity, you will need to specify a **Direction** along which the field variable will be evaluated.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Under **Zones of Integration**, select whether to integrate over selected **Zones** or **Integrate over a box**.

4. Select the **Zones** for integration under **Zone Settings** or the coordinates of the rectangular (in 2D) or hexahedral (in 3D) integration region under **Box Settings**.

- For a **ratio** observable:

  1. Select an observable from the **Numerator** drop-down list to represent the numerator of the ratio.

  2. Select an observable from the **Denominator** drop-down list to represent the denominator of the ratio.

- For a **product** observable:

  1. Select two observables from the corresponding drop-down list that will be used to compute their product.

- For a **linear combination** observable:

  1. Under **Linear Combination of powers**, select a **Constant** value.

  2. Select the number of **Components**.

  3. For each component, select a corresponding **Coefficient**, an **Observable**, and a **Power**.

- For an **arithmetic average** observable:

  1. Select the number of **Components**.

  2. Select observables from the corresponding **Observable** lists.

- For a **mean variance** observable:

  1. Select the number of **Components**.

  2. Select observables from the corresponding **Observable** lists.

- For a **unary operation** observable:

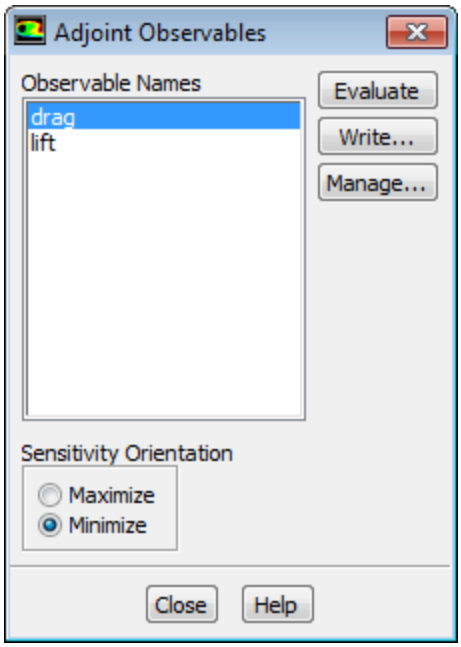
  1. Select an operation from the drop-down list (see General Observables (p. 2069) for a list of available operators).

  2. Select an observable from the corresponding drop-down list upon which the unary operation is to be applied.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

35.2.2.3. Selecting an Observable for Sensitivity Calculation

Figure 35.5: Adjoint Observables Dialog Box



You can select which observable to use for the sensitivity calculation in the list of **Observable Names**.

Note

- Only one observable can be used in any one adjoint calculation. In the **Adjoint Observables** dialog box, the observable that is currently highlighted is the observable that will be used in the sensitivity calculation.
- Any observables that have been created but which are missing required inputs will not appear in the list of **Observable Names**.

Clicking the **Evaluate** button computes the current value of the selected observable quantity and prints the result in the console window. Clicking the **Write...** button provides the option to write the result to a named file.

The **Sensitivity Orientation** determines the sign of the postprocessed sensitivities. For instance, if you select **Maximize** then changes in the direction of positive sensitivities will increase the value of the observable. A standard rule of thumb can be applied: if you want to improve the solution, then follow the direction of the sensitivity vectors. Another standard rule of thumb can also be applied for postprocessed scalars: if you want to improve the solution, then increase values where the sensitivity is positive and/or decrease values where the sensitivity is negative.

35.2.3. Solving the Adjoint

Once an observable is defined as described in Defining Observables (p. 2084), the solution of the adjoint for that observable can be computed based on the current flow solution. The steps for solving the adjoint are similar to those for solving the flow and are detailed in the following sections:

35.2.3.1. Using the Adjoint Solution Methods Dialog Box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

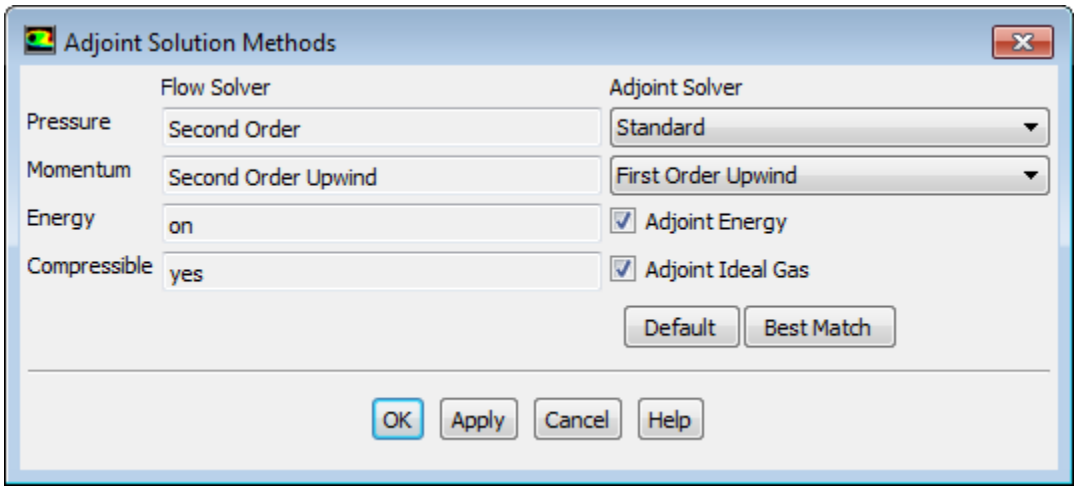
35.2.3.2. Using the Adjoint Solution Controls Dialog Box
35.2.3.3. Working with Adjoint Residual Monitors
35.2.3.4. Running the Adjoint Calculation

35.2.3.1. Using the Adjoint Solution Methods Dialog Box

You can specify the methods used for computing the adjoint solutions in the **Adjoint Solution Methods** dialog box. To open the **Adjoint Solution Methods** dialog box, click **Methods...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → Adjoint-Based → Methods...

Figure 35.6: Adjoint Solution Methods Dialog Box



The **Adjoint Solution Methods** dialog box shows a side-by-side comparison of the schemes used for the flow solver and for the adjoint solver. Using the same scheme for the adjoint solution and the flow solution yields the most accurate discrete derivative calculation when the adjoint solution is converged. However, not all schemes used for the flow solver are supported for the adjoint solver. In these cases an alternate adjoint scheme must be used. This does not typically lead to severe deterioration of the adjoint results quality. Even if the same scheme is available for the adjoint solver this is not always practical because stability may be reduced with some schemes. Therefore, you can use the drop-down lists under **Adjoint Solver** to select alternate schemes as needed.

In some cases it may not be desirable to solve the energy adjoint even if energy is solved in the flow solver. For example, consider an incompressible flow where the specified observable does not involve thermal quantities. In this case the adjoint for the energy equation is identically zero, but its inclusion would add an unnecessary numerical burden. You can disable the **Adjoint Energy** option to avoid solving the energy adjoint.

If the primary flow is a compressible ideal gas, you can specify that the physics of the compressible flow are modeled in the adjoint solver by enabling the **Adjoint Ideal Gas** option. Enabling this option automatically enables the **Adjoint Energy** option as well. If the flow is not a compressible ideal gas, it will be treated as being incompressible for the purposes of the adjoint calculation.

Clicking **Default** will configure the adjoint solver to use the default low-order schemes (**Standard** for pressure and **First Order Upwind** for momentum), which are chosen for their stability. Clicking **Best Match** will attempt to match the adjoint schemes to the flow schemes that should in general provide more accurate calculations at convergence. Where they cannot be matched, the default scheme will be used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

35.2.3.2. Using the Adjoint Solution Controls Dialog Box

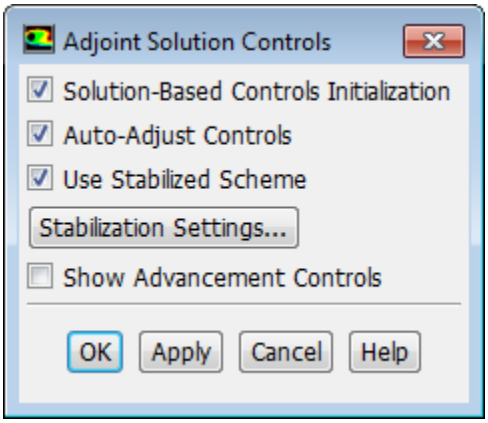
The advancement of the adjoint solution to reach a converged solution is an essential part of the analysis. The solution algorithm for the adjoint solver is similar to the coupled pressure-based solver that is available for conventional flow computations in ANSYS Fluent.

By default, the adjoint solver advancement settings will be automatically adjusted during calculation to encourage convergence, with initial values determined by the state of the flow solution. If needed, you can adjust the advancement controls in the **Adjoint Solution Controls** dialog box.

To open the **Adjoint Solution Controls** dialog box, click **Solver Controls...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → **Adjoint-Based** → **Solver Controls...**

Options



Solution-Based Controls Initialization

When enabled, the advancement controls are selected automatically when the adjoint solution is initialized based on the state of the flow.

Auto-Adjust Controls

When enabled, the convergence of the AMG solver and the adjoint residuals are monitored during solution advancement. Based on the trends observed, the advancement controls are automatically adjusted to encourage reliable solution advancement and convergence. This is especially useful when a new type of problem is being solved for which appropriate settings are not initially clear. The advancement will begin with either user-specified settings or those from **Solution-Based Controls Initialization**. You can enable or disable **Auto-Adjust Controls** at any time during the solution.

If **Auto-Adjust Controls** is enabled, messages will appear as the calculation progresses indicating the adjustments that are being made.

Use Stabilized Scheme

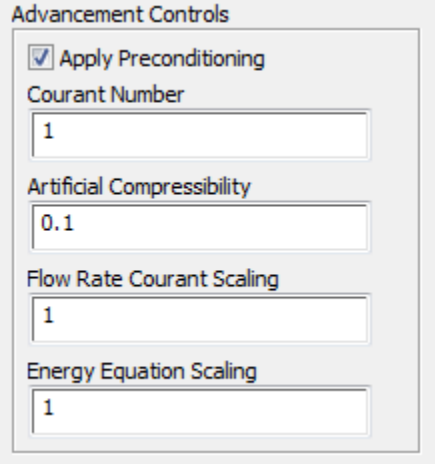
When enabled, stabilization will be applied to the adjoint solution. Click **Settings...** to specify the stabilization type and settings. The details of these settings are described in Stabilized Scheme Settings (p. 2094). A stabilized solution scheme will be required to obtain adjoint solutions for problems at high Reynolds number in which there is strong shear and/or complex geometry.

Show Advancement Controls

Toggles the visibility of the various advancement controls for direct user-specification.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Advancement Controls



Apply Preconditioning

Enables solution preconditioning. This is needed for most cases involving turbulent flow. If preconditioning is enabled, the following controls are available:

Courant Number

A higher number corresponds to a more aggressive advancement of the computation at the risk of instability. Disabling preconditioning corresponds to an infinite Courant number.

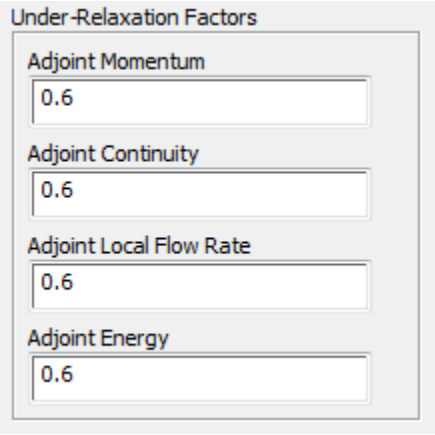
Artificial Compressibiilty

A nonzero value introduces artificial compressibility into the computation of the adjoint continuity equation. A value of `1.0` or less is reasonable.

Flow Rate Courant Scaling , Energy Equation Scaling

These values should be larger than zero (default values are `1`). A smaller value implies a less aggressive algorithm that encourages stability of the AMG linear solver.

Under-Relaxation Factors

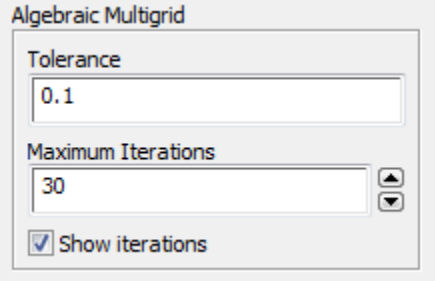


Adjoint Momentum , Adjoint Continuity , Adjoint Local Flow Rate , Adjoint Energy

Each of these can be set to a value between `0.0` to `1.0`. A higher value leads to a more aggressive algorithm that is less likely to be stable. A value of `1.0` for each can be used for some simple cases without difficulty.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Algebraic Multigrid



Tolerance
The tolerance used for judging convergence.

Maximum Iterations
The maximum number of inner iterations of the AMG solver.

Show Iterations
If enabled, a more verbose iteration history is printed in the text console during iterations. The details of the inner iteration can be useful when deciding on appropriate **Courant Number**, **Artificial Compressibility**, and **Flow Rate Courant Scaling**. If many inner iterations are needed, or if the inner iterations diverge, this signals that a reduction in **Courant Number** may be needed. Alternatively, an increase in **Artificial Compressibility** or a reduction in the **Flow Rate Courant Scaling** may be sufficient for the AMG iterations to converge.

35.2.3.2.1. Stabilized Scheme Settings

If you choose to use one of the stabilization schemes (Adjoint Solver Stabilization (p. 2077)) you will need to specify the scheme and settings in the **Stabilized Scheme Settings** dialog box (accessed by enabling **Use Stabilized Scheme** and clicking **Settings...** in the **Adjoint Solution Controls** dialog box).

The stabilization scheme settings are described in the following sections:
35.2.3.2.1.1. Modal Stabilization Scheme
35.2.3.2.1.2. Spatial Stabilization Scheme
35.2.3.2.1.3. Dissipation Scheme

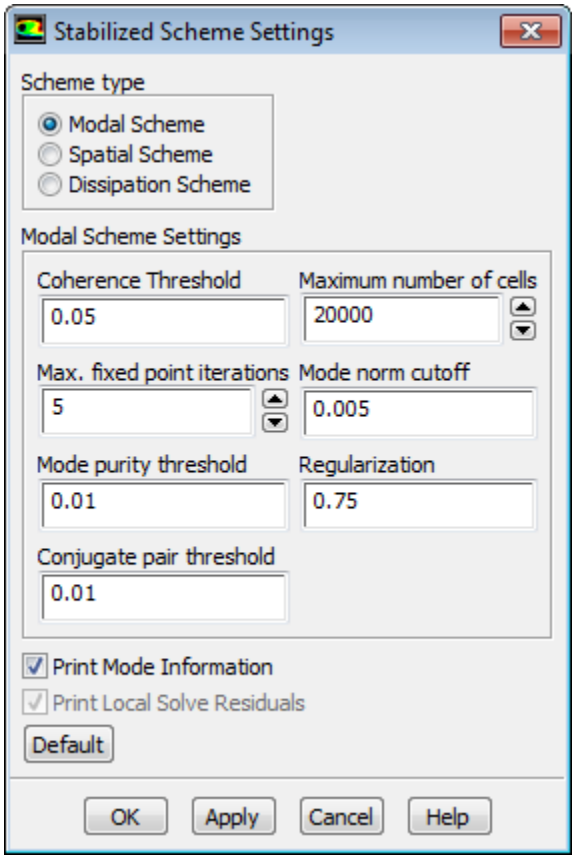
35.2.3.2.1.1. Modal Stabilization Scheme

The behavior of the modal scheme is as follows. As the calculation progresses the solution is monitored for unstable growing patterns or modes as the adjoint solution is corrected by the primary advancement algorithm. The first stage of the stabilization scheme involves a lightweight monitoring process to screen for any unstable patterns. If the calculation is progressing in a stable manner there is no indication even that the stabilization scheme is operating. If a candidate instability appears then it is monitored. In the event that unstable behavior that cannot be handled by the primary advancement scheme becomes evident a more intensive process is activated. Unstable patterns are refined using a fixed point iteration scheme so that they can be handled cleanly and advanced in a stable manner using an alternative to the primary advancement scheme.

The settings for the modal scheme are described below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.7: Stabilized Scheme Settings for Modal Scheme



Coherence Threshold

controls the preliminary screening for growth. It defines the threshold for relative variance of growth between iterations at which a more detailed search is activated. A smaller value will tend to delay the activation of the more detailed search for unstable growth at the risk of allowing unstable growth to continue for more iterations.

Max. Fixed Point Iterations

is the maximum number of iterations taken to refine the unstable pattern during the more detailed search.

Mode Purity Threshold

is the tolerance for an acceptable unstable pattern. A smaller value will lead to a more pure unstable mode being identified. This may occur at the expense of a larger number of fixed point iterations. If the purity threshold is not met after the maximum specified number of iterations then the unstable pattern is rejected.

Conjugate Pair Threshold

is the threshold for inclusion of a second unstable mode alongside a candidate mode, forming a conjugate pair. This corresponds to a pseudo-time-periodic instability, versus purely exponential growth. Such instabilities can occur in some cases. Increasing this value will increase the occurrence of a second mode being included.

Maximum Number of Cells

is the largest number of cells allowed for an unstable pattern that will be handled by the stabilization scheme. The problematic instabilities for an adjoint solver are often localized in space to a small number of cells out of the entire flow domain. However, there can be transiently growing corrections to the adjoint solution that masquerade as unstable patterns. This cell limit suppresses such false patterns from consideration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mode Norm Cutoff
serves to identify the main body of an unstable pattern and exclude the peripheral spatial parts of the mode that are of small amplitude. If the norm cutoff were set to zero, all unstable modes would involve all cells in the domain. Therefore, reducing this value increases the number of cells that are included in an unstable mode.

Regularization
acts to regularize the advancement of the unstable mode components. The stiffness of the adjoint governing equations can give rise to difficulty in discerning the unstable pattern from nearby stable patterns. Increasing the regularization tends to overcome this difficulty and adds stability to the calculation at the expense of potentially slower convergence. Valid values are between `0` and `1`.

Print Mode Information
enables printing of stabilization information to the console.

When using the modal stabilization scheme, the following behavior can be observed:

- When the primary advancement scheme is proceeding in a stable manner, the stabilization scheme will remain idle and no output will be generated.

- When a candidate unstable pattern appears it will be tracked and a message will appear with information about the detected mode:

```
Mode growth:    1.34390e+00  Coherence:    8.28546e-02
```

  In the above example, the message indicates that an unstable pattern that grows by more than 34% in one iteration is present. The value of the Coherence corresponds to the variance in growth between iterations.

- When a candidate unstable pattern is identified that meets the coherence threshold, the secondary refinement stage is activated:

```
Mode growth:    1.35752e+00  Coherence:    3.95870e-02
Growing pattern cell count: 929
Isolating new mode
Iteration: 0  Growth rate:    1.42665e+00   Residual:    5.88196e-02
Iteration: 1  Growth rate:    1.41329e+00   Residual:    1.34600e-02
Iteration: 2  Growth rate:    1.41227e+00   Residual:    2.25348e-02
New growing mode with 597 cells
```

  If the growing pattern cell count exceeds **Maximum Number of Cells** the refinement procedure is postponed. Likewise, if after refinement the number of cells involved exceeds the specified limit the mode is rejected. Each iteration corresponds to a refinement of the unstable pattern. The adjoint solution itself is not advanced during this process. The residual corresponds to the purity of the mode and must eventually fall below the **Mode Purity Threshold** for the mode to be accepted. A minimum of 3 iterations is taken so that the occurrence or absence of a conjugate pair can be verified.

- The presence of the sometimes violent unstable growth that can occur gives a jagged appearance to the adjoint residual plots. However, the underlying trend of the residual plots should correspond to a converging adjoint solution process.

The unstable patterns of solution advancement are specific to the flow solution, choice of discretization schemes, and solution advancement controls for the adjoint solver. If any of these values changes, then the unstable modal patterns must be recomputed so that the stabilization scheme will function to full effect. In the event that any of these parameters is changed and the adjoint solution is restarted a mode recalibration process will be initiated. It should be noted that if there are many unstable modes that have been identified then this recalibration may take some time.

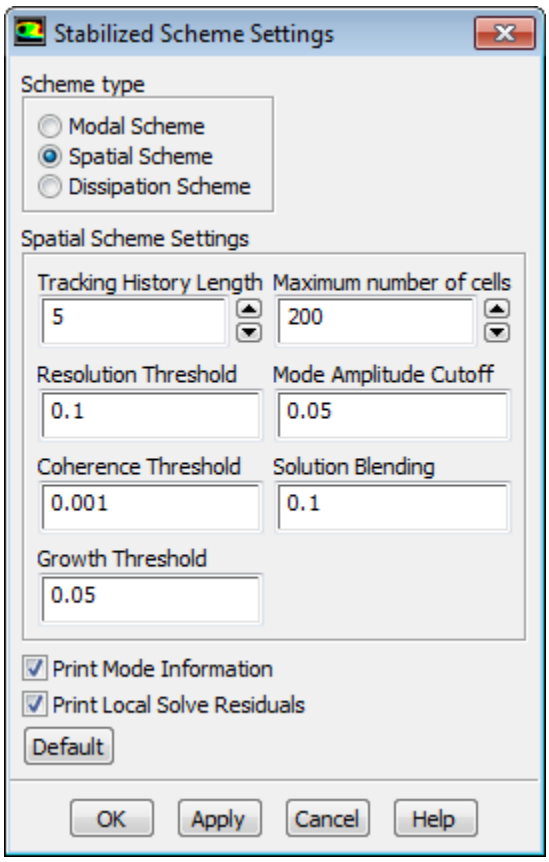
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In contrast, the patterns of unstable growth are not specific to the observable that has been selected. Given that there is computational effort needed to identify the instabilities, a separate initialization process is available just for the unstable modal patterns. This allows the adjoint solution itself to be initialized for a new observable while retaining the knowledge of how to stabilize the solution advancement. A much smoother path to solution for the second and subsequent observables is then achieved.

35.2.3.2.1.2. Spatial Stabilization Scheme

The spatial scheme operates by identifying parts of the domain where unstable growth is occurring and applying a more stable scheme. The unstable mode tracking and handling is done in an automated manner. Several settings are exposed, but are recommended for expert users only. When the stabilized scheme is used and the **Settings...** button is selected, the following dialog box will appear (Figure 35.8: Stabilized Scheme Settings for Spatial Scheme (p. 2097)):

Figure 35.8: Stabilized Scheme Settings for Spatial Scheme



The four items on the left side of the dialog box relate to unstable mode tracking and selection, while the items on the right provide options for the response once a mode is identified. The values have the following meaning:

Tracking History Length
: defines the number of iterations that are employed in the unstable mode identification process. A range between 2 and 5 may be chosen. The longer the tracking history, the better the quality of the identification process.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Resolution Threshold

defines a threshold for the separation between modes based on their amplitudes. A value of 0.1 implies that the second most-dominant mode must be 0.1 of the amplitude of the primary mode before an unstable mode can be considered as being adequately resolved.

Coherence Threshold

defines a threshold that must be met for the closeness of the mode to pure exponential growth as the iterations progress. A smaller number means that a tighter tolerance must be met before an unstable mode is considered as having been identified.

Growth Threshold

defines the growth rate threshold for unstable modes that must be met before the algorithm responds to the presence of the mode. The growth threshold defines the number of iterations that would have to take place for the mode to grow by one order of magnitude. That is, a value of 0.01 signifies that a mode that would grow one order of magnitude or more in 100 iterations will be handled. A negative value for this threshold is not recommended as multiple stable modes may be tracked.

Maximum Number of Cells

defines a limit on the number of cells for which stabilization will be applied when an unstable mode is located.

Mode Amplitude Cutoff

defines the fraction of the peak mode amplitude beyond which cells will be included for stabilization.

Solution Blending

defines an under-relaxation factor for blending the stabilized part of the scheme with the standard advancement scheme. A default of 0.1 is chosen. The value should lie between 0 and 1.

Print Mode Information

(when enabled) leads to details of the unstable mode tracking process being printed in the console window. The following is an example of what is printed when a mode is resolved partially:

```
Mode present> Growth :    2.38166e-01  Coherence  :    1.27858e+00
Resolution Threshold :    1.00000e-01  Resolution :    1.32611e-01
```

The following is an example of what is printed when a mode becomes more fully resolved:

```
 Mode present> Growth :    1.35318e-01  Coherence  :    2.84133e-04
 Resolution Threshold :    1.00000e-01  Resolution :    2.75312e-04
 Growth Threshold     :    5.60193e-02  Growth     :    1.35318e-01
 Coherence Threshold  :    1.00000e-02  Coherence  :    2.84133e-04
 Local stabilization required: Instability detected in 5 cells
```

The final line only appears when a coherent and resolved instability has been identified successfully. Subsequently, the solution advancement algorithm automatically adjusts to eliminate this unstable behavior.

Print Local Solve Residuals

(when enabled) leads to details of the residuals for the local solution process being printed in the console window. An example of what is printed is given below:

```
Iter   Adjoint-continuity  Adjoint-xMom     Adjoint-yMom      Adjoint-Flowrate
 ....
  27       1.76334e-03      1.57503e-01      1.26984e-01        2.92618e-01
Local (%)     61.02095         57.41937         62.09185           99.99136
```

The percentage residual indicates the fraction of the total residual that is associated with the local solution process.

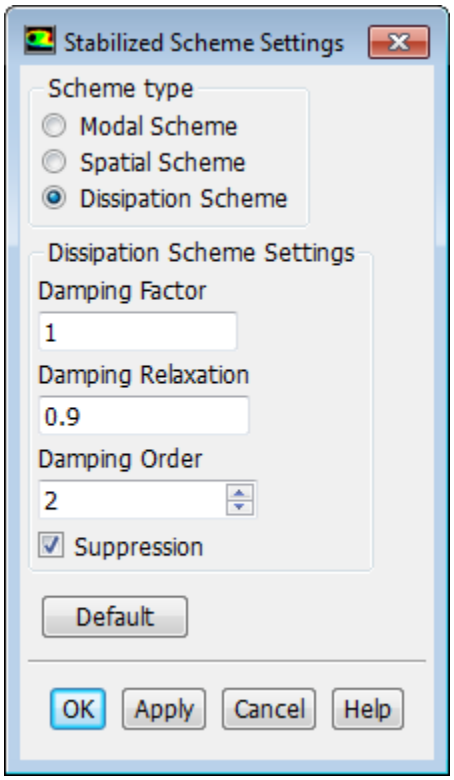
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default
provides a set of default values for the various fields in the dialog box.

35.2.3.2.1.3. Dissipation Scheme

The dissipation scheme operates by introducing nonlinear damping strategically into the calculation domain. The strategy is intended to provide minimal intervention in order to damp the growth of instabilities that lead to adjoint solution divergence. A marker is tracked, based on the state of the adjoint solution, and the damping is applied directly to the adjoint solution in regions where the marker becomes large.

Figure 35.9: Stabilized Scheme Settings for Dissipation Scheme



The following parameters can be set:

Damping Factor
The overall level of dissipation is proportional to this value although the damping level is determined ultimately through a nonlinear process.

Damping Relaxation

The damping relaxation can be used to control the rate at which the dissipation is updated as the adjoint solution progresses. As you decrease the value from 1, the rate at which the dissipation is updated is decreased.

Damping Order
The spatial order of the dissipation. A higher order leads to more intense and localized damping. This can typically be set to be one order larger than the adjoint calculation spatial order.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Suppression

As part of the dissipation scheme, the growth of instabilities is stopped by the effect of the dissipation; enabling the **Suppression** option ensures that these undesirable patterns will then also decay as the calculation progresses.

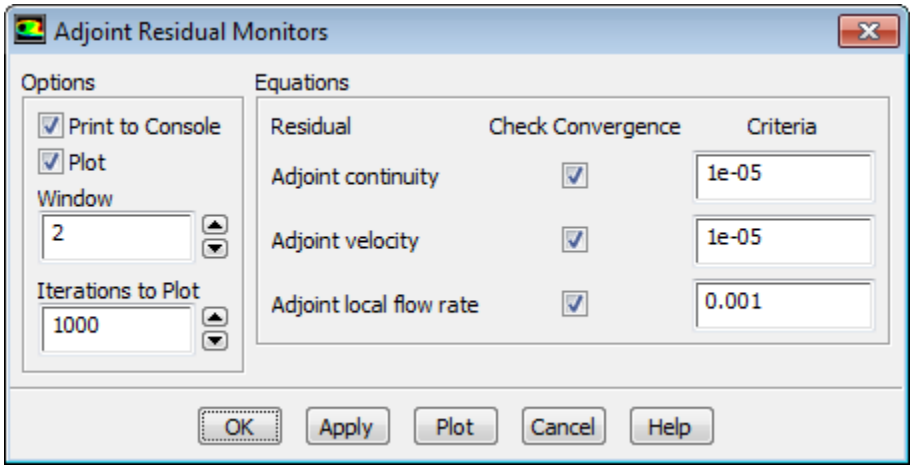
Since the order of discretization of the dissipation scheme is usually set higher than the adjoint, the formal order of accuracy of the adjoint solution is unaffected by the addition of dissipation. However, regions of intense dissipation can appear for some cases when using this scheme. This can sometimes appear as isolated spots and streaks in the adjoint solution on surfaces. The scale of these features is such that they are often easily smoothed during postprocessing to generated design changes.

35.2.3.3. Working with Adjoint Residual Monitors

The progress of the iterations of the adjoint solver and the monitoring of the convergence is controlled in the **Adjoint Residual Monitors** dialog box. This dialog box is accessed by clicking **Monitors...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → Adjoint-Based → Monitors...

Figure 35.10: Adjoint Residual Monitors Dialog Box



The steps to define the monitor behavior are as follows:

1. Decide whether or not the residuals are to be printed in the console by setting the **Print to Console** check box as desired.

2. Decide whether or not the residuals are to be plotted in the main window by setting the **Plot** check box as desired.

3. Set the id of the window in which the adjoint residuals are to appear in the **Window** field.

4. Set how many iterations are to be shown in the residual curves that are plotted in the **Iterations to Plot** field.

5. Enable and/or disable those values that are to be used as criteria for convergence, and set the **Criteria** in each case. The options are to test the residuals for the **Adjoint continuity** and/or **Adjoint velocity** and/or **Adjoint local flow rate** equations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

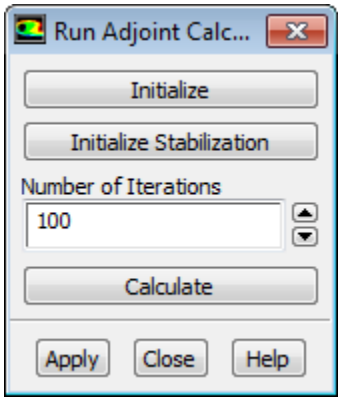
Click the **OK** or **Apply** buttons to confirm that the settings are acceptable. Clicking **Plot** will cause existing adjoint residuals to be plotted in the main graphics window.

35.2.3.4. Running the Adjoint Calculation

Initialization and execution of the adjoint solver is accomplished in the **Run Adjoint Calculation** dialog box. This dialog box is accessed by clicking **Calculate...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → **Adjoint-Based** → **Calculate...**

Figure 35.11: Run Adjoint Calculation Dialog Box



The function of this dialog box is as follows:

Initialize
sets the value of the adjoint velocity and pressure to zero everywhere in the problem domain.

Initialize Stabilization
clears all of the unstable modes that have been identified in calculations using the modal stabilization scheme, but leaves the adjoint solution unchanged. Only available when **Modal** is selected in the **Stabilized Scheme Settings** dialog box.

Calculate
advances the adjoint solver by the **Number of Iterations** specified in the adjacent field.

Depending on the monitor settings, the residuals may be printed in the console and/or plotted in the main graphics window.

35.2.4. Postprocessing of Adjoint Solutions

Adjoint solution data can be postprocessed so that it provides both qualitative and quantitative views of the effect of many types of change that may be imposed on a system. While shape changes are often of particular interest there is a very rich data set, one as large as the original flow field, available for exploration. Postprocessing tools are provided with the intention of permitting the adjoint data to be mined in such a way that it provides useful supporting information for an engineer who is making design decisions for a system, or has questions about the reliability of the original flow calculation.

Since the ANSYS Fluent adjoint solver is a discrete adjoint solver, the primitive adjoint solution data provides sensitivity to changes cell-wise for the computational mesh. Normalization of these results by the cell volume provides a *mesh-independent* view into the data set.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Information regarding postprocessing the adjoint solutions can be found in the following sections:
35.2.4.1. Field Data
35.2.4.2. Scalar Data

35.2.4.1. Field Data

Adjoint solution data can be postprocessed using standard ANSYS Fluent postprocessing tools including contours, vectors, xy-plots, histograms, and surface and volume integrals.

In the **Contours** dialog box, under **Sensitivities...**, you can find the following fields:

Magnitude of Sensitivity to Body Forces (Cell Values)
This field is the magnitude of the adjoint velocity primitive field. This field can be interpreted at the cell level as the sensitivity of the observable to a body force on the cell, or any factors that may change the momentum balance on the cell. As such it is a mesh-dependent quantity. This field is often observed to be large, for example, upstream of a body for which drag sensitivity is of interest, with the field diminishing in the upstream direction. This indicates the interference effect for an object positioned at various locations upstream of the object of interest.

Sensitivity to Body Force X-Component (Cell Values), Sensitivity to Body Force Y-Component (Cell Values), and Sensitivity to Body Force Z-Component (Cell Values)
These are the components of the adjoint velocity primitive field. These fields show the sensitivity of the observable to the various components of a body force that may be applied to a cell, or other factors that may change the momentum balance on the cell. As such, it is a mesh-dependent quantity.

Sensitivity to Mass Sources (Cell Values)
This field provides a plot of the primitive adjoint pressure field. This field can be interpreted at the cell level as the sensitivity of the observable with respect to any changes to the mass balance on the cell. As such, it is a mesh-dependent quantity.

Sensitivity to Energy Sources (Cell Values)
This field is available when the energy adjoint is solved and is the primitive adjoint temperature field. It can be interpreted at the cell level as the sensitivity of the observable with respect to changes in the thermal energy balance of the cell. As such, it is a mesh-dependent quantity.

Magnitude of Sensitivity to Body Forces
This field is the magnitude of the adjoint velocity primitive field normalized by cell volume. This field can be interpreted as the magnitude of the sensitivity of the observable to body force per unit volume. It can be used to identify regions in the domain where small changes to the momentum balance in the flow can have a large or small effect on the observable. This field is often observed to be large, for example, upstream of a body for which drag sensitivity is of interest, with the field diminishing in the upstream direction. This indicates the interference effect for an object positioned at various locations upstream of the object of interest. This field is normalized so that, in principle, it shows a mesh-independent quantity. In practice, this field has features that are often correlated with mesh structure. This is not unexpected. In fact, the adjoint solution field is providing very useful insight into regions of the flow domain where the observation of interest is potentially sensitive to particular features of the mesh and discretization process that affect the local momentum balance.

Sensitivity to Body Force X-Component, Sensitivity to Body Force Y-Component, and Sensitivity to Body Force Z-Component (in 3D) fields
These are the components of the adjoint velocity primitive field normalized by cell volume. This field can be interpreted as the magnitude of the sensitivity of the observable to components of a body force per unit volume. Consider a body force distribution, expressed as a force per unit volume. The

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

integral of the vector product of that distribution with the components of this field gives a first-order estimate of the net effect of the body force on the observation.

Sensitivity to Mass Sources

This field is the primitive adjoint pressure field normalized by cell volume. This field can be interpreted as the sensitivity of the observable with respect to mass sources or sinks in the domain. Consider a mass source/sink distribution, expressed as mass flow rate per unit volume. The integral of that distribution, weighted by the local value of this field, gives the effect of the sources/sinks on the observation. This field is normalized so that, in principle, it shows a mesh-independent quantity. In practice, this field has features that are often correlated with mesh structure. This is not unexpected. In fact the adjoint solution field is providing very useful insight into regions of the flow domain where the observation of interest is potentially sensitive to particular features of the mesh and discretization process that affect local mass balance. When plotted on a boundary, this field indicates the effect of the addition or removal of fluid from the domain upon the quantity of interest. It is important to note that in this scenario the effect of the momentum of the fluid that is added or removed is not taken into account. The boundary velocity sensitivity should be plotted if that effect is also of interest.

Sensitivity to Energy Sources

This field is available when the energy adjoint is solved and is the primitive adjoint temperature field normalized by cell volume. It can be interpreted at the cell level as the sensitivity of the observable with respect to thermal energy sources or sinks in the domain. This field is normalized so that, in principle, it is a mesh-independent quantity.

Sensitivity to Viscosity

This field shows the sensitivity of the quantity of interest to variations in the turbulent effective viscosity for a turbulent problem, or the laminar viscosity in a laminar case. The sensitivity is normalized by the cell volume to account for cell size variations in the mesh.

Shape Sensitivity Magnitude

This field is the magnitude of the sensitivity of the observable with respect to a deformation applied to the mesh (both boundary and interior mesh). When plotted on the surface of a body the locations where this quantity is large indicates where small changes to the surface shape can have a large effect on the observable of interest. If the shape sensitivity magnitude is small then the effect of shape changes in this region can be expected to have a small effect on the observable of interest. When viewing this field, it is often observed that the magnitude varies by many orders of magnitude. Contour plots will clearly draw attention to regions with the highest sensitivity (often sharp edges and corners). However, it should be remembered that a relatively small surface movement that is distributed over a large area can have a cumulative effect that is large.

Normal Shape Sensitivity

This field shows the normal component of the shape sensitivity. A positive value indicates an orientation directed into the domain, while a negative value indicates that the shape sensitivity is oriented outwards from the domain. This field eliminates the component of the vector shape sensitivity field that lies in the plane of the wall.

Normal Optimal Displacement

This field shows the normal component of the optimal displacement computed from the adjoint solution. This field is defined only for portions of walls lying within the control-volume specified for morphing. The size of the optimal displacement is determined by the scale factor that is chosen for the morphing. A positive value of displacement indicates that the surface will be displaced into the flow domain, whereas a negative value of displacement corresponds to wall movement outwards from the flow domain. This field eliminates the component of the optimal displacement vector that lies in the plane of the wall.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

log10(Shape Sensitivity Magnitude)

In view of the large range of values possible for the shape sensitivity magnitude, a convenience function that plots $\log_{10}$ of the magnitude is provided. This allows the importance of the surfaces in a domain to be ranked more easily based on how they affect the observation of interest when they are reshaped.

Shape Sensitivity X-Component, Shape Sensitivity Y-Component, and Shape Sensitivity Z-Component (in 3D) fields

These fields are the individual components of the sensitivity of the observable of interest with respect to the mesh node locations. It is plotted as cell data and is computed as the average of the nodal sensitivities for a given cell, divided by the cell volume. Note that for this discrete adjoint solver the sensitivity of the result with respect to node locations both on and off boundaries is computed. The normalization by cell volume indicates that the fields that are plotted are the weighting factors for a continuous spatial deformation field. (Note that the nodal sensitivity data itself is used when mesh morphing is performed, and predictions about the effect of shape changes are made.)

Sensitivity to Boundary X-Velocity, Sensitivity to Boundary Y-Velocity, and Sensitivity to Boundary Z-Velocity (in 3D) fields

These fields are defined on those boundaries where a user-specification of a boundary velocity is made for the original flow calculation. This includes no-slip walls. The field shows how sensitive the observable of interest is to changes in the boundary velocity at any point. It is interesting to note that even though the original boundary condition specification may be for a uniform velocity on the domain boundary, the effect of a non-uniform velocity perturbation is available, The effect of any specific boundary velocity change can be estimated as an integral of the vector product of the change to the velocity with the plotted sensitivity field. A plot of this quantity on a velocity inlet, for example, can be very useful for assessing whether or not the inlet is positioned too close to key parts of the system. That is, it addresses the question of whether or not the flow domain is too small to achieve a successful computation of the performance measure of interest. Viewing this field will also indicate whether or not the assumption of a uniform inflow is adequate.

Sensitivity to Boundary Pressure

This field is defined on boundaries where there is a user-specified pressure as part of a boundary condition, such as on a pressure outlet. The field shows the sensitivity of the observation of interest to variations in the boundary pressure across the flow boundary. It is interesting to note that even though the original boundary condition specification may be for a uniform pressure on the domain boundary, the effect of a non-uniform pressure perturbation is available, The effect of any specific boundary pressure change can be estimated as an integral of the product of the change to the pressure with the plotted sensitivity field. Viewing this field will also indicate whether or not the assumption of a uniform pressure is adequate for the simulation.

Sensitivity to Boundary Temperature

This field is available when the energy adjoint equation is solved and is defined on boundaries where a temperature boundary condition is applied. This includes walls, velocity inlets, mass-flow inlets, pressure inlets, and pressure outlets where a backflow temperature may be specified. The field shows the sensitivity of the observation of interest to variations in the boundary temperature across the boundaries. Note that even if the original boundary condition specification is for a uniform temperature on the boundary, the effect of a non-uniform temperature perturbation is available. The effect of any specific boundary temperature change can be estimated as an integral of the product of the change to the temperature with the plotted sensitivity field. This field can be used to indicate whether or not the assumption of a uniform temperature is adequate for the simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sensitivity to Boundary Heat Flux

This field is available when the adjoint energy equation is solved and is defined on walls where a heat flux boundary condition is imposed. The field shows the sensitivity of the observation of interest to variations in the boundary heat flux through the wall. Its properties are analogous to those of Sensitivity to Boundary Temperature.

Sensitivity to Flow Blockage

This field is provided as a convenient tool for identifying portions of the flow domain where the introduction of blockages or obstructions in the flow can affect the observation of interest. Consider a blockage in the flow that generates a reaction force on the flow that is proportional to the local flow speed, and acting in the opposite direction to the local flow: $F=-\alpha(r)v$ where α is a local coefficient for the reaction force. The local contribution of this force on the observation of interest is determined by the vector product of this force with the adjoint velocity field. The flow blockage field that is plotted is $-v\cdot\tilde{v}$, namely the negative of the vector product of the flow velocity and the adjoint velocity (Cell Value).

Adjoint Local Solution Marker

This field, intended for expert users, can be plotted to identify those portions of the flow domain where the stabilized adjoint solution advancement scheme is applied. It is preferable to plot this with the **Node Values** de-selected in the **Contours** dialog box. In this case, the **Adjoint Local Solution Marker** will take a value between 0 and 1. The **Mode Amplitude Cutoff** defined in the **Stabilized Scheme Settings** dialog box defines the lower bound for cells where the stabilized scheme is applied.

The surface shape-sensitivity fields contain the derivatives of the chosen observable with respect to the position of the bounding walls of the problem.

In the **Vectors** dialog box, under **Vectors of...**, you can find the following custom vector fields:

Sensitivity to Body Forces (Cell Values)

This vector field shows how sensitive the observable of interest is to the presence of body forces within the flow. A body force that locally has a component in the direction of the body-force sensitivity vector will lead to an increase in the observation of interest. The larger the sensitivity vector, the larger the effect that a body force can have on the observation of interest.

Sensitivity to Body Forces

This vector field shows how sensitive the observable of interest is to the presence of body forces within the flow. It is normalized by the local cell volume so that it is *mesh-independent* data. A body force that locally has a component in the direction of the body-force sensitivity vector will lead to an increase in the observation of interest. The larger the sensitivity vector the larger the effect that a body force can have on the observation of interest. The first-order effect of a body force distribution per unit volume can be computed as a volume integral of the vector product of the body force distribution with this field.

Sensitivity to Shape field defined on walls

This vector field shows the postprocessed adjoint solution, independent of any morphing settings, that defines the sensitivity of the observable of interest to movement of the walls. Deformation of a wall where this vector is large can be expected to have a significant effect on the observable. In contrast, deformations of the wall in locations where this vector is small in magnitude, to first order, will have no effect on the observable.

Optimal Displacement

The optimal displacement field is defined once a design change has been computed using the design tool. This vector field shows the optimal displacement based on the design goals that have been specified and any prescribed boundary motions. Note that when plotting this vector field, if the **Auto Scale** option is

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

deselected, and the vector **Scale** option is set to 1, then the vectors as shown display the absolute displacement that will occur.

Sensitivity to Boundary Velocity

This sensitivity field is defined on boundaries where velocities are specified as an input for the boundary condition. This includes no-slip, and slip walls. When plotted, this field illustrates where a change to the boundary velocity can affect the observation of interest. When plotted on a wall, it shows how the imposition of a nonzero velocity condition on the wall will affect the observation. This can include movement in the plane of the wall itself. When plotted, for example on a velocity inlet, this field illustrates how local adjustments to the velocity of the incoming flow affect the observation of interest. Integrating a potential change to the velocity field, weighted by this sensitivity field over the boundary provides a first order estimate of the effect of the change on the observation of interest.

Sensitivity to Boundary Mass Flux

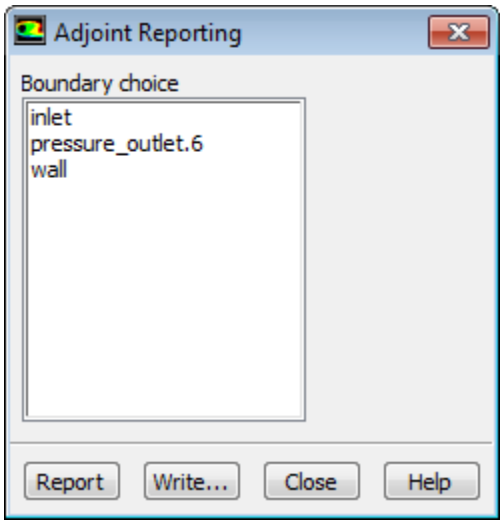
This sensitivity field that can be used to visualize the effect of adding or removing fluid via a wall-normal jet. This can be used, for example, to identify regions on walls where the introduction of suction could have a significant effect on the observable that has been specified. A plot of the **Sensitivity to Boundary Velocity** in general provides a richer view, but sometimes at the expense of the clarity of the visualization.

35.2.4.2. Scalar Data

The computed adjoint solution can provide sensitivity information for individual boundary condition settings through the **Adjoint Reporting** dialog box. This dialog box is accessed by clicking **Reporting...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → Adjoint-Based → Reporting...

Figure 35.12: Adjoint Reporting Dialog Box



Boundary condition sensitivity data is retrieved as follows:

- Select a single boundary of the problem in the **Boundary choice** selection box.
- Click **Report** to see the boundary condition settings and the sensitivity of the observable with respect to those settings. An example of a report is shown below:

```
Velocity inlet id 5
Velocity magnitude = 4.000000000e+01 (m/s),
Sensitivity = 5.429127866e+01 ((n)/(m/s))
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In this case, the report shows that for every change of the boundary velocity by 1 m/s, a change in the predicted observable (in this case a force) of 54.2 N is expected. This prediction is based on a linear extrapolation.

- Click **Write...** to write the report for the selected boundary to a file.

35.2.5. Modifying the Geometry Using the Design Tool

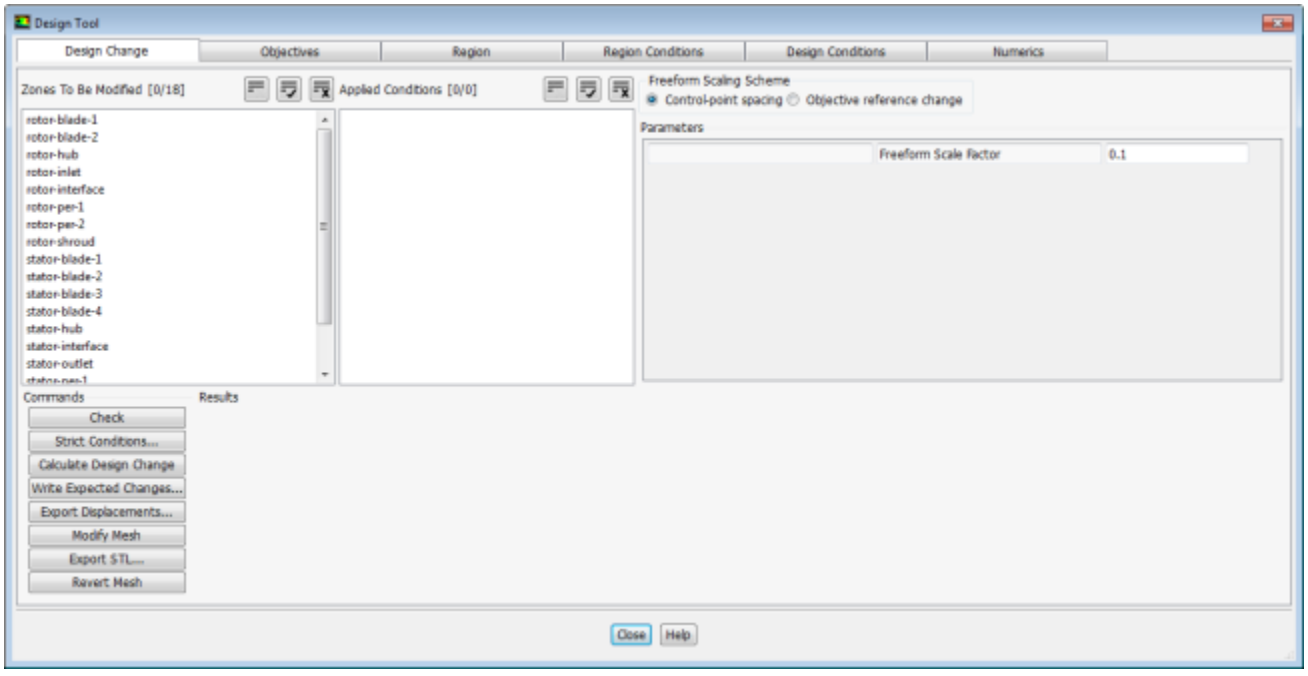
Tools to modify the boundary and interior mesh of the problem based on the adjoint solution are provided in the **Design Tool** dialog box. The **Design Tool** uses computed adjoint sensitivity data to find an optimal design change satisfying one or more goals or constraints, and to predict the resulting changes in observable values. Among the goals that can be specified in the **Design Tool** are:

- minimization, maximization, or targeted changes of single or multiple observable values
- prescribed deformations of selected geometry
- general constraints on deformations including restrictions on direction of motion, symmetry, and boundary conditions.
- equality and/or inequality constraints on geometry (fixed walls, bounding boxes, and so on).

The **Design Tool** is accessed by clicking **Design Tool...** in the **Design** ribbon tab (**Adjoint-Based** group box).

Design → Adjoint-Based → Design Tool...

Figure 35.13: Design Tool Dialog Box



The general procedure to use the Design Tool is as follows.

1. Select those boundaries that are free to be deformed in the **Zones To Be Modified** field on the **Design Change** tab. Boundaries that are not selected in this box that intersect the control volume will be constrained not to move. This is useful if there are walls which, for design reasons, must

not move. Note that if you have a two-sided wall that you want to deform, it is recommended that you select both the wall and the corresponding wall-shadow.

2. Define the region that will be modified in the **Region** tab. (Defining the Region for the Design Change (p. 2108))

3. Define conditions on the deformation region such as number of control points, symmetry, directional invariance, and boundary continuity. (Defining Region Conditions (p. 2110))

4. Compute and export the sensitivities from the adjoint solution for each observable of interest. (Exporting Sensitivity Data (p. 2111))

5. Import the sensitivity data for each observable that will participate in the design change and specify the optimization goals for the observables. (Defining Observable Objectives (p. 2112))

Note

Export and Import of sensitivity data is only required for multi-objective analysis.

---

6. Define constraining and/or deformation conditions on the design change, such as fixed boundaries, prescribed boundary deformation (through a profile, translation, rotation, or scaling), and bounding surfaces / planes. (Defining Conditions for the Deformation (p. 2112))

7. Specify weights for the various objectives, a scaling factor for the deformation, and whether the design conditions are strictly enforced. (Shape Modification (p. 2117))

8. (optional) Adjust the optimal design calculation numerics if required.

9. Compute the optimal design change and modify the mesh.

Details of these steps are elaborated in the following sections:

35.2.5.1. Defining the Region for the Design Change
35.2.5.2. Defining Region Conditions
35.2.5.3. Exporting Sensitivity Data
35.2.5.4. Defining Observable Objectives
35.2.5.5. Defining Conditions for the Deformation
35.2.5.6. Shape Modification
35.2.5.7. Design Tool Numerics

35.2.5.1. Defining the Region for the Design Change

To define the region of space where a design change is to be applied, perform the following steps:

1. Click the **Region** tab of the **Design Tool** dialog box.

2. Make a selection from the **Region Geometry** drop-down to specify whether you will define the space as either a **Cartesian** or a **Cylindrical** region type.

3. For either region type, the **Show Bounding Box** option will be enabled by default; this allows you to view the region associated with the settings along with the mesh in the graphics window.

4. For the Cartesian region type, specify the **X Min**, **X Max**, **Y Min**, and **Y Max** (and **Z Min** and **Z Max** in 3D) fields. Alternatively, the following tools are available:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click the **Get Bounds...** button to open the **Bounding Box Definition** dialog box. There you can select the **Zones to be bounded** from the list of zones, and the fields will be populated to create a bounding box sized to the selected zones.
- Click the **Larger Box** and **Smaller Box** buttons to adjust the deformation region size as needed.

Note

Symmetry conditions affect the location and size of the deformation region:

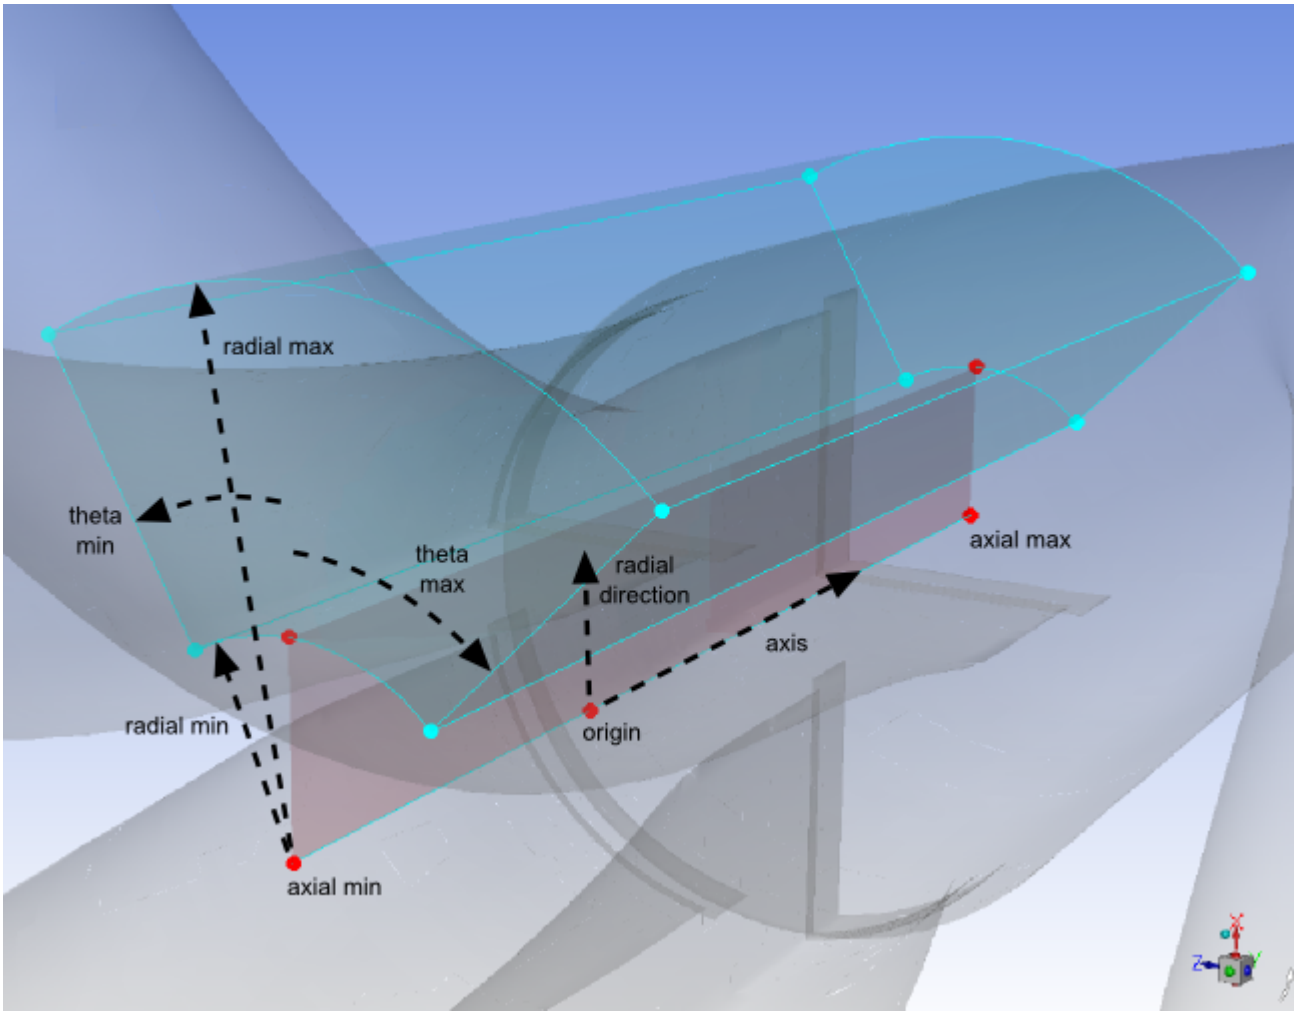
- If you plan to enable the **Symmetry of Motion** options in the **Region Conditions** tab (as described in Defining Region Conditions (p. 2110)), the deformation region should be positioned with forethought given to the effect on the various boundary zones in the region.
- If you have a boundary zone of type **symmetry** in the deformation region, it is recommended that it either is located on a planar boundary of the deformation region, or is centered within the deformation region in a manner that is consistent with the **Symmetry of Motion** option.

---

5. For the cylindrical region type, specify the angular, radial, and (for 3D) axial coordinate ranges; this will require you to define a **Coordinate System**, and then enter the values of the **Region Extent** relative to that system. The fields you will define are illustrated in Figure 35.14: A Cylindrical Region (p. 2110).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.14: A Cylindrical Region



Note the following:

- For 2D cases, the axis is defined implicitly as the Z-axis (as determined by the right-hand rule, where in a front view the X-axis is horizontal and the Y-axis is vertical).
- For the angular range (defined by **Theta Min** and **Theta Max**), the positive direction is determined by the right-hand rule about the axis, and the total range must not exceed 360 degrees.
- For 3D cases, the axis and radial direction must not be co-linear.
- Symmetry conditions affect the location and size of the deformation region, as described in the previous step about Cartesian region types. Note that for a cylindrical region type, radial symmetry is not possible.

6. Click **Update Region**. This will set the values for the region boundaries and update the display of the design change region.

35.2.5.2. Defining Region Conditions

1. Click the **Region Conditions** tab in the **Design Tool** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Specify the control points and motion conditions for each coordinate direction.

   a. Select the number of control **Points**.

      The control points are distributed uniformly within each coordinate range (in the X-, Y-, and Z- directions for a Cartesian region, and the Theta, Radial, and Axial directions for a cylindrical region). The spacing between the control points defines the characteristic spatial scale for the deformation operation. The larger the number of control points, the smaller the spacing and hence, the smaller the spatial scale on which changes can be made. 20 to 40 control points for each coordinate direction is typical.

   b. If you want to prevent deformation of the deformation region in the given coordinate direction, disable **Motion Enabled**.

   c. If you want the motion along a coordinate direction to be uniform in one or more directions, enable the appropriate option (for example, **Invariant in X**).

   d. You can ensure that the deformation is symmetrical relative to the different coordinate directions by enabling options in the **Symmetry of Motion** group box. Symmetry can be imposed in as many directions as desired (though radial symmetry for a cylindrical region is not possible). The symmetry planes will be displayed in the graphics window when you click **Apply**; you should ensure they reflect your intent for the design change, modifying the extents of the deformation region as necessary.

3. The **Region Boundary Continuity** settings control the order of continuity of the deformation process at the boundaries of the deformation region. This is of particular relevance when the boundary of the deformation region intersects a wall that will be deformed. The **Continuity Order** controls the smoothness of the transition from the undeformed wall lying outside the deformation region to the deformed wall within. A value of 1 ensures first-order continuity at the transition, that is, a continuous first derivative of the deformation operation. A value of 2 ensures second-order continuity, and so on.

   By default, the continuity **Definition** is **Uniform** and is enforced at all deformation region boundaries. Alternatively, you can choose **By Boundary** to use different continuity conditions at each boundary. For each boundary (**X-Min**, **X-Max**, and so on) you can specify what order continuity to enforce for each motion direction. You can also specify **In-Plane Motion Only** on that boundary; note that this option may be useful if a deformation region boundary coincides with a boundary zone that is of type **symmetry**.

   The continuity settings will not affect the transition between fixed and movable boundaries within the deformation region, only mesh nodes in the transition zone from inside to outside the deformation region.

4. Click **Apply**.

35.2.5.3. Exporting Sensitivity Data

In order to perform multi-objective optimization, you need to export the sensitivity data for each observable/flow-condition combination that will take part in the optimization.

1. Define the observables of interest as described in Defining Observables (p. 2084).

2. For each observable solve for and export the sensitivity data.

   a. Solve the adjoint as described in Solving the Adjoint (p. 2090).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. In the **Region** tab of the **Design Tool** dialog box, specify the deformation region and click **Export Sensitivities...**.

The exported file contains the sensitivities of the observable for the mesh nodes within the specified deformation region. The deformation regions for the various observables can, in principle, be different. However, it is advisable that there is as much overlap as possible for observables that will be used together in a multi-objective design process.

35.2.5.4. Defining Observable Objectives

The Design Tool computes the optimal mesh deformation to satisfy multiple simultaneous design goals. Among these can be goals for multiple observables, possibly at multiple flow conditions. Once you have obtained the adjoint solutions and displacement sensitivities for the various observables of interest, you can import the data and specify the design objectives for each.

1. Click the **Objectives** tab in the **Design Tool** dialog box.

2. To import previously saved sensitivity data, click **Manage Data...**. In the **Manage Sensitivity Data** dialog box click **Import Sensitivities...** to load previously saved sensitivity files and close the **Manage Sensitivity Data** dialog box.

3. If you want to include computed sensitivity data in the current session that you have not exported yet enable **Include current data**.

4. For each observable objective you can specify the following.

   Objective
   determines how Fluent will attempt to change the value of the observable through the design change. You can choose to increase or decrease the value of the observable optimally, or you can specify a target change in value. You can also select **None** in which case the observable will not be considered in computing the optimal design change, but the predicted change in observable value will still be reported.

   Target/Reference Change
   When the chosen **Objective** is **Target Change in Value**, this field corresponds to the desired change in the value. When the chosen **Objective** is **Maximize** or **Minimize**, the magnitude of this field is a reference weighting for the observable. This can be used to normalize the objectives in cases where you have multiple observables of vastly differing magnitudes, thereby allowing the values entered for **Weight** in the **Design Change** tab to all be of similar scale. You can check **As Percentage** to specify the **Target/Reference Change** as a percentage of the value of the observable.

   Note

   You must click **Apply** for each objective you define before moving on to the next one.

35.2.5.5. Defining Conditions for the Deformation

In the **Design Conditions** tab, you can specify conditions on the mesh morphing such as fixing portions of wall surfaces, prescribing the deformation of surfaces, or setting up bounding planes / surfaces. To create a condition, click **Create...**, select the type of condition in the **Create New Condition** dialog box (you can choose between **fixed-walls**, **bounded-by-plane**, **bounded-by-surfaces**, **prescribed-profile**,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

rotation, **translation**, and **scaling**), and provide a unique **Name**. You can then define the condition by selecting it in the list on the left, defining the settings (as described in the steps that follow), and clicking **Apply**. If necessary, you can **Rename** a selected condition using the **Rename Constraint** dialog box that opens. Once created, the design conditions can be individually included or excluded from the design change in the **Design Change** tab.

Important

Note that a given surface cannot have multiple conditions of type **prescribed-profile**, **rotation**, **translation**, or **scaling**.

Fixed Walls

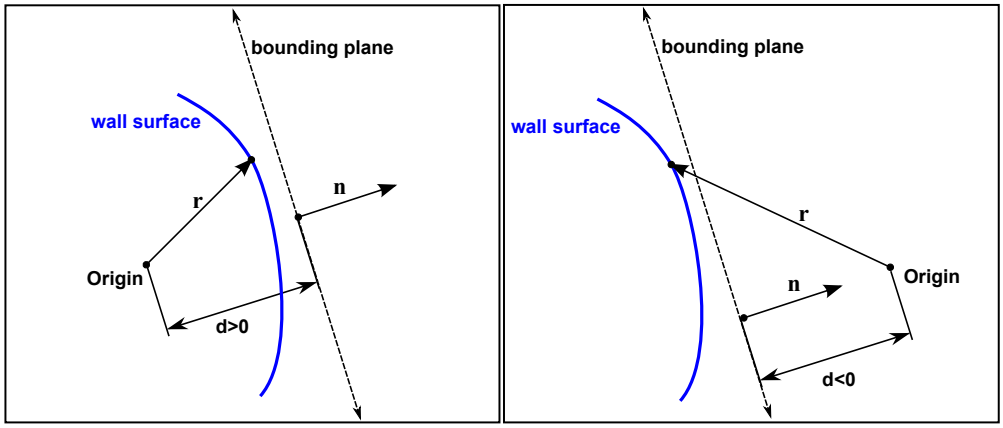
The **fixed-walls** constraint can be applied to clip-surfaces of walls in the deformation region. This offers a fine-grained control over parts of the geometry that should not move. Whereas deselecting a zone in the **Zones To Be Modified** list on the **Design Change** tab will fix an entire wall zone, selecting a clip-surface from in the **Fixed Walls Condition** list will fix only the portion of the wall that forms the clip-surface.

Any clip surfaces you have defined will appear in the **Clip Surfaces** list. You can assign clip surfaces to a fixed walls constraint by selecting them in the list and clicking **Apply**.

Bounding Planes

The **bounded-by-plane** condition allows you to define one or more bounding planes that constrain the geometry deformation in such a way that the geometry cannot cross the given planes, thereby respecting packaging or form-factor constraints. The bounding plane is characterized by a vector normal to the plane and a distance measured from the global coordinate system origin to the plane, along the normal direction. The motion of the selected wall surface(s) will be constrained such that all points on the surface(s) lie on the side of the bounding plane that is opposite to the normal direction.

Figure 35.15: Specifying a Bounding Plane for Design Changes



In Figure 35.15: Specifying a Bounding Plane for Design Changes (p. 2113) the bounding plane normal vector is denoted by $\mathbf{n}$ and the distance is denoted by d. $\mathbf{r}$ is the position vector of a point on the wall surface subject to the bounded-by-plane condition. Note that a positive value for the distance yields a bounding plane that is oriented with its normal pointing away from the origin, while a negative value for the distance yields a bounding plane oriented with its normal direction pointing towards the origin. The constraint equation can be expressed as:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\mathbf{r} \cdot \frac{\mathbf{n}}{|\mathbf{n}|} \leq d$$

1. Select the surfaces (or clip-surfaces) that are subject to the bounding plane condition in the **Bounded Surfaces** list.
2. Enter the components of the bounding plane normal direction.
3. Enter the distance of the plane from the origin (along the normal direction).
4. Click **Apply**.

Bounding Surfaces

The **bounded-by-surfaces** condition allows you to import one or more bounding surfaces that constrain the geometry deformation in such a way that the geometry cannot cross the nearest facet of the bounding surfaces, thereby respecting packaging or form-factor constraints. The bounding surfaces can be read from an `.stl`, `.msh`, or `.cas` file. The deformation of the selected bounded surfaces will be constrained such that all points on the surfaces lie on the sides of the bounding surfaces that have a positive orientation.

1. Select the surfaces (or clip-surfaces) that are subject to the bounded-by-surface condition in the **Bounded Surfaces** list.
2. Use the **Read...** button to import a `.stl`, `.msh`, or `.cas` file that contains the appropriate bounding surface(s). Note that the file you read must have the same dimensionality (2D or 3D) as the working case file.
3. Select the **Imported Surfaces** that will constrain the bounded surfaces.
4. To visually confirm that the selected **Bounded Surfaces** and **Imported Surfaces** are appropriate, click the **Display** button. The imported surfaces will be colored green by default.

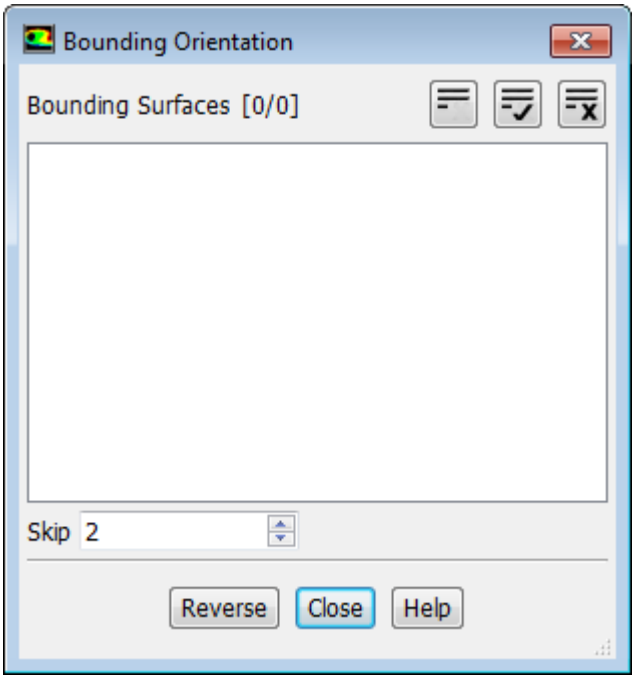
   Note

   When examining the surfaces, it may be helpful to revise display properties of particular surfaces (for example, the color, the level of transparency, and the visibility of the mesh edges or faces). This can be done using the **Scene Description** dialog box, as described in Advanced Scene Composition (p. 1815). Note that you can even revise the display properties of the imported surfaces, the names of which will be displayed with the prefix **bounding-**.

5. To ensure that the **Bounded Surfaces** are constrained on the correct side of the **Imported Surfaces** (that is, the side that has a positive orientation), click the **Orientation...** button. The selected **Imported Surfaces** will be displayed, with their orientation indicated by arrows. In the dialog box that opens (Figure 35.16: The Bounding Orientation Dialog Box (p. 2115)), you can select individual **Bounding Surfaces** and **Reverse** their orientation as necessary; you can also increase the **Skip** value to display less orientation arrows, for cases where the arrow density obscures the orientation. Note that the orientation you define for a particular bounding surface will be used globally for all **bounded-by-surfaces** conditions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.16: The Bounding Orientation Dialog Box



When reviewing the orientation of a bounding surface, you should verify that the facets have a uniform orientation, that is, all of the arrows are on the same side of the surface. Bounding surfaces with facets that have a mixed orientation can affect the convergence and/or accuracy of the calculation.

6. Click **Apply** in the **Design Conditions** tab of the **Design Tool** dialog box to save your settings.

7. If at any point you would like to delete any of the **Imported Surfaces**, you can do so using the Surface Meshes Dialog Box (p. 2807).

Note

When using the **bounded-by-surfaces** condition, it is recommended that you apply preconditioning on the advancement of the process for updating the freeform displacements (by changing the **Preconditioning** field to a positive value in the **Numerics** tab of the **Design Tool** dialog box, as described in Design Tool Numerics (p. 2120)), in order to encourage the stability of the solution. A value on the order of 1 or 10 is recommended.

Prescribed Profiles

You can use the **prescribed-profile** condition to assign a motion profile to a wall zone or zones using a `DEFINE_GRID_MOTION` UDF.

1. Select the wall zones for which to prescribe the displacement in the **Wall Zones** list.

2. Compile your DEFINE_GRID_MOTION UDF in Fluent. (Refer to `DEFINE_GRID_MOTION` in the *Fluent Customization Manual*).

3. Select your UDF in the **Deformation profile** drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Specify the **Scale Factor** to be applied to the deformation profile. Alternatively, you can specify or create an input parameter to use for the **Scale Factor** by clicking the **p** button next to the **Scale Factor** field.

5. Click **Apply**.

Rotation

The **rotation** condition allows you to specify that surfaces undergo rotation.

1. Select the surfaces (or clip-surfaces) you want to rotate in the **Surfaces** list.

2. Enter the rotation **Angle** in degrees. Note that you can enter a set value, or use the P button to assign an input parameter (for example, as part of a parametric study managed by Workbench); see Select Input Parameter Dialog Box (p. 2384) for details.

3. Define the **Origin** about which you want the surfaces to rotate.

4. For 3D cases, define the **Axis** of rotation. For 2D cases, this is automatically defined as the positive Z axis.

5. Click **Apply**.

Translation

The **translation** condition allows you to specify that surfaces undergo translation.

1. Select the surfaces (or clip-surfaces) you want to translate in the **Surfaces** list.

2. Define the **Displacement** to be applied along each coordinate axis. Note that for each field you can enter a set value, or use the P button to assign an input parameter (for example, as part of a parametric study managed by Workbench); see Select Input Parameter Dialog Box (p. 2384) for details.

3. Click **Apply**.

Scaling

The **scaling** condition allows you to specify that surfaces are scaled along one or more axes.

1. Select the surfaces (or clip-surfaces) you want to scale in the **Surfaces** list.

2. Select the scaling **Type** and define the associated settings:

   - **Radial**

     This type scales the surfaces radially about the **Origin**, using a single scaling **Factor** along each of the coordinate axes. The size of the surfaces will change, though not the shape.

   - **In-Plane**

     This type is available for 3D cases, and scales the surfaces about the **Origin** using a single scaling **Factor** along the two axes of a plane (as defined by the **Normal Direction**).

   - **Axial**

     This type scales the surfaces about the **Origin** using a scaling **Factor** along a single **Axis**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **General**

  This type scales the surfaces about the **Origin** using a separate scaling **Factor** for each of the defined axes. For 2D cases, you define one **Axis**, and the second axis is automatically defined as being perpendicular; for 3D cases, you define **Axis 1** and **Axis 2** (which should not be parallel), and the third axis is defined automatically as the cross product. Note that the surfaces will be scaled along each axis sequentially, so the order will be relevant for non-orthogonal axes.

For all types, the scaling **Factor** must be positive. A value of 1 results in no change, while a value greater or less than 1 results in stretching or shrinking, respectively. Note that you can enter a set value, or use the P button to assign an input parameter (for example, as part of a parametric study managed by Workbench); see Select Input Parameter Dialog Box (p. 2384) for details.

3. Click **Apply**.

35.2.5.6. Shape Modification

The procedure for computing the optimal design change and deforming the mesh if as follows:

1. Click the **Design Change** tab.

2. Select those boundaries that are free to be partially constrained or deformed in the **Zones To Be Modified** field. Boundaries that are not selected in this box that intersect the control volume will be constrained not to move. This is useful if there are walls that, for design reasons, must remain fixed and not move.

3. Select the constraining and/or deformation conditions (Defining Conditions for the Deformation (p. 2112)) to be applied to the design change in the list of **Applied Conditions**. Note that a given surface cannot have multiple conditions of type **prescribed-profile**, **rotation**, **translation**, or **scaling**.

4. For each observable, specify its **Weight** in the optimization calculation. The weights are applied to the **Target/Reference Change** you specified in the **Objectives** tab. That is, if you have two observables that are each given a **Weight** equal to 1, Fluent will attempt to find an optimal design change that alters the observable values in proportion to their respective values for **Target/Reference Change.**

   Note

   Weights are only required if there are two or more objectives that do not have explicit target changes specified.

5. Specify the deformation parameters.

   a. Choose a **Freeform Scaling Scheme** and specify the **Freeform Scaling Factor**. This setting controls how the overall scaling factor for the design change magnitude is interpreted.

      Control-point spacing
      The magnitude of the freeform deformation will be based on the control-point spacing. That is, a **Freeform Scale Factor** of `1.0` leads a to maximum control point movement on the order of one sub-cell of the control volume. The sub-cell size is determined by a uniform sub-division of the morphed region based on the number of control points specified (Defining Region Condi-

tions (p. 2110)). A value of `1.0` is a reasonable default to preserve mesh quality during the morphing process.

Objective reference change
The magnitude of the freeform deformation will be based on the **Target/Reference Change** value in the **Objectives** tab. That is, for a single observable optimization with **Freeform Scale Factor** of `1.0`, the design change computed will yield an expected change in the observable equal to the **Target/Reference Change** for the observable.

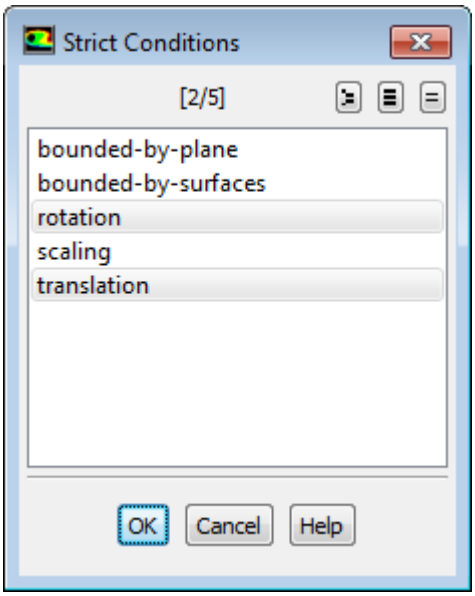
b. If you have disabled **Auto-Select Smoothness** in the **Numerics** tab (Design Tool Numerics (p. 2120)) you can also specify a value for **Smoothness** of the deformed geometry. A lower value will allow locally sharper changes in the geometry, potentially at the expense of manufacturability.

c. If you used an input parameter as part of the setup of a deformation condition in the **Design Conditions** tab, the initial value will be displayed and is available for modification.

6. Click the **Check** button to verify that your constraining and/or deformation conditions are set up in such a way as to produce good results. A report will be printed in the console, summarizing the number of control points defined in the **Region Conditions** tab that are active (that is, not disqualified by other constraints) and listing conflicts between multiple constraints / deformations applied on a single node (including the **Design Conditions** and the continuity constraint applied along the boundary of the morphing region). The conflicts are categorized as being either of type `Fatal` (which indicates the solution is unlikely to converge or be desirable) or `Possible` (which may be allowable, depending on the details of the applied conditions).

7. By default, the condition or conditions specified for a given zone (including the selected **Applied Conditions**, as well as the fixed condition applied to the unselected **Zones To Be Modified**) are not applied to every node, but instead to a subset of nodes distributed throughout the zone; this is to avoid overly constraining the zone. Consequently, some nodes will not strictly adhere to the condition, even if you have defined the constraint tolerance to be small or the residuals are small. To specify that all nodes of the zone strictly obey the condition, click the **Strict Conditions...** button and use the dialog box that opens (Figure 35.17: The Strict Conditions Dialog Box (p. 2118)).

Figure 35.17: The Strict Conditions Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select the conditions for which you want strict enforcement and click **OK**. For unselected conditions, only the default subset of nodes will strictly obey the condition. Note that when you apply strict enforcement to a case in which the **Objective** is **Target Change in Value** (as described in Defining Observable Objectives (p. 2112)), the desired change in the value may not be achieved.

Note

Strict enforcement is a direct modification of the surface mesh nodes to satisfy the design condition, and no modification is applied on the interior mesh. Consequently, when the boundary node modification is large, it may deteriorate the mesh or even cause negative volumes. Therefore you should use this condition carefully: the design condition should reach a good convergence and there should be enough control points.

When you click the **Modify Mesh** button (as described in a later step), the maximum offset for each condition (that is, the maximum distance a node has deviated from the prescribed condition) will be printed to the console.

8. Click **Calculate Design Change** to compute the optimal design change. The **Expected change** for each observable will be reported in the **Design Tool** dialog box.

9. (optional) Click **Write Expected Change...** to write to file the adjustment in the observable that is expected due to the change defined by the current settings.

10. (optional) Click **Export Displacements...** to write to file the optimal surface displacement field (overwriting any pre-existing file of the same name). An example of the format of the text file that is written (for three-dimensions) is as follows:

```
Line 1: n
Lines 2 to n+1: x y z dx dy dz
```

11. The planned change to the geometry can be visualized by plotting the optimal displacement vector field or a contour plot of surface deformation.

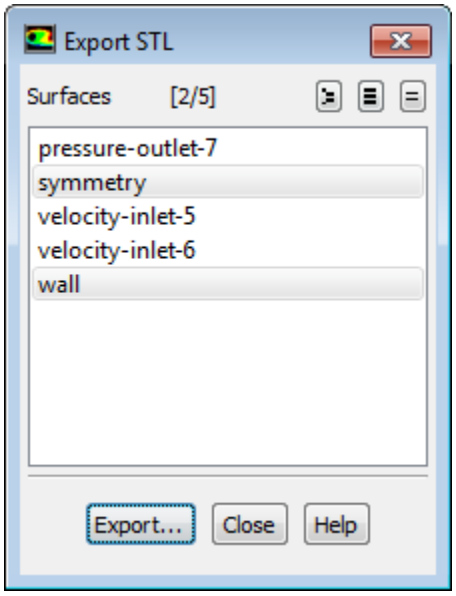
12. Click **Modify Mesh** to deform the boundary and interior mesh with the optimal design change. If you determine that the change is unsatisfactory, you can click **Revert** to undo the mesh changes.

Upon successful modification of the geometry of the system, the modified shape can be viewed using the usual commands for viewing the mesh in ANSYS Fluent. After the mesh has been modified according to the control settings, the original flow calculation can be restarted and converged with the modified geometry. Upon successful convergence, the observable value should now have changed by an amount similar to that reported when the **Expected Change** button was clicked prior to deforming the geometry.

For 3D cases, you have the option of exporting the surfaces from your modified geometry as an `.stl` file, for use in other software packages. Click the **Export STL...** button near the bottom of the **Design Change** tab, select the **Surfaces** of interest in the dialog box that opens (Figure 35.18: The Export STL Dialog Box (p. 2120)) and **Export...** them.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.18: The Export STL Dialog Box



35.2.5.7. Design Tool Numerics

Smoothness

As described in Smoothing and Mesh Morphing (p. 2080), the mesh morphing is controlled by two superposed smoothing bases: the Bernstein polynomial basis which control the large scale smooth deformation and the B-spline basis which controls fine-scale deformation. The choice of smoothness determines the relative weighting of these bases and therefore the spatial scale of the design change. A large value of smoothness biases the design change to one in which optimal displacements vary in space in a manner dominated by the Bernstein polynomial basis. That is, they have a high degree of smoothness. A smaller value of smoothness leads to a recommended design change with smaller spatial scales.

The ability to vary the smoothness parameter is particularly important when prescribed displacements and design conditions are applied. Deformation at smaller spatial scales relieves the stiffness that would otherwise cause numerical challenges as well as lead to poor quality of the computed design and mesh.

By default, Fluent will automatically choose the smoothness. In the Numerics tab, you can disable **Auto-Select Smoothness** in which case a **Smoothness** input will be made available on the **Design Change** tab.

Calculation Numerics

Note

If no **Design Conditions** are imposed, and if there are no walls that are treated as fixed which intersect the region being modified, the numerical settings described below are not used.

In many cases, no adjustment of the detailed numerics will be required for the design tool to compute an optimal solution. However, if the problem under investigation involves many Design Conditions and/or large displacements, the settings may need to be adjusted.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Prescribed Motions

Max. Iterations
The maximum number of inner iterations that will be performed in an effort to compute displacements from prescribed changes.

Constraint Relaxation
The under-relaxation factor that is applied to the field to converge the prescribed displacements. This takes a value between 0 and 1.

Preconditioning
A value of 0 yields the most aggressive advancement, while a larger value encourages more stable, albeit slower, advancement of the process for updating the prescribed displacements. A value of order 1 is typical in the event that preconditioning needs to be applied.

Freeform Motions

Max. Iterations
The maximum number of inner iterations that will be performed in an effort to compute freeform displacements that satisfy the applied **Design Conditions**.

Constraint Relaxation
The under-relaxation factor that is applied to the field to converge the constrained freeform displacements. This takes a value between 0 and 1.

Preconditioning
A value of 0 means that no preconditioning is applied, while a larger value encourages more stable, albeit slower, advancement of the process for updating the freeform displacements. A value of order 1 is typical in the event that preconditioning needs to be applied.

Parameter Relaxation
For design conditions such as the Bounded-By-Plane condition there are additional parameters that are implicit in the calculation. The values of these parameters are computed as part of the solution process. The value of the parameter relaxation defines the rate at which these parameters are corrected as the calculation progresses. This takes a value between 0 and 1.

Tolerances

Constraints
The tolerance for convergence of the residuals associated with the design conditions themselves, or fixed zone conditions.

Parameters
The tolerance for convergence of the parameters associated with the design conditions.

Using a value of 1 for **Constraint Relaxation** and a value of 0 for **Preconditiong** yields the most aggressive behavior. This can result in the fewest number of iterations to converge a constrained problem, at the expense of some added numerical effort and memory in preparing the preconditioning. For 2D and small 3D problems the added cost in time and memory is typically small. For larger problems involving multiple constraints a non-zero **Preconditioning** and **Constraint Relaxation** less than 1 may be preferable. The execution time to set up the preconditioning will be less, as will the memory usage. Calculation stability can also be improved. The number of iterations required to converge the problem will increase. However, this can prove to be an effective strategy that results in an overall shorter time needed to compute the design change.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

35.3. The Mesh Morpher/Optimizer

The mesh morpher/optimizer offers a variety of non-gradient-based optimization algorithms to optimize the geometric shape of a system [47] (p. 2889). The optimization can be performed for a wide variety of physics and quantities of interest to be optimized.

For additional information, see the following sections:

35.3.1. Limitations
35.3.2. The Optimization Process
35.3.3. Optimizers

35.3.1. Limitations

Note the following limitations of the ANSYS Fluent mesh morpher/optimizer:

- The mesh morpher/optimizer should not be used with dynamic or sliding mesh problems.
- Any geometrically evaluated parameters required for flow iterations (for example, view factors for the surface to surface (S2S) radiation model) will need to be recomputed at the very least when the optimization is complete. If the objective function is affected by one of these geometrically evaluated parameters, then such parameters will need to be recomputed after each design change; for example, the view factors need to be recomputed after each design change when the objective function is a function of temperature.
- Arbitrarily shaped deformation regions are not supported.

35.3.2. The Optimization Process

All optimization problems require that you identify parameters that can be modified in order to reach the optimized solution. In the case of the mesh morpher/optimizer, it is the geometry that must be parameterized. Geometric parameterization for general shapes used in CFD can be very complicated, due to the large variety of shapes available in engineering applications. In order to minimize such complications in your ANSYS Fluent simulation, the problem of shape parameterization is reduced to a problem of the parameterization of changes in the geometry.

The next essential requirement for mesh morphing is a tool that can smoothly alter the shape, irrespective of the underlying mesh topology. In ANSYS Fluent, designated deformation regions are manipulated via displacements applied to a set of control points. The mesh region that is to be deformed is defined by a "box" (that is, a rectangle for 2D cases and a rectangular hexahedron for 3D), and the control points must be located within the box. The displacements of the control points are the result of user-defined motions (each of which involves a parameter value and other directional settings) and these displacements are then applied to the mesh as a smooth deformation by either interpolating the displacement based on radial basis functions or using the tensor product of Bernstein polynomials.

The next requirement is to have an optimizer that is robust enough to handle a wide range of problems. By coupling such optimizers with your CFD analysis, you can greatly improve your design with minimal intervention. You can use built-in optimizers to vary the parameter values along the prescribed directions and within defined bounds, in order to satisfy a condition specified by an objective function. The mesh morpher/optimizer provides you with access to six optimizers that are not based on gradients. Otherwise, you can manually specify the deformation (that is, define both the parameter values and the directions) and analyze the results; you also have the option of using Design Exploration in ANSYS Workbench to easily explore the impact of a variety of parameter values.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

35.3.3. Optimizers

The built-in optimizers used as part of the mesh morpher/optimizer capability in ANSYS Fluent use direct search methods for optimization. Direct search methods are zeroth order, as they only use the objective function values for optimization. The direct search methods do not use the derivatives.

The following is a list of advantages of direct search methods:

- Direct search methods do not require derivatives for optimization.
- Direct search methods are robust for problems with discontinuities and in situations where the derivative computation is not possible or unreliable.

The following is a list of disadvantages of direct search methods:

- Convergence proof is not clearly defined.
- The rate of convergence can be very slow.

General explanations of the six different built-in optimizers are provided in the following sections:

35.3.3.1. The Compass Optimizer
35.3.3.2. The NEWUOA Optimizer
35.3.3.3. The Simplex Optimizer
35.3.3.4. The Torczon Optimizer
35.3.3.5. The Powell Optimizer
35.3.3.6. The Rosenbrock Optimizer

35.3.3.1. The Compass Optimizer

In the Compass optimizer [53] (p. 2889), the parameters are adjusted one by one until the objective function is minimized. This optimizer starts with a given value and then evaluates the function value in all the basic directions. The direction here refers to the positive and negative increments to the initial parameter values. If there is a reduction in the function value, then that point becomes an improved point. If there is no improvement in the function values, then the step length is reduced by half and the search is repeated in all directions. The algorithm terminates when the step size falls below a certain tolerance.

The Compass optimizer initially makes rapid progress towards the solution. While this method might quickly approach the minimum value of an objective function, it may be slow to detect this fact. It may also converge very slowly if the level sets of the objective function are extremely elongated.

35.3.3.2. The NEWUOA Optimizer

The NEW Unconstrained Optimization Algorithm (NEWUOA) optimizer [89] (p. 2891) attempts to find the least value of a function $F(x)$, where x is a parameter vector of n dimensions. At the start of every iterative step, a quadratic model approximation ($Q \sim F$) is constructed and the minimization is performed on a trust region (that is, a region around the parameter that is limited by an initial parameter variation). The perturbation to the parameter value needed to obtain the lowest value of Q is evaluated during the iteration, and correspondingly, the new least value of $F(x)$ is obtained. The iterative process continues until the trust region is reduced to the optimizer convergence criterion, and the optimizer exits with the least value of the objective function. This optimization algorithm can be applied to any setup case of the mesh morpher/optimizer.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The NEWUOA optimizer provides the least value of the objective function in a manner that is highly accurate and robust. The main advantage of this optimizer is that it is very fast; hence, this optimizer is recommended for problems that have a large number of parameters.

35.3.3.3. The Simplex Optimizer

The Simplex optimizer is also referred to as the Downhill Simplex optimizer [68] (p. 2890), [47] (p. 2889) and the Nelder-Mead method [74] (p. 2891). It is based on the idea of geometric simplexes; for example, a 2D simplex is a triangle, and a 3D simplex is a tetrahedron.

For optimization purposes, ANSYS Fluent requires that simplexes are regular polyhedra (that is, not degenerate polyhedra with collapsed sides). Each vertex of the geometric simplex represents one function evaluation (which in this case is one CFD run), and the number of vertices corresponds to the number of parameters. For the free-form deformation method that is used by ANSYS Fluent to parameterize changes in shapes, the number of active control points will determine the number of vertices of the geometric simplex.

Minimization of the objective function is performed based on a set of the rules about the "quality" of each vertex. The vertex quality is the value of the function evaluated for each position of the control point. A set of geometric operations such as reflection, expansion, contraction, and shrinking are performed in order to find the region in which to look for the minimum of the function. Because optimization here is formulated as a minimization problem, the simplex optimizer algorithm seeks the "worst" vertex, that is, the vertex that has the largest value when the corresponding parameter is evaluated. By performing the reflection around the center of the gravity, the new value of the function is obtained after performing the CFD run. Similarly, the operations of expansion, contraction, and shrinking are used to obtain the minimum of the function.

The Simplex optimizer is known to work well, but it suffers from the large number of function evaluations. It also requires smooth objective functions for convergence.

35.3.3.4. The Torczon Optimizer

The Torczon optimizer [125] (p. 2893) is a slightly modified version of the simplex optimizer described previously. Given an initial vertex, this optimizer tries to find a better vertex that has a function value that is strictly less than the function value at the previous best vertex. There are three possible trial steps: the rotation step, the expansion step, and the contraction step. The algorithm always computes the rotation step and then tests to see if a new best vertex has been identified. If it has, then the expansion step is computed. Otherwise, the algorithm computes and automatically accepts the contraction step.

35.3.3.5. The Powell Optimizer

For the Powell optimizer, the method used is based on the number of dimensions of the problem. For optimization problems of single dimension (that is, problems with a single parameter), the golden section search algorithm [90] (p. 2891) is used to find the optimal value for the objective function. In this algorithm, the optimal value is found by reducing the size of the bracketing triplet, until the size of the bracket (that is, the distance between the outer points of the triplet) reaches a certain tolerance level. In all the cases, the middle point of the new triplet is determined to be the best value obtained so far.

For multidimensional problems (that is, problems with multiple parameters), the minimum value and the largest decrease is found using the golden search algorithm for each dimension, in order to find the conjugate directions. A conjugate direction is a direction that when searched will not alter the minimum value attained by the previous movement in another direction—that is, a direction in which

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the gradient is perpendicular to the first direction. After finding the N linearly independent, mutually conjugate directions, one pass will find the exact minimum value. For functions that are not quadratic, repeated cycles of N line minimizations will converge to minimum.

35.3.3.6. The Rosenbrock Optimizer

In the Rosenbrock optimizer [96] (p. 2892), after the initial direction is found, multiple steps are taken in that direction until the least value is attained. The process starts with an arbitrary length e. If this initial step succeeds (that is, the new value of the function is less than or equal to the old value), the length e is multiplied by α, where α is more than 1. If the steps fails, the length e is multiplied by β, where β is between -1 and 0. The direction or the parameter that must be modified is determined by advancing all the parameters by the step length e and then selecting the best among those that yield a function value that is less than the previous value. After that point is accepted as the best point, the process is repeated. These steps continue to repeat until e becomes so small so that any further change in the value of e does not significantly reduce the value of the function.

35.4. Using the Mesh Morpher/Optimizer

The procedure for setting up and using the mesh morpher/optimizer for shape optimization is as follows:

1. Read the case into ANSYS Fluent.

   File → **Read** → **Case...**

2. If you want to use one of the built-in optimizers rather than specifying the deformation manually or using Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, you will need to provide an objective function in one of three ways: either as a user-defined function (UDF), a Scheme source file, or a customized function that is based on output parameters (that is, values from flux, force, surface integral, or volume integral reports). The goal of the optimizer is to deform the mesh in such a way that this objective function is minimized. ANSYS Fluent will run the solution for a given design stage until convergence is reached, and then check to see if the objective function is satisfied. If the objective function is not satisfied, ANSYS Fluent will proceed to the next design, and so on, until convergence is achieved from the point of view of the optimizer. You can specify the optimizer convergence criteria in step 12.d.iii.

   Note that if you plan to use the **newuoa** optimizer, you must define the objective function as a UDF.

   a. If you want to provide the objective function as a user-defined function (UDF), perform the steps that follow. For more information about UDFs, see the separate Fluent Customization Manual.

      i. Write a UDF using the `DEFINE_ON_DEMAND` macro to define the objective function. The function name must be `objective_function`. At the end of the objective function, the rpvar `morpher/objective_function` must be set to the `(current - target)` value. It is this value that the optimizer will attempt to minimize.

      ii. Compile the UDF using the **Compiled UDFs** dialog box. Make sure `libudf` appears as the **Library Name**.

      User Defined → **User Defined** → **Functions** → **Compiled...**

   b. If you want to provide the objective function as a Scheme source file, perform the following steps:

i. Write a Scheme source file to define the objective function. The procedure name must be `objective-function`. At the end of the objective function, the rpvar `morpher/objective-function` must be set to the `(current - target)` value. It is this value that the optimizer will attempt to minimize.

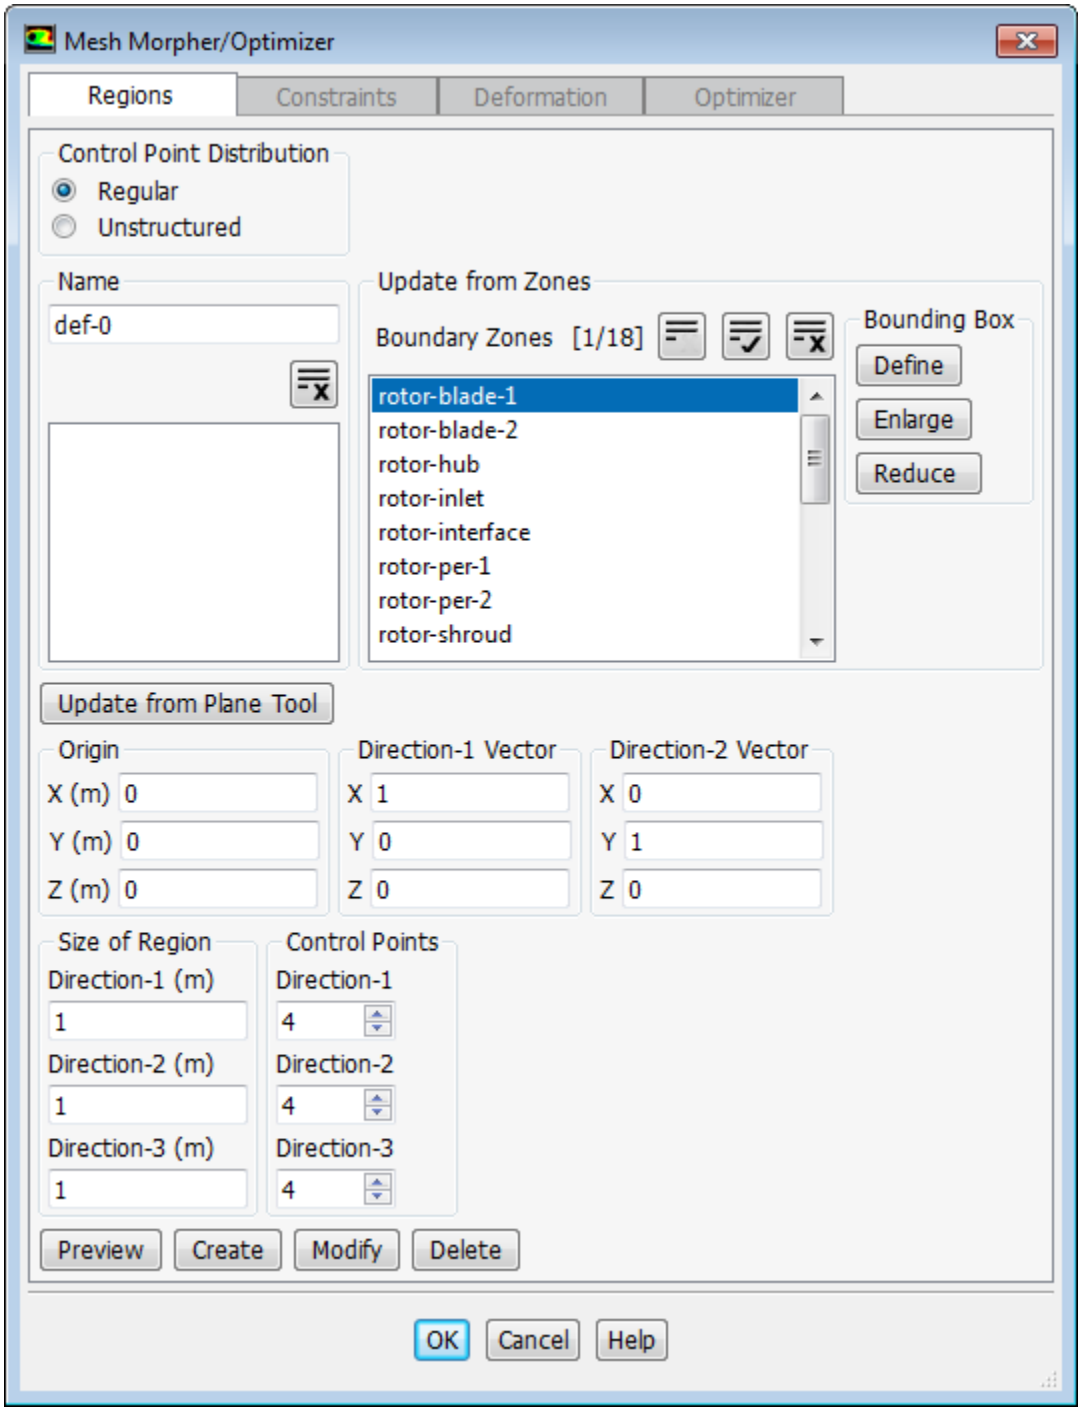
ii. Load the Scheme source file (see Reading Scheme Source Files (p. 57) for details).

3. Open the **Mesh Morpher/Optimizer** dialog box by clicking **Optimizer...** in the **Design** ribbon tab (**Parameter-Based** group box).

   The first time you click **Optimizer...** in a session, a question dialog box will ask you whether you want to enable the mesh morpher/optimizer. Click **Yes** to load the libraries and open the **Mesh Morpher/Optimizer** dialog box (Figure 35.19: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2127)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.19: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box



4. Specify the manner in which you would like to define the locations of the control points, by making a selection from the **Control Point Distribution** list in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box (Figure 35.19: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2127) and Figure 35.20: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box for an Unstructured Distribution (p. 2129)). Your selection here will also determine the kinds of motions you can apply to the control points (in the **Deformation** tab). You have the following choices:

   - **Regular**

For this option, the control points are spread in a regular distribution throughout the entire deformation region; you only have to define the number of control points along each of the defining direction vectors. Note that as part of this option, the motion of groups of control points will have to be defined as a translation, as the ability to define rotational or radial motions is not available.

Locating control points in this manner is easy and simple, though this comes at the cost of being able to precisely define control points on specific mesh nodes and boundaries. This option can be a good choice in cases where you are able to allow the entire mesh within the region to be deformed—for example, internal flows within a pipe or duct.

Note that as part of this option, the mesh deformation is based on Bernstein polynomials. While such a direct morphing approach is computationally less expensive than using radial basis functions, it does not provide you with precise control of a particular mesh node.

- **Unstructured**

  For this option, you will define the locations of the control point by right-clicking with the mouse on boundary zones, distributing an approximate number throughout a zone, or by entering coordinates. Note that as part of this option, the motion of groups of control points can be defined as a translation, as a rotation about a point / axis, or radially about a point / axis.

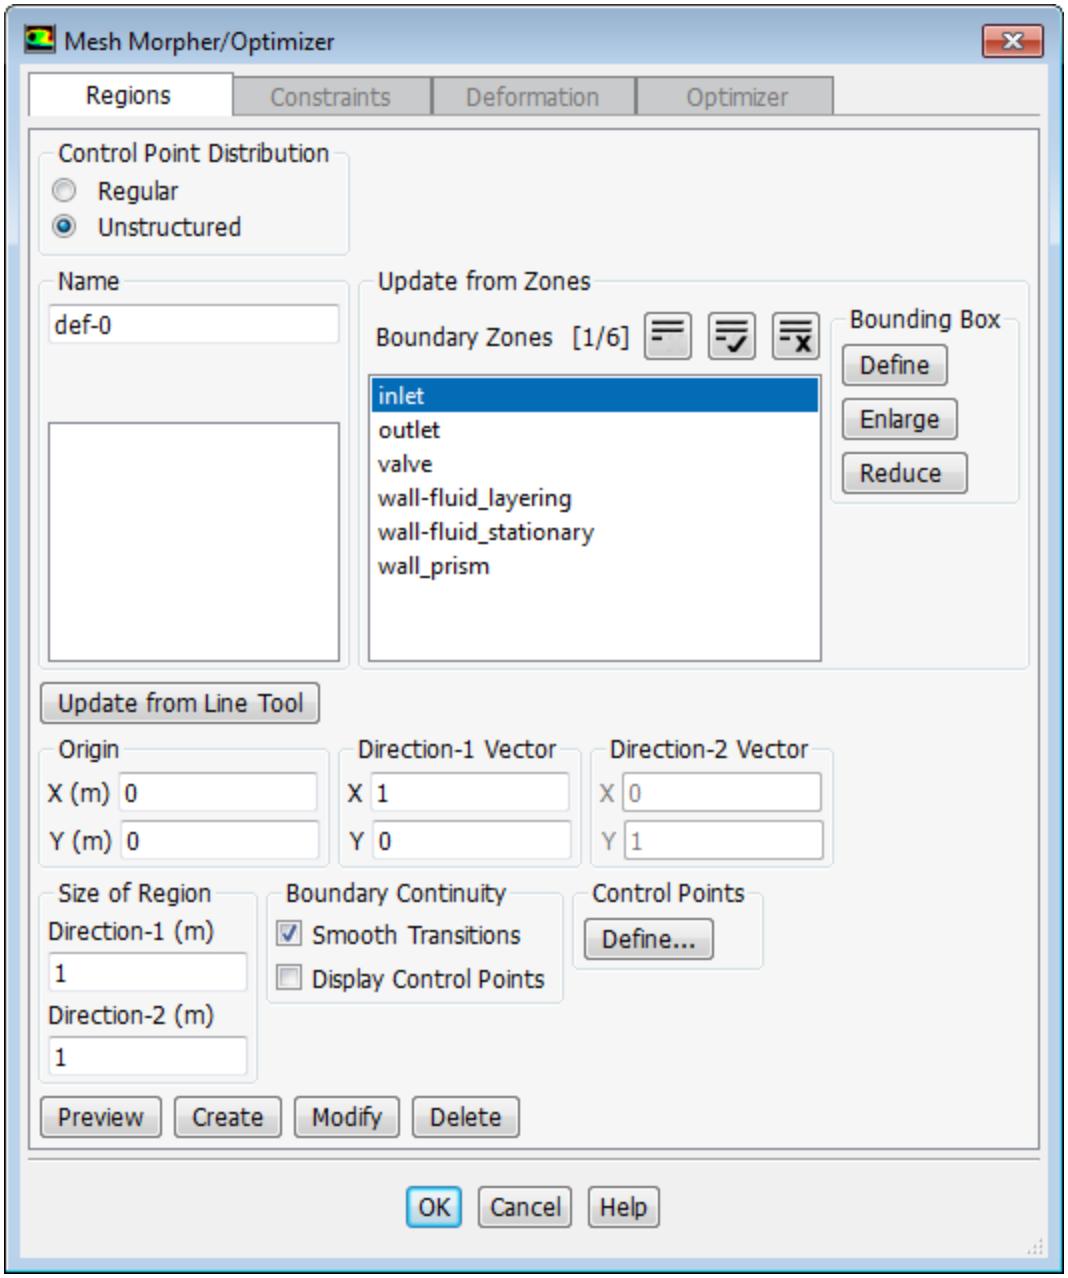
  This option provides great precision with regard to the location of the control points; this allows you to morph particular nodes and regions of the mesh, as well as to preserve features within the deformation region (as you can make nodes stationary by applying a parameter value of zero). This option also allows you to easily define twisting and axisymmetrical motions. This may be a good choice for external flows and aerodynamic applications.

  Note that as part of this option, the mesh deformation is based on radial basis functions. While this is computationally more expensive than using Bernstein polynomials (because it involves the solution of a system of equations), it allows you to have precise control of a particular mesh node if you have created a control point with the same coordinates.

Note that all of the deformation regions that you define in the next step must use the same **Control Point Distribution**; if you change this selection at any point, all of the settings in the **Regions** tab will be deleted.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.20: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box for an Unstructured Distribution



5. Define the region(s) of the domain where the mesh will be deformed in order to optimize the shape, by performing the following steps. Each deformation region will be defined as a "box", that is, a rectangle for 2D cases and a rectangular hexahedron for 3D cases.

Important

It is recommended that you define each deformation region to be bigger than the area of interest, in order to maintain proper continuity between deforming and non-deforming regions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. In the **Regions** tab, enter a name for a deformation region in the text-entry box at the top of the **Name** group box.

b. You have the option of using the boundary zones to create a bounding box for the deformation region; this box can represent the final scope of the region, or it can act as a starting point that is further refined by manually editing the origin, direction vectors, and size of the region (as described in the steps that follow). Perform the following steps in the **Update from Zones** group box:

   i. Select the zones from the **Boundary Zones** list that best represent the extents of the deformation region you would like to create.

   ii. Click the **Define** button in the **Bounding Box** group box to update the values in the **Origin**, **Direction-1 Vector**, **Direction-2 Vector** (for 3D cases), and **Size of Region** group boxes. Note that the bounding box will be previewed in green in the graphics window when you click any of the **Bounding Box** buttons.

   iii. You can increase or decrease the size of the bounding box by clicking the **Enlarge** and **Reduce** buttons, respectively. Note that you have the option of setting the scaling factors associated with these buttons via the following text commands:

   `define` → `mesh-morpher-optimizer` → `region` → `scaling-enlarge`

   `define` → `mesh-morpher-optimizer` → `region` → `scaling-reduce`

c. You have the option of using the line tool (for 2D cases) or the plane tool (for 3D cases) to define the direction vectors of the deformation region; the values defined can represent the final components of the vectors, or they can act as a starting point that is further refined by manually editing the direction vectors (as described in the steps that follow). Set up the line tool or the plane tool (as described in Using the Line Tool (p. 1720) and Using the Plane Tool (p. 1724), respectively), and then click the **Update from Line Tool** or **Update from Plane Tool** button to update the values in the **Direction-1 Vector** and (for 3D cases) **Direction-2 Vector** group boxes.

d. Define an origin for the deformation region by entering the Cartesian coordinates of a point in the **X**, **Y**, and (for 3D) **Z** number-entry boxes in the **Origin** group box. Note that as you enter values, you can view the resulting bounding box (in green) by clicking the **Preview** button.

e. Define the first direction vector of the deformation region relative to the **Origin** coordinates, by entering values in the **X**, **Y**, and (for 3D) **Z** number-entry boxes in the **Direction-1 Vector** group box.

   For 2D cases, ANSYS Fluent will automatically define the second direction vector of the deformation region to be perpendicular to the **Direction-1 Vector**, and will display the components in the uneditable **Direction-2 Vector** group box.

f. For 3D cases, define the second direction vector of the deformation region relative to the **Origin** coordinates, by entering values in the **X**, **Y**, and **Z** number-entry boxes in the **Direction-2 Vector** group box. If the vector you define is not perpendicular to the **Direction-1 Vector**, ANSYS Fluent will automatically redefine the second vector to be the projection of the **Direction-2 Vector** you entered onto a plane that is perpendicular to the **Direction-1 Vector**. Based on this definition, the **Direction-2 Vector** you define cannot be colinear with the **Direction-1 Vector**.

   The third direction vector of the deformation region will be automatically defined as the cross product of the first and second direction vectors.

g. Define the overall dimensions of the deformation region by entering length values for **Direction-1**, **Direction-2**, and (for 3D cases) **Direction-3** in the **Size of Region** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

h. Create control points within the deformation region.

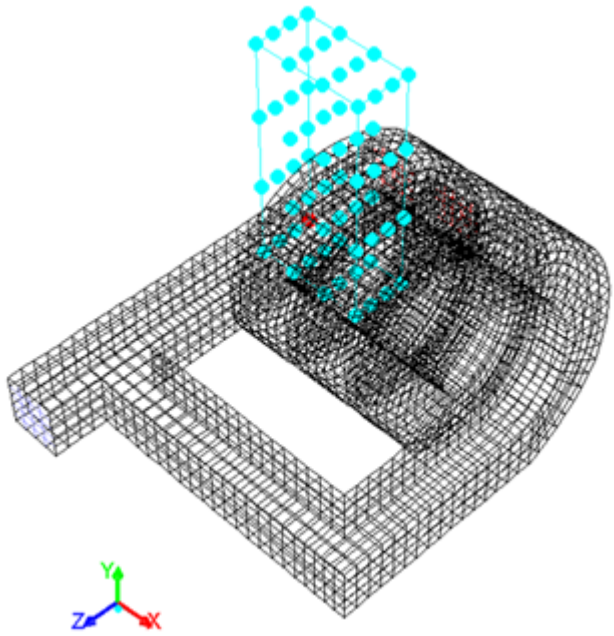
i. If you selected **Regular** for the **Control Point Distribution**, define the number of control points you want along each direction vector of the deformation region by entering values for **Direction-1**, **Direction-2**, and (for 3D cases) **Direction-3** in the **Control Points** group box. The total number of control points for the region will be the product of the numbers you enter. Increasing the number of control points allows you greater control of the deformation, but also increases the computational expense.

Important

When you define multiple deformation regions, you must ensure that all the deformation regions have the same total number of control points.

Save the settings you have created for the deformation region by clicking the **Create** button. The name of the deformation region will be added (and selected) in the selection list at the bottom of the **Name** group box, and the control points and bounding box of the deformation region will be displayed in blue in the graphics window (see Figure 35.21: Displaying the Control Points for a Regular Distribution (p. 2131)). If you do not want the control points and bounding box displayed in the graphics window, you can deselect the item by clicking the button located above the right side of the **Name** selection list.

Figure 35.21: Displaying the Control Points for a Regular Distribution



A new default name will be automatically entered in the text-entry box at the top of the **Name** group box, in preparation for any deformation regions you want to create in the future.

ii. If you selected **Unstructured** for the **Control Point Distribution**, click the **Create** button to save the settings for the deformation region, as you need an existing region to be able to create control points. The name of the deformation region will be added (and selected) in the selection list at the bottom of the **Name** group box, and the bounding box will be displayed in blue in the graphics window (see Figure 35.23: Displaying the Control Points for an Unstructured Distribution (p. 2134)).

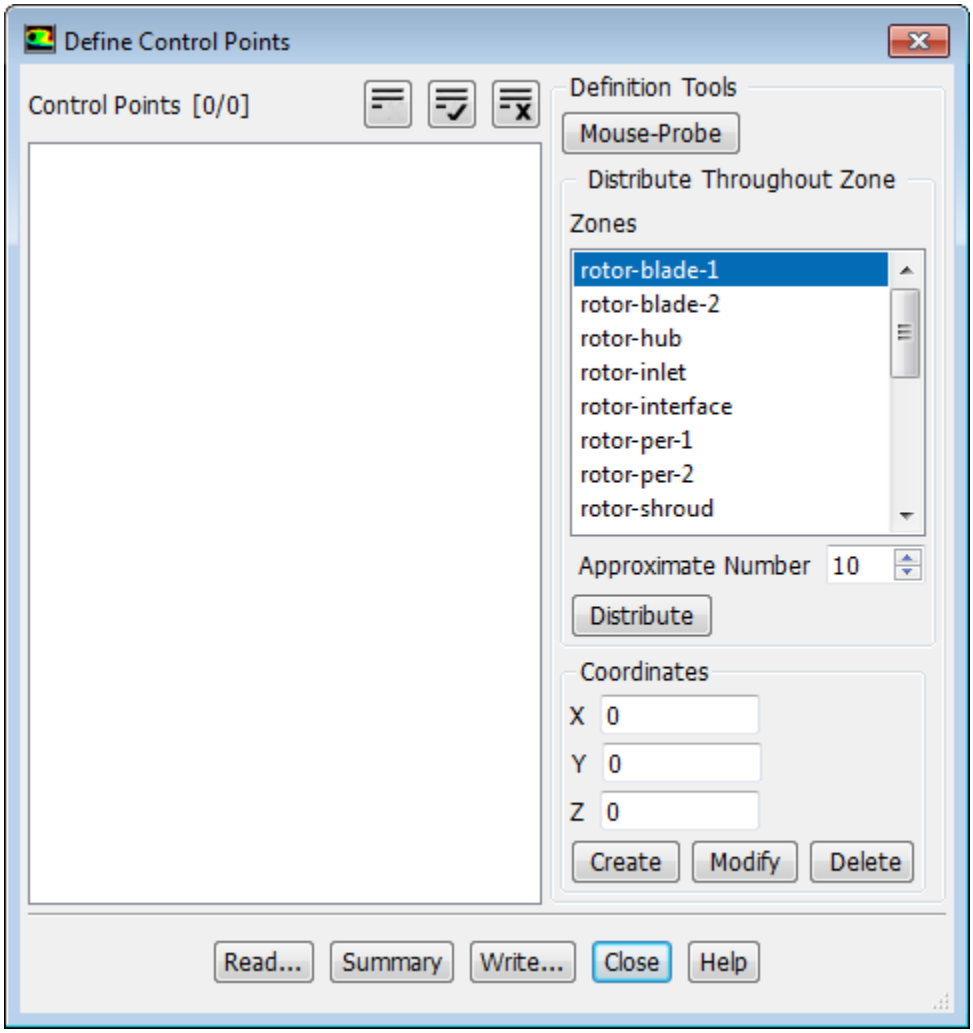
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If at any point you do not want the bounding box displayed in the graphics window, you can deselect the item by clicking the button located above the right side of the **Name** selection list.

Next, examine the settings in the **Boundary Continuity** group box. By default, the mesh morpher/optimizer is set to provide smooth mesh transitions wherever the mesh intersects with the limits of the deformation region (that is, the sides of the bounding box). This is accomplished through the creation of stationary control points at those intersections; by default, these control points are hidden, though you can view them by enabling the **Display Control Points** option. If you would like to allow more abrupt mesh transitions at the boundaries of the region, you can disable the **Smooth Transitions** option.

The next step is to create control points. Click the **Define...** button in the **Control Points** group box to open the **Define Control Points** dialog box (Figure 35.22: The Define Control Points Dialog Box (p. 2132)).

Figure 35.22: The Define Control Points Dialog Box



Use the **Define Control Points** dialog box to create control points within the region. You have the following options:

- Click the **Mouse-Probe** button and then probe (using the right mouse button, by default) within the deformation region. For 3D cases, if you probe on a displayed boundary, the control point

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will be located at that point on that boundary. Note that it may be helpful to revise what surfaces are displayed using the Mesh Display Dialog Box (p. 2163).

- Make a selection from the **Zones** list, enter an **Approximate Number** of control points that you want on that zone, and click the **Distribute** button. This method uses Binary Space Partitioning (BSP) to agglomerate the cell faces of the zone within the bounding box based on the intended number of control points, and then a control point is assigned to the node that is closest to the centroid of each agglomeration. While this method is convenient when you want a large number of control points or want to morph entire boundary zones or surfaces, there are some limitations to BSP: the number of control points may exceed the value you enter, and the control points will not be as evenly distributed on curved surfaces when compared to flat surfaces.

- Enter **X**, **Y**, and **Z** coordinates and click the **Create** button. This method allows you to locate a control point directly on a mesh node, if you have first obtained the vertex position (which can be displayed in the console if you select **long description** from the **Probe** drop-down list in the **Viewing** tab (**Mouse** group box) and then probe near the node with the mouse).

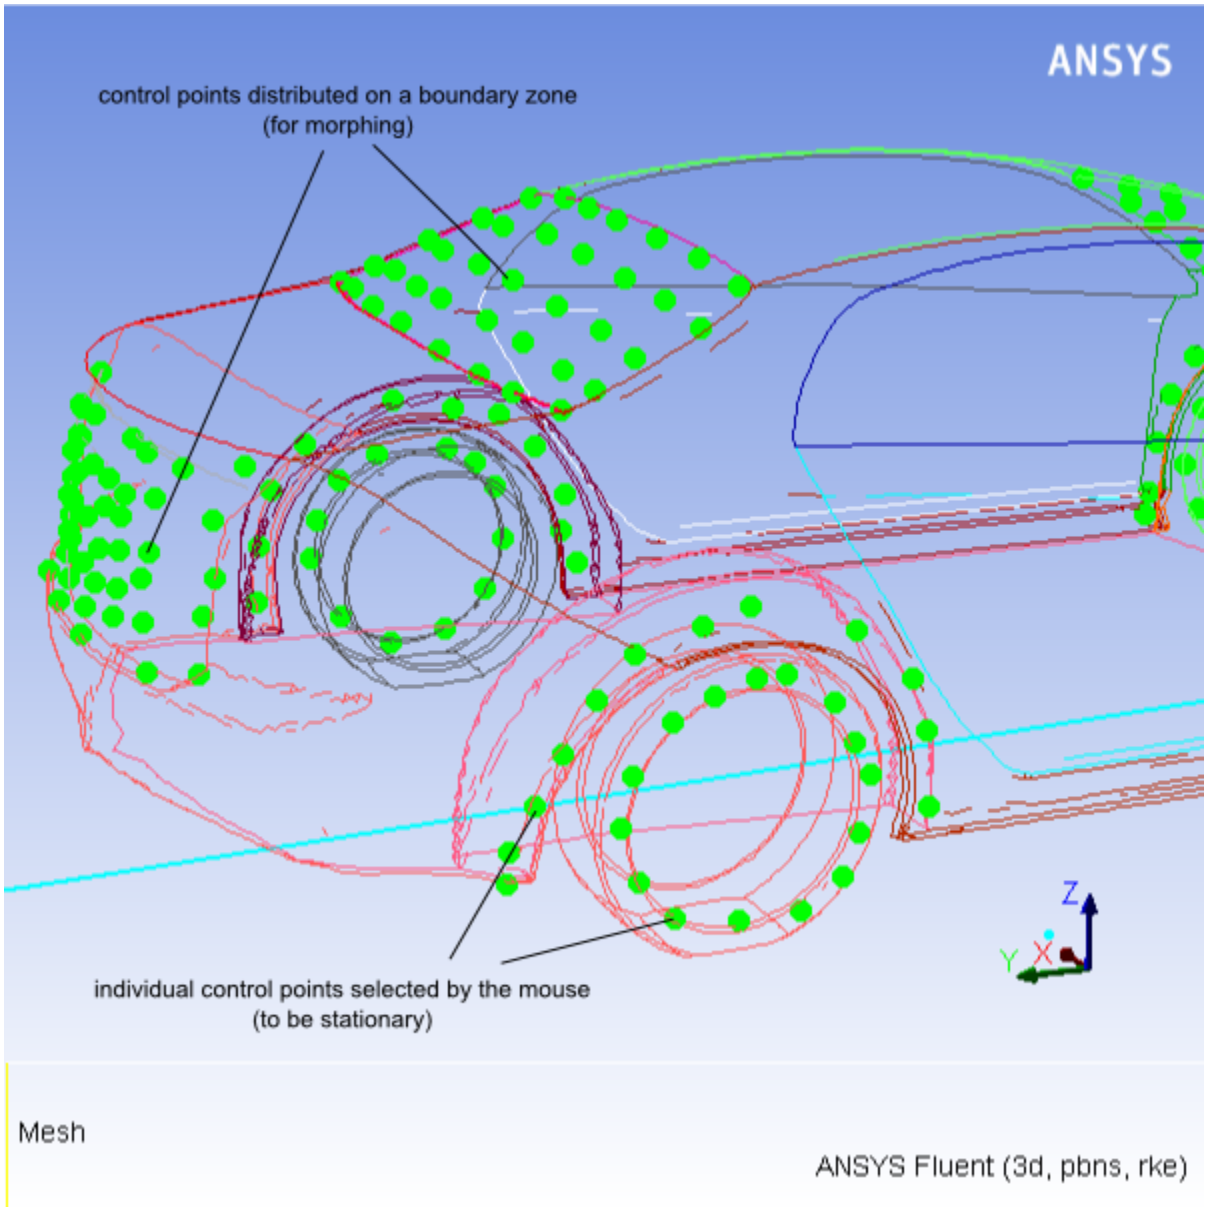
- If you have previously generated an ASCII text file that contains control point definitions, you can read it by clicking **Read...** and using the dialog box that opens. Using a text file can be helpful when you have a large number of points. It is not necessary to create the text file from scratch, as you can create a simplified text file with sample data using the **Write...** button, and then define the bulk of the control point locations using a spreadsheet program. See Mesh Morpher/Optimizer File Formats (p. 2867) for details about the format of the text file.

The control points will be displayed in green in the graphics window, and will turn red when selected in the **Control Points** selection list. When a control point is selected, you also have the ability to **Delete** it, or enter new coordinates and **Modify** it.

When adding control points, remember that it may be helpful to locate them not only in areas that you want to deform, but also on features in the deformation region that you want to preserve (as you can make nodes stationary by applying a parameter value of zero). When you are done adding control points, click **OK** to close the **Define Control Points** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.23: Displaying the Control Points for an Unstructured Distribution



A new default name will be automatically entered in the text-entry box at the top of the **Name** group box, in preparation for any deformation regions you want to create in the future.

i. Create any additional deformation regions as necessary by repeating steps 5.a.–h.

Important

Overlapping deformation regions are not supported.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

j. If you need to modify a deformation region at any point, select it in the **Name** selection list, revise the appropriate settings, and click the **Modify** button. The updated control points and bounding box will be displayed in the graphics window.

> **Important**
>
> When modifying an existing deformation region, be sure to click **Modify** rather than **Create**. If you click **Create**, you will not modify the deformation region, but will instead create a new one with the modified settings.

k. If you need to delete a deformation region at any point, select it in the **Name** selection list and click the **Delete** button.

6. You have the option of defining constraints on the boundary zones, in order to limit the freedom of particular zones that fall within the deformation region(s) during the morphing of the mesh. The following options are available:

- unconstrained

  This option specifies that the boundary zone is completely free to be deformed according to the assigned parameters. By default, all wall zones are unconstrained.

- fixed

  This option specifies that the boundary zone is fixed and will not be deformed. None of the zones are fixed by default.

> **Important**
>
> If you specify one or more fixed boundary zones in a deformation region, you must ensure that there is at least one unconstrained boundary zone in the region as well.

- passive

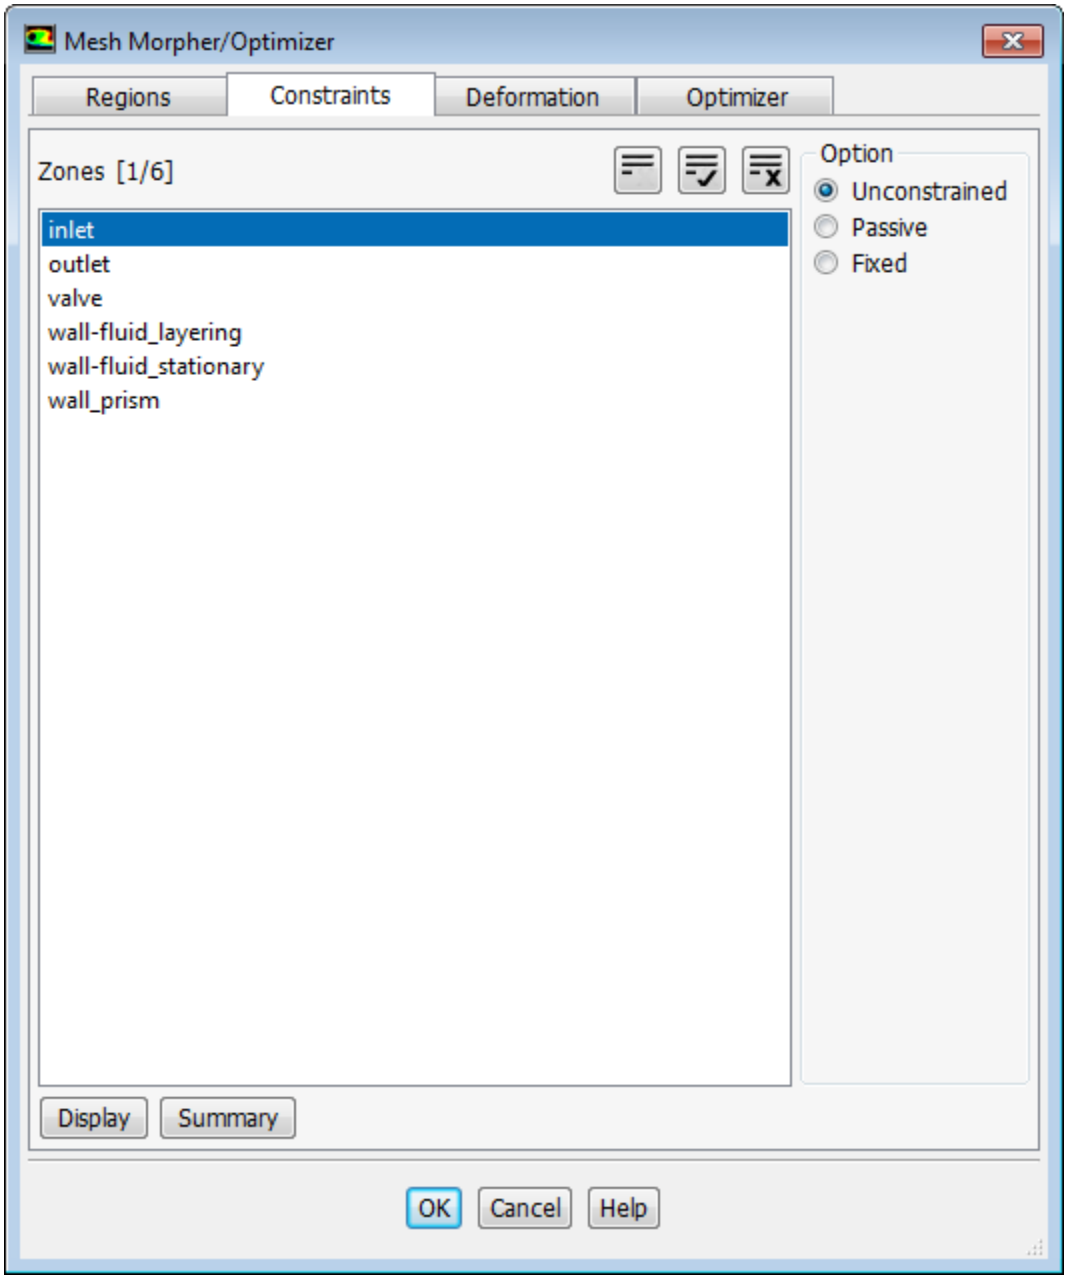
  This option specifies that the nodes of the boundary zone are partially constrained to varying degrees, based on their proximity to adjacent boundary zones that are fixed. The nodes in a passive boundary zone behave in a similar manner to the interior mesh nodes, in order to ensure that there is a smooth transition between fixed and unconstrained boundary zones. By default, all boundary zones that are not walls (for example, inlets, outlets, symmetry, and periodic boundaries) are passive.

To define the constraints on the boundary zones, perform the following steps.

a. Click the **Constraints** tab (Figure 35.24: The Constraints Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2136)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.24: The Constraints Tab of the Mesh Morpher/Optimizer Dialog Box



b. To revise the default constraints on the boundary zones, select the zone name(s) from the **Zones** selection list in the **Constraints** group box, and then select either **Unconstrained**, **Passive**, or **Fixed** from the **Option** list.

c. Click **Display** if you want view the boundary zones selected from the **Zones** selection list, in order to verify the zones for which you are defining constraints.

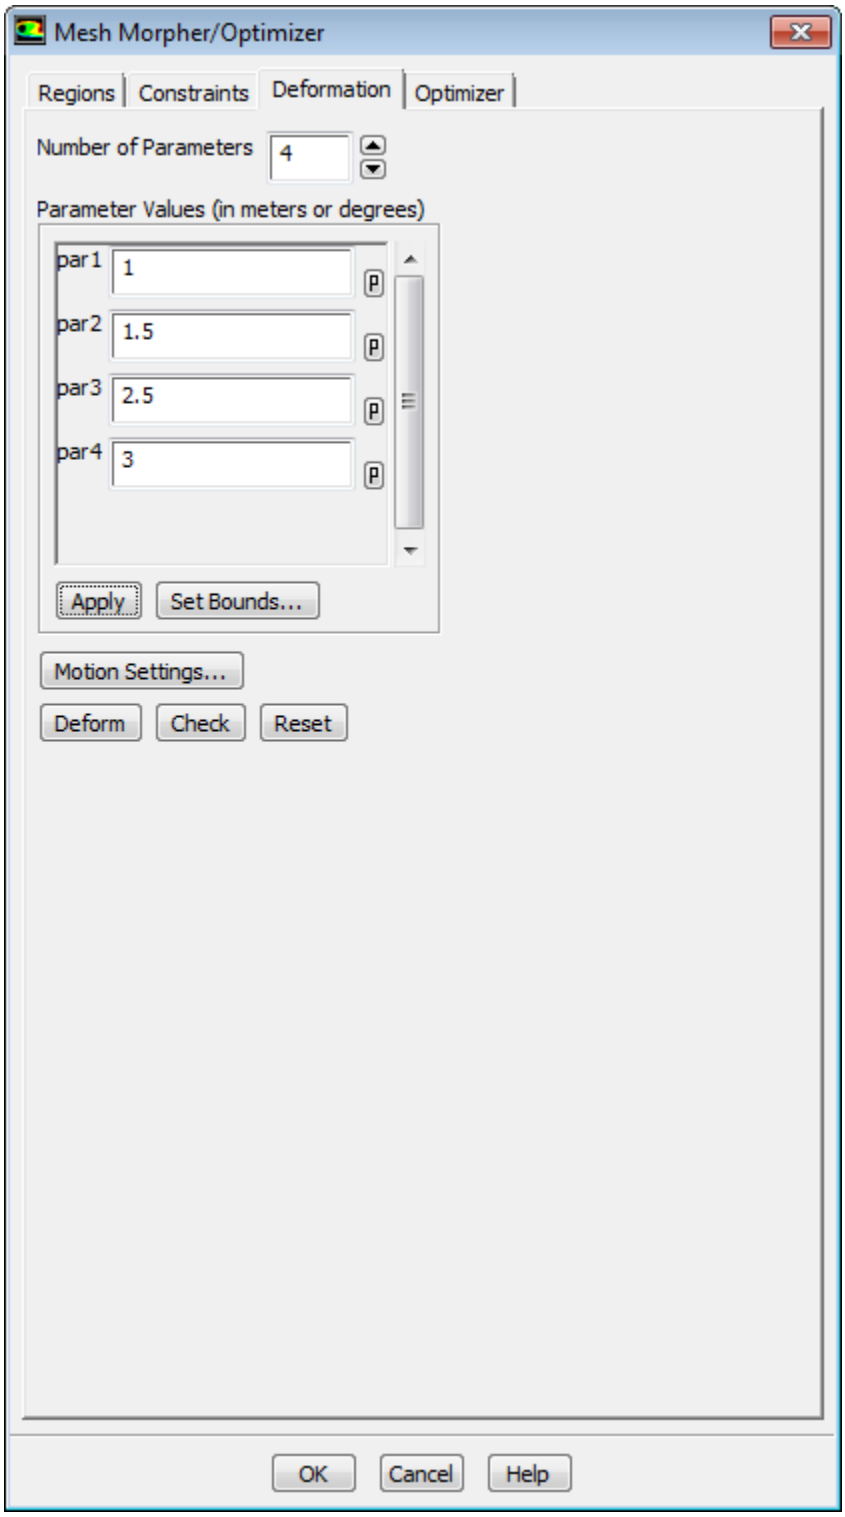
d. Click **Summary** if you would like to print a list in the console that summarizes the constraint definitions for all of the boundary zones.

7. Begin the deformation definition by defining the parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Click the **Deformation** tab (Figure 35.25: The Deformation Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2137)).

Figure 35.25: The Deformation Tab of the Mesh Morpher/Optimizer Dialog Box



b. Enter the **Number of Parameters** that will be used to define the deformation. This number may be as low as the maximum number of parameters you will define on a single control point, or as high as the total number of parameters you will set on all of the control points combined.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. If you want to manually specify the deformation or use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios (rather than using the built-in optimizers), define the parameter fields in the **Parameter Values** group box. Note that these fields are only available when **none** or **workbench** is selected from the **Optimizer** drop-down list in the **Optimizer** tab. The value of the parameter defines a magnitude that will then be used along with other direction settings to define motions that produce an overall displacement for a given control point. The value will specify a length in meters for translations and radial motions, and will specify an angle in degrees for rotations; the units here will be used regardless of what units you are using in the case.

   You have the following options:

   - If you plan to manually specify the deformation, enter a numeric value for each field in the **Parameter Values** group box. Note that having a parameter with a value of zero allows you to make a control point stationary.

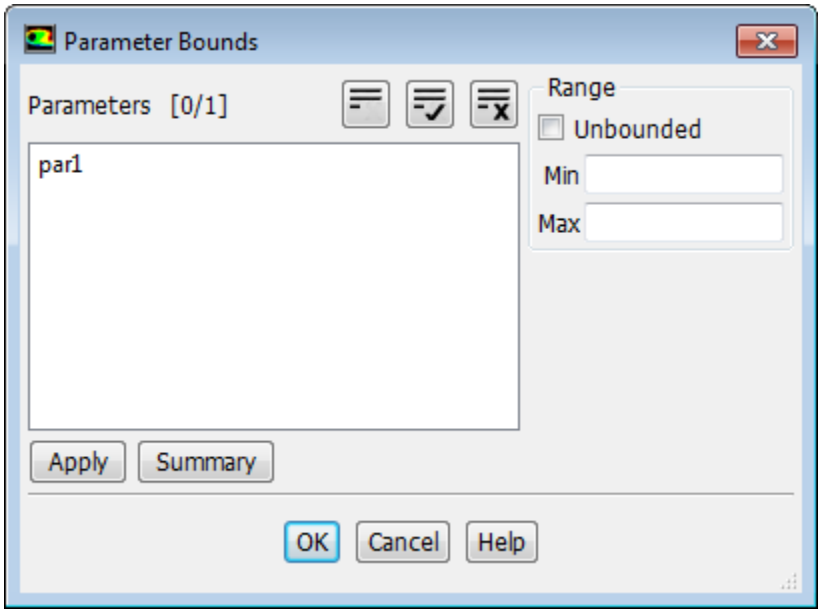
   - If you plan to use Design Exploration in ANSYS Workbench, click the P icon next to each parameter field and use the **Select Input Parameter** dialog box that opens to create or assign an input parameter with an initial value; see Select Input Parameter Dialog Box (p. 2384) for details.

   When you have finished defining the parameter fields, click the **Apply** button in the **Parameter Values** group box to save the definitions.

d. You have the option of limiting how much each parameter is allowed to deform by defining strict minimum and maximum values. This can be useful when you need to keep the parameters within a certain tolerance of the initial design, or when you know in advance that certain designs are impractical. While this option is typically used with the built-in optimizers, it is available for manual deformation, so that you can visualize the effects of the bounds and set them interactively. Note that this option is not available when **workbench** is selected from the **Optimizer** drop-down list in the **Optimizer** tab.

   Click the **Set Bounds...** button in the **Parameter Values** group box to open the **Parameter Bounds** dialog box (Figure 35.26: The Parameter Bounds Dialog Box (p. 2138)).

Figure 35.26: The Parameter Bounds Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

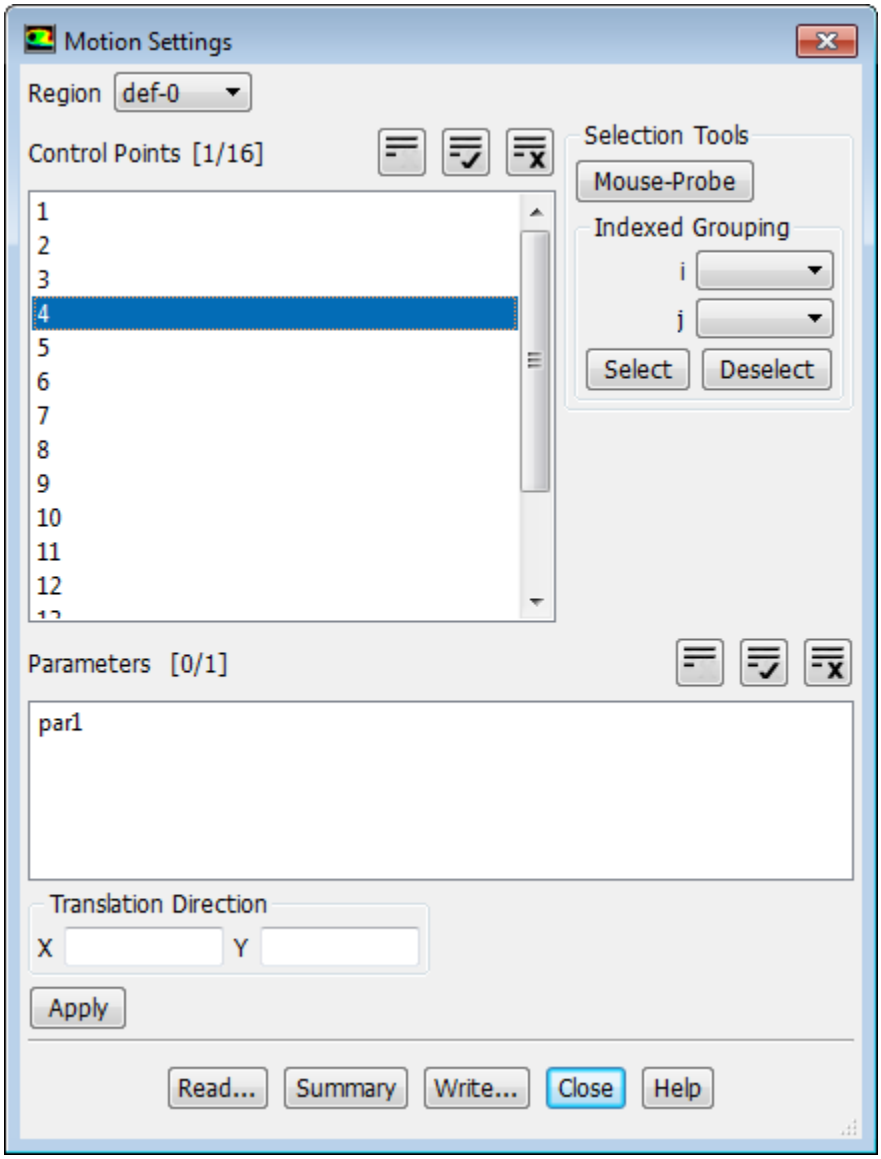
Select the parameters you want to limit from the **Parameters** selection list, disable the **Unbounded** option in the **Range** group box, and then enter appropriate values for **Min** and **Max**.

At any point you can click the **Apply** button to save your bounds, and you can click the **Summary** button to display a summary of the saved bounds in the console. When all of the parameter bounds are defined to your satisfaction, click the **OK** button to close the **Parameter Bounds** dialog box.

8. If you selected **Regular** for the **Control Point Distribution** in the **Regions** tab, perform the following steps. You will define motion settings for the control points by selecting parameters (which you defined previously) and specifying the translation direction, thus completing the deformation definition.

   a. Click the **Motion Settings...** button in the **Deformation** tab to open the **Motion Settings** dialog box (Figure 35.27: The Motion Settings Dialog Box for a Regular Distribution (p. 2139)).

Figure 35.27: The Motion Settings Dialog Box for a Regular Distribution



b. (optional) If you have previously generated an ASCII text file that contains motion settings, you can read it by clicking **Read...** at the bottom of the **Motion Settings** dialog box and using the dialog box that opens; otherwise, you should proceed to steps 8.c.–8.j. and define the settings using the other controls in the **Motion Settings** dialog box.

Using a text file can be helpful when you have a large number of motion settings. It is not necessary to create the text file from scratch, as you can create a simplified text file with sample values using the **Write...** button (as described in step 8.k.), and then add the bulk of the motion settings using a spreadsheet program. See Mesh Morpher/Optimizer File Formats (p. 2867) for details about the format of the text file.

Important

Immediately after you read a text file, the **Motion Settings** dialog box will not display the applied settings. To begin viewing the applied settings, make a selection from the **Region**, **Control Points**, and **Parameters** lists, and the associated **Translation Direction** will be displayed.

You can then edit the motion settings as necessary (in a manner similar to steps 8.c.–8.g.) and/or proceed to step 8.m.

c. Make a selection from the **Region** drop-down list in the **Motion Settings** dialog box.

d. Specify the control points in the current **Region** to which you want to assign the same motion settings (that is, the same combination of parameters and direction). You can specify these control points using one or more of the following methods:

- Select the ID numbers from the **Control Points** selection list. The selected control points will be highlighted in the graphics window.
- Click the **Mouse-Probe** button in the **Selection Tools** group box and then click the control points in the graphics window with the mouse-probe button (which is the right mouse button, by default). To deselect, select a highlighted control point with the mouse-probe button. As you select the control points, they will also be selected in the **Control Points** selection list.
- Use the **Indexed Grouping** group box to select the control points based on their assigned indices. Each control point has **i**, **j**, and (for 3D cases) **k** index numbers, each of which denote its place in the sequence (starting at the origin of the region) of control points along the direction-1, direction-2, and direction-3 vectors, respectively (as defined in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box). You can make selections from the index drop-down lists, and then click the **Select** button. In a similar way you can deselect control points using the **Deselect** button. As you select the control points, they will also be selected in the **Control Points** selection list and highlighted in the graphics window.

  For example, consider the case of a 3D region: if you select **2** from the **k** drop-down list, the control points in the second plane perpendicular to the direction-3 vector (that is, the direction-1–direction-2 plane) will be selected. If you select **1** from both the **i** and **j** drop-down lists, the line of control points at the intersection of the first planes perpendicular to the direction-1 and direction-2 vectors will be selected. Making selections from all three drop-down lists will select a single control point.

e. Make selections from the **Parameters** selection list, in order to specify those you want to assign (along with a translation direction) to the selected **Control Points**. Note that the values associated with these

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

parameters (as displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) are irrelevant if you plan to use the built-in optimizers.

f. Define the **Translation Direction** that will be associated with the selected **Parameters** by entering values for the **X**, **Y**, and (for 3D cases) **Z** directions. Note that you do not need to define a unit vector.

   If you use a built-in optimizer, these values will provide the direction of the displacement of the control point and the optimizer will determine the overall magnitude of displacement. Alternatively, if you specify the deformation manually or using Design Exploration, the values you enter in the **Translation Direction** group box will be multiplied with the values of the **Parameters** to define the displacement applied to the control points.

g. Click the **Apply** button to save the motion settings.

h. If you want to apply another set of motion settings to the selected **Control Points**, repeat steps 8.e.–8.g. for each additional combination of parameters and direction.

i. Repeat steps 8.d.–8.h. for each additional set of control points in the current **Region** to which you want to assign motion settings.

j. Repeat steps 8.c.–8.i. for each additional region in which you want to apply deformation parameters to control points.

k. If you want to save all of the settings you specified in the **Motion Settings** dialog box as an ASCII text file, click **Write...** and specify a name in the dialog box that opens. You can edit the motion settings in this text file using a spreadsheet program, and then read it in this or a separate case file, as described in step 8.b.

l. You can display a summary of the motion settings in the console by clicking the **Summary** button.

m. Click **OK** to close the **Motion Settings** dialog box.

9. If you selected **Unstructured** for the **Control Point Distribution** in the **Regions** tab, perform the following steps. You will define one or more motions—which consist of a parameter (defined previously), direction settings, and the affected control points—and thus complete the deformation definition.

Important

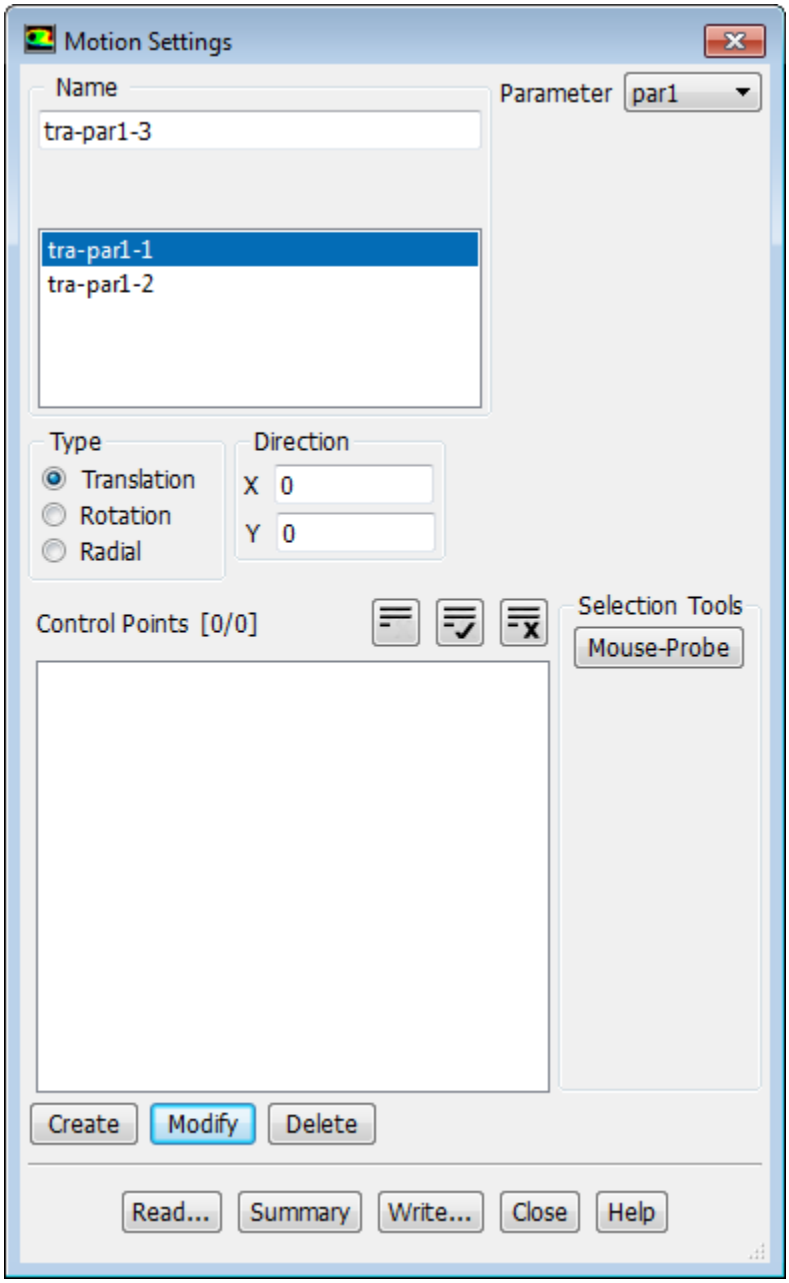
When a single control point is associated with multiple motions, note that the resultant displacement for each individual motion will be calculated from the original position, and then the displacements will be summed. This means that the order in which the motions are created will have no effect on the final location of the control point.

---

   a. Click the **Motion Settings...** button in the **Deformation** tab to open the **Motion Settings** dialog box (Figure 35.28: The Motion Settings Dialog Box for an Unstructured Distribution (p. 2142)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.28: The Motion Settings Dialog Box for an Unstructured Distribution



b. (optional) If you have previously generated an ASCII text file that contains motion definitions, you can read it by clicking **Read...** at the bottom of the **Motion Settings** dialog box and using the dialog box that opens; otherwise, you should proceed to steps 9.c.–9.k. and define the settings using the other controls in the **Motion Settings** dialog box.

   Using a text file can be helpful when you have a large number of motions. It is not necessary to create the text file from scratch, as you can create a simplified text file with sample values using the **Write...** button (as described in step 9.l.), and then add the bulk of the motion definitions using a spreadsheet program. See Mesh Morpher/Optimizer File Formats (p. 2867) for details about the format of the text file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can then either add additional motions (in a manner similar to steps 9c.–9.h.) or modify / delete an existing motion (as described in steps 9.i. and 9.j.). When the settings are finalized, you can proceed to step 9.k.

c. To begin defining a new motion, make a selection from the **Parameter** drop-down list.

d. Make a selection from the **Type** list, to indicate the type of motion you would like to define. You can specify that a group of control points undergoes a **Translation**, a **Rotation** about a point (for 2D) or an axis (for 3D), or a **Radial** motion about a point (for 2D) or an axis (for 3D).

e. Define the motion by entering **X**, **Y**, and (for 3D cases) **Z** values for the following: the **Direction** used for translations; or the **Axis Origin** and (for 3D cases) **Axis Direction** used for rotations and radial motions. For **Direction** or **Axis Direction**, note that you do not need to define unit vectors.

   If you use a built-in optimizer, the values you enter will define the direction of the displacement of the control point and the optimizer will determine the overall magnitude of displacement. Alternatively, if you specify the deformation manually or using Design Exploration, the magnitude will be the value of the **Parameter**; translation is a special case, in which the values you enter in the **Direction** group box are multiplied with the value of the **Parameter** to define the displacement applied to the control points.

f. Select the control points to which you want to assign the selected motion. You can either select them in the **Control Points** list, or click the **Mouse-Probe** button and click the control points in the graphics window using the mouse-probe button (which is the right mouse button, by default).

g. A default name will be generated in the top field of the **Name** group box, based on the **Type** and **Parameter** of the motion. You can edit this text to make it more descriptive, as necessary.

h. Click **Create** to create the motion. The name will be added to the selection list in the **Name** group box.

i. Repeat steps 9.c.–9.g. for each additional motion that you would like to create.

j. If you need to modify a motion at any point, select it in the lower selection list in the **Name** group box, revise the appropriate settings, and click the **Modify** button.

Important

When modifying an existing motion, be sure to click **Modify** rather than **Create**. If you click **Create**, you will not modify the motion, but will instead create a new one with the modified settings.

---

k. If you need to delete a deformation region at any point, select it in the lower selection list in the **Name** group box and click the **Delete** button.

l. You can display a summary of the motion definitions in the console by clicking the **Summary** button.

m. If you want to save all of the settings you specified in the **Motion Settings** dialog box as an ASCII text file, click **Write...** and specify a name in the dialog box that opens. You can edit the motion settings in this text file using a spreadsheet program, and then read it in this or a separate case file, as described in step 9.b.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. If you want to manually specify the deformation (that is, **none** is selected from the **Optimizer** drop-down list in the **Optimizer** tab of the **Mesh Morpher/Optimizer** dialog box), perform the following steps:

    a. Click the **Deform** button to apply the current settings (in the **Parameter Values** group box and **Motion Settings** dialog box) and to display the deformed mesh in the graphics window. The **Deform** button allows you to manually specify the deformation.

    b. You can click the **Check** button to print out a mesh check report in the console for the currently displayed mesh. The mesh check report is the same as that produced by the **Check** button in the **General** task page, as described in Mesh Check Report (p. 193).

    Important

    If you save parameter settings but do not click the **Deform** button, the mesh check report will not account for the mesh that is produced from those settings.

    c. Click the **Reset** button if you want to revert to the original mesh without the deformations that result from the **Deform** button.

11. If you plan to use the built-in optimizers, you should decide whether you want to disable the general mesh check that is performed by default immediately after the mesh is deformed in every design stage. The mesh check that is performed is the same as that initiated by the **Check** button in the **General** task page (see Checking the Mesh (p. 192) for details). If any errors are discovered, the mesh is rejected and the next design stage is attempted.

    Disabling the general mesh check allows you to repair the mesh, so that an accurate solution can be calculated for it. Note that you can set up the mesh repair by entering the appropriate text commands (as described in Repairing Meshes (p. 194)) in the **Initial Commands** text-entry box in the **Optimizer** tab.

    You can disable the general mesh check by using the following text command:

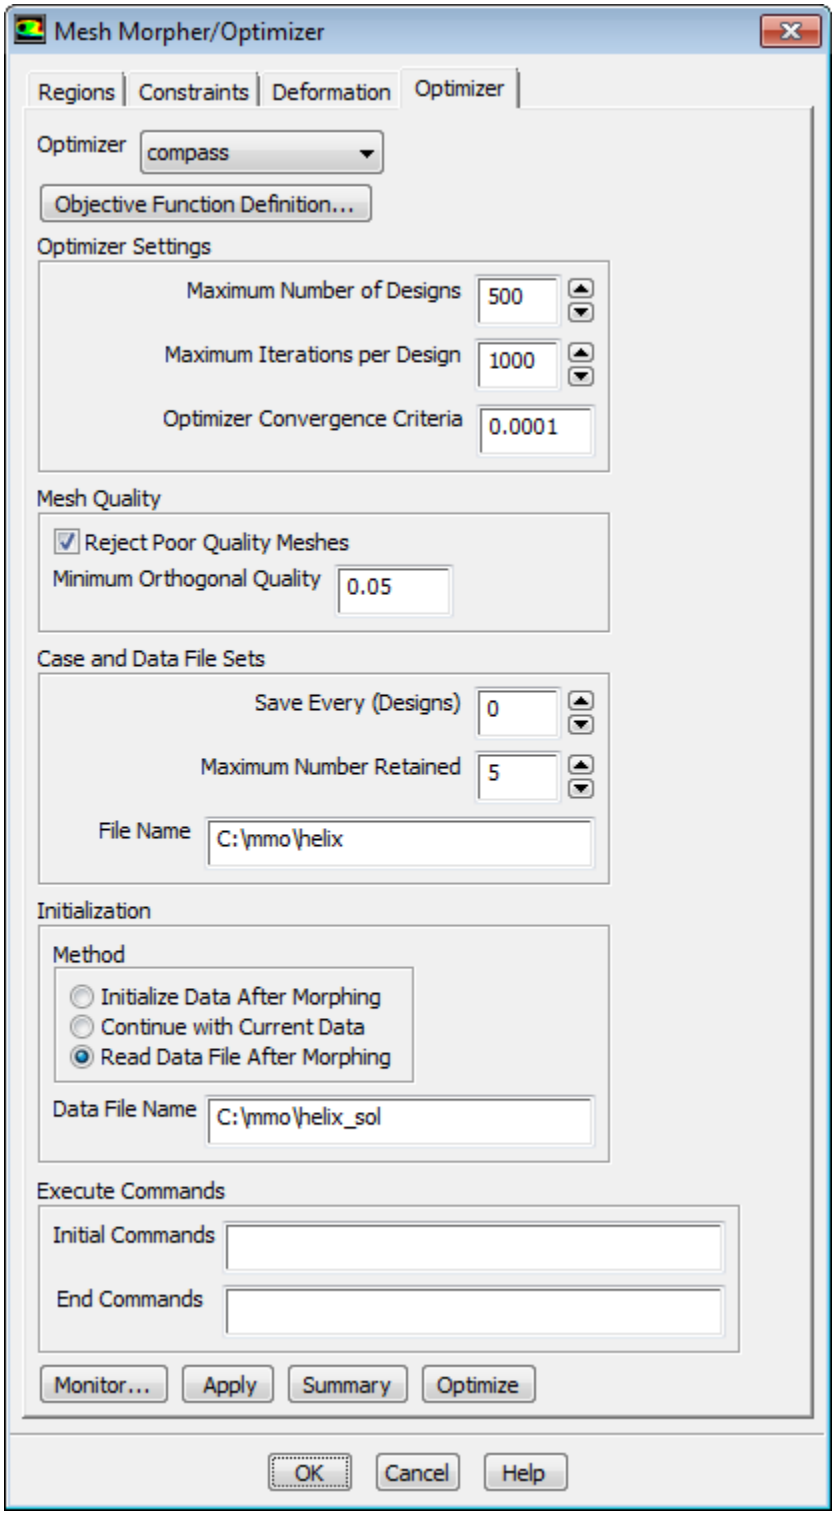
    `define → mesh-morpher-optimizer → optimizer-parameters → disable-mesh-check`

12. If you want to use the built-in optimizers, define the optimizer settings and initiate the optimization process.

    a. Click the **Optimizer** tab (Figure 35.29: The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2145)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.29: The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box

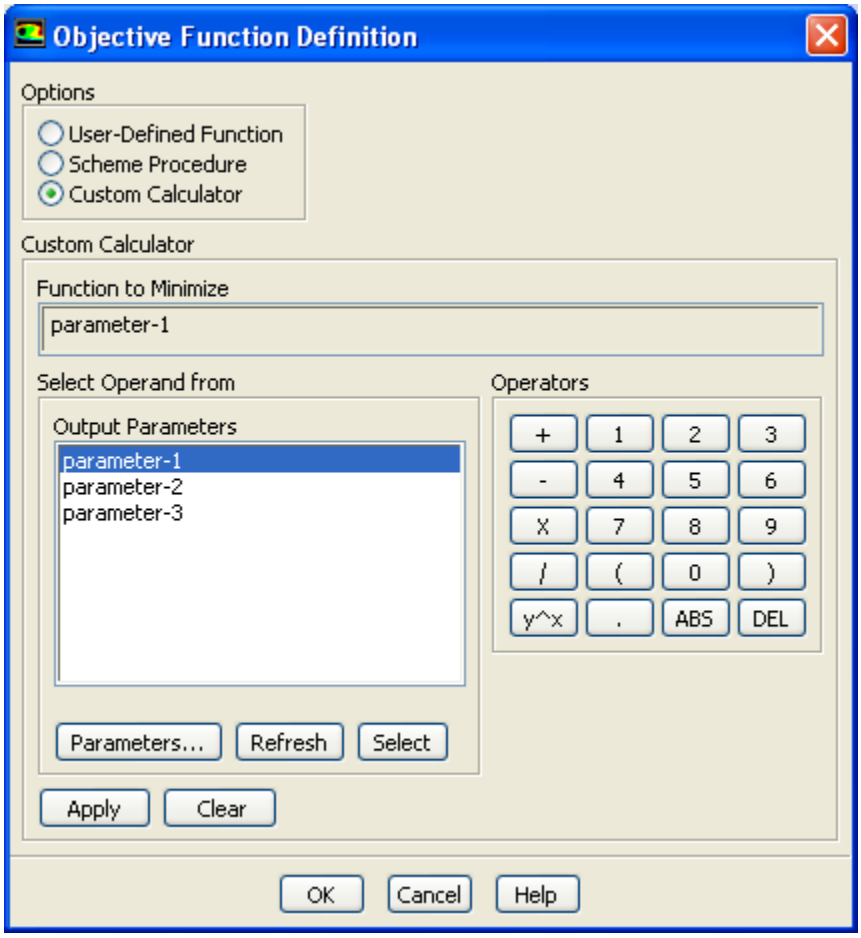


b. Select an optimizer from the **Optimizer** drop-down list. The available optimizers are not based on gradients, and include the following: **compass**, **newuoa**, **powell**, **rosenbrock**, **simplex**, and **torczon**. For more information about how these optimizers function, see Optimizers (p. 2123).

c. Click the **Objective Function Definition...** button to open the **Objective Function Definition** dialog box (Figure 35.30: The Objective Function Definition Dialog Box (p. 2146)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 35.30: The Objective Function Definition Dialog Box



i. Make a selection in the **Options** group box to specify whether the objective function that will be minimized during the optimization process is a **User-Defined Function**, a **Scheme Procedure**, or a customized function of output parameters as defined by the **Custom Calculator**. Your selection should correspond with the actions you took in step 2.

ii. If you selected **Custom Calculator** in the previous step, define the objective function via the GUI controls in the **Custom Calculator** group box. As you click the buttons in this group box, text and symbols will appear in the **Function to Minimize** text box. You *cannot* edit the contents of this box directly; if you want to delete part or all of the function, use the **DEL** or **Clear** button, respectively.

You can include output parameters in the definition of the function by making a selection from the **Output Parameters** list and clicking **Select**. If you want to add a new output parameter to the selection list or check the definition of an existing one, you can click the **Parameters...** button and use the **Parameters** dialog box (as described in Creating Output Parameters (p. 1909)); be sure to click the **Refresh** button when you return to the **Objective Function Definition** dialog box, so that the **Output Parameters** list is updated. You can also use **Operators** to manipulate the output parameters in the function.

You can click the **Apply** button at any point to save your function. When it is fully defined, click the **OK** button to save your settings and close the **Objective Function Definition** dialog box.

d. Define the settings in the **Optimizer Settings** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

i. Enter a value for **Maximum Number of Designs**, to specify the maximum number of design stages the optimizer will undergo to reach the specified objective function. Note that this number is not the number displayed in the console during the optimization process. Each optimizer undergoes a certain number of design modifications (called "runs") before it converges to a design for a particular design stage. The Run number displayed in the console refers to the actual design modifications (including the inner loop) irrespective of the optimizer, whereas the **Maximum Number of Designs** value is the maximum number of converged designs provided by the optimizer.

ii. Enter the **Maximum Iterations per Design**, to specify the maximum number of iterations ANSYS Fluent performs for each design change.

iii. Enter a number for **Optimizer Convergence Criteria**, to specify the convergence criteria for the optimizer.

iv. If you selected the **newuoa** optimizer, enter a number for the **Initial Parameter Variation** to specify how much the parameters will be allowed to vary during the initial calculations. This value is not intended to define a strict minimum / maximum for the parameters (as is defined by the bounds specified using the **Parameter Bounds** dialog box), but should only be large enough to allow the optimizer to capture the minima. A better estimation (that is, a smaller value) allows the optimizer to reach convergence faster.

e. By default, the orthogonal quality (as defined in Mesh Quality (p. 131)) of the initial and every subsequent mesh is computed, before the related solution calculation is initiated. If the orthogonal quality for any cell is less than a specified value, the mesh is rejected and Fluent proceeds to the next design stage (therefore helping to ensure that your solution accuracy is not compromised by poor quality meshes). These actions are governed by the settings in the **Mesh Quality** group box.

If you do not want the meshes rejected based on their orthogonal quality, you can disable the **Reject Poor Quality Meshes** option; otherwise, specify the minimum orthogonal quality that must be maintained by every cell by entering a value from `0`–`1` (where `0` represents the worst quality) for **Minimum Orthogonal Quality**. When determining an appropriate minimum value, you can check the orthogonal quality of the initial mesh (by using the **Report Quality** button in the **General** task page) and then select a value that is sufficiently lower, so as not to reject a majority of the meshes generated during the optimization process.

f. You have the option of saving intermediate case and data files during the optimization run, so that you can restart an interrupted solution in the same or a different Fluent session without increasing the overall number of design iterations needed to reach convergence. To enable the saving of such intermediate files, define the settings in the **Case and Data File Set** group box.

i. Specify the frequency (in number of design iterations) that you want the intermediate case and data files saved by entering a value for **Save Every**. The default value is **0**, which specifies that no intermediate files will be saved. Note that if you selected the **newuoa** optimizer, the frequency at which files are saved may not exactly correspond to the number you enter, but should be reasonably close.

ii. Specify the maximum number of intermediate files sets you want to retain by entering a value for **Maximum Number Retained**. After the maximum limit of file sets has been saved, ANSYS Fluent begins overwriting the earliest existing intermediate file set. Lower values should be used if you have limited disk space or you are concerned about saving unnecessary files.

iii. Specify a root name for the intermediate files in the **File Name** text box. When the files are saved, the design iteration will be appended to this root name to indicate the point at which it was saved during the optimization run. An extension will also be automatically added to the root name (`.cas`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or `.dat`). You can include a folder path in the filename if you want the files saved outside of the working folder.

g. Specify how the solution variables should be treated after the mesh is deformed by making a selection from the **Method** list in the **Initialization** group box:

- Select **Initialize Data After Morphing** to specify that the solution variables should be initialized to the values specified in the **Solution Initialization** task page after deformation.
- Select **Continue with Current Data** to specify that the solution variables remain the values obtained in the previous design stage. This selection will reduce the number of iterations needed to reach convergence compared to the **Initialize Data After Morphing** selection. Note that if the solver diverges during an intermediate design stage, the solution variables will be initialized and the solution will be attempted again.
- Select **Read Data File After Morphing** to specify that the solution variables are set to the values obtained from the data file specified in the **Data File Name** text-entry box. This selection will reduce the number of iterations needed to reach convergence compared to **Initialize Data After Morphing** selection or (in cases where the solution diverges for an intermediate design stage) the **Continue with Current Data** selection. Note that this selection is not available when **newuoa** is selected from the **Optimizer** drop-down list.

h. If you did not select the **newuoa** optimizer, you have the option of specifying commands that will be executed during the optimization runs of the mesh morpher/optimizer, via the text-entry boxes in the **Execute Commands** group box. A command can be a text command or the name of a command macro you have defined (or will define), as described in Defining Macros (p. 1640). You can also enter a series of text commands and/or macros, as long as they are separated by a semi-colon (`;`).

During optimization runs, deformation occurs as part of every design iteration. You decide the specific point during the design iteration that the command is executed:

- If you want a command to be executed after the design has been modified, but before ANSYS Fluent has started to run the calculation for that design stage, enter the command in the **Initial Commands** text-entry box. There are no restrictions on the commands that can be entered: you can enter commands that read saved data, perform FMG initialization, execute an entirely independent on-demand UDF, or even call a Scheme routine.
- If you want a command to be executed after the solution has run and converged for a design stage, enter the command in the **End Commands** text-entry box. There are no restrictions on the commands that can be entered. Examples are commands for postprocessing solution variables, monitoring contours and vectors of different variables, taking snapshots of each design change, and so on, at every design stage.

Important

If the command to be executed involves saving a file, see Saving Files During the Calculation (p. 1642) for important general information.

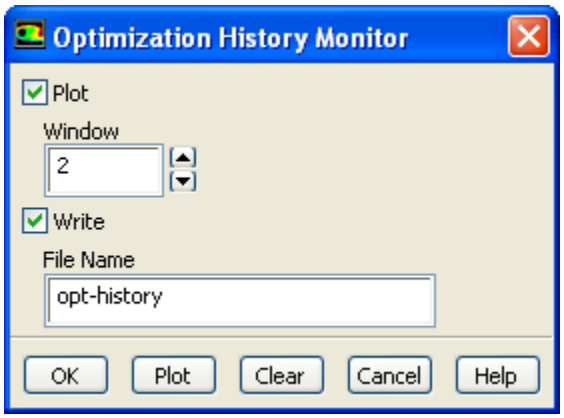
As noted in Automatic Numbering of Files (p. 43), the special character, `%i`, can be used to create unique filenames by including the iteration number. However, by default, the solution will be initialized after each mesh deformation and the iteration count restarted. Therefore, the resulting filename cannot be used to identify which design stage produced it (that is, the first design stage may con-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

verge at 50 iterations, and then the second design stage may converge at 43 iterations). The time that the file was created is a better way to identify where in the series of design stages the file was generated. In addition, some files may be overwritten if two design stages converge in the same number of iterations. Alternatively, if you have selected **Continue with Current Data** under **Initialization** when setting up the optimizer, then the iteration count will not reset and no duplicate filenames will occur.

i. If you did not select the **newuoa** optimizer, you can plot and/or record the optimization history (that is, how the value of the objective function varies with each design stage). Click the **Monitor...** button to open the **Optimization History Monitor** dialog box (Figure 35.31: The Optimization History Monitor Dialog Box (p. 2149)) and perform the steps that follow.

Figure 35.31: The Optimization History Monitor Dialog Box



i. Enable the **Plot** option if you want to display a plot of the optimization history in the graphics window indicated in the **Window** number-entry box. Note that if you want to observe the mesh deformations during the optimization process, you must make sure that **Window** is not set to the ID of the graphics window that is displaying the mesh.

ii. Enable the **Write** option if you want to save the optimization history data in a file, and specify the **File Name**.

Note that you can display a plot of the optimization history data generated during the last calculation, even if the **Plot** or the **Write** options were not enabled during the calculation, as long as you have not discarded the data using the **Clear** button. Simply click the **Plot** button and the plot will be displayed in the active graphics window.

j. Click the **Apply** button to save your optimizer settings.

k. Click the **Summary** button to display a summary of the mesh morpher/optimizer settings in the console.

l. Click the **Optimize** button to initiate the optimization process. Information about each run (that is, each design modification) that is generated as part of the production of a design stage will be displayed in the console, and the deformed mesh for each run will be updated in the graphics window.

If you set up the saving of intermediate case and data files in step 12.f and your solution is interrupted during the optimization run, you can restart the calculation using the latest intermediate files. Note that you should not revise the deformation regions or constraint settings for the restarted mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. If you want to use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, define the optimizer settings.

    a. Click the **Optimizer** tab (Figure 35.29: The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box (p. 2145)).

    b. Select **workbench** from the **Optimizer** drop-down list. Note that **workbench** is only available if you have launched your ANSYS Fluent session from ANSYS Workbench.

    c. If necessary, revise the default settings in the **Mesh Quality** group box, as described in step 12.e. Note that the design point associated with a poor quality mesh will not be updated in Workbench.

14. Click **OK** to close the **Mesh Morpher/Optimization** dialog box.

15. If you want to use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, save your case file and close your ANSYS Fluent session. You can then proceed to ANSYS Workbench and define the design points that will provide the multiple values for the input parameters you created / assigned in step 7.c. For more information about using design points to explore ANSYS Fluent results, see Working With Input and Output Parameters in Workbench in the ANSYS Fluent in Workbench User's Guide.

16. If you manually deformed the mesh or used the built-in optimizers, run your case file with the deformed mesh.

17. If you want to rerun a case file in which the mesh has been deformed by the **Optimize** button in the **Optimizer** tab, you should not revise the deformation regions or constraint settings for the deformed mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 36: Customizing Fluent

36.1. Customizing Fluent with ANSYS ACT

ANSYS ACT functionality is available for stand-alone Fluent as well as Fluent in Workbench. There are three ways that you can enable ACT functionality:

- Enable the **Load ACT** option in the Fluent Launcher.
- Select **ACT** from the **Arrange the workspace** ( ) drop-down.
- Enter the text command: `file/load-act-tool`.

The **ACT Start Page** *will open as a new component in the Fluent layout*.

36.1.1. ACT Start Page: Accessing ACT Functionality

The **ACT Start Page** provides an access point for ACT functionality. From this page, you can access tools that can be used in the development and execution of extensions.

For additional information, see Using the ACT Start Page in the *ANSYS ACT Developer's Guide*.

36.1.2. Extension Manager: Working with Extensions

Click the **Extension Manager** icon on the **ACT Start Page**.

The **Extension Manager** tool shows all of the extensions that are currently installed (scripted extensions are listed only if you have an ACT license). Extensions with green backgrounds are the ones that have already been loaded. The following general functionality is available:

- Click a "+" icon to install a new binary extension.
- Click the gear icon to add a directory that ACT will search for extensions. (This is how you will install scripted extensions since the install extension capability applies only to binary extensions.)

> **Note**
>
> The directory containing the IronPython script must have the same name as the `.xml` extension file.

- Click the **ANSYS App Store** button to access extensions available for download.
- Use the search field to find a specific extension.

You can also right-click an extension to open a context menu showing the available options for that extension, including:

- Loading/unloading extensions
- Specifying whether an extension is loaded by default
- Uninstalling binary extensions
- Building scripted extensions

For more detailed information, see Extension Manager Accessed via the ACT Start Page in the *ANSYS ACT Developer's Guide*.

36.1.3. Wizards Page: Working with Wizards

ACT wizards enable you to use ACT's process-compression and automation capabilities in Fluent, regardless of whether Fluent is opened in Workbench or as a stand-alone application. Once launched, a wizard provides guidance within the application workflow, walking users step-by-step through a fluid dynamics simulation.

An ACT wizard is encapsulated in an extension, placed within a `<wizard>` block in the extension XML definition file; one or more wizards can be defined within the same extension. In order to use a wizard, you must install and load the extension via the Extension Manager, as described in Extension Manager: Working with Extensions (p. 2151).

To access the **Wizards** page, click the corresponding icon on the **ACT Start Page**. The **Wizards** tool shows all of wizards currently installed for Fluent. You can use the **Search** field to search for a wizard by the name, description, or author of the extension.

To execute a wizard, click it. Alternatively, you can select **Execute Wizard** from the wizard's context menu. The wizard interface will open, showing the first step of the wizard.

For more information on wizards in general, see Using Wizards in the *ANSYS ACT Developer's Guide*.

36.1.3.1. Fluent Wizard Example: Simple Analysis

This example uses a Fluent wizard called **SimpleAnalysis**. It is defined in the extension **FluentDemo** (XML Extension Definition File (p. 2152)). You can find this extension in the **ACT Templates** section of the ANSYS Customer Portal.

This example imports a mesh, runs a simple analysis, generates results, and displays the results in a customized panel in the UI. At minimum, an extension consists of an XML Extension Definition File (p. 2152) and an IronPython Script (p. 2155).

Note

This example requires you to run Fluent in 3D (selected from the Fluent Launcher). It also requires you to download the mesh file `final.msh` from the ANSYS App Store. When you click **ACT Wizard Templates** under **ACT Templates**, you will be prompted to download the folder.

36.1.3.1.1. XML Extension Definition File

This section contains the `FluentDemo.xml` extension file, as well as explanations of each of the required fields.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Extension Definition

The `name` and `version` attributes define the extension name and version. The `guid` specifies a unique identifier for the extension.

Script Reference

The `<script>` block specifies the IronPython script referenced by the extension. This wizard references the script `main.py` (IronPython Script (p. 2155)).

Interface Definition

The `<interface>` block defines details of the interface.

- The `context` attribute is set to `Fluent` because the extension is executed in the Fluent application.
- The `<images>` block refers the extension **images** folder; the image contained in this folder is displayed as the icon for the wizard.

User Interface Definition

The `<uidefinition>` block allows you to customize the ACT user interface, by creating specialized views and layouts.

- The `<layout>` block allows you to define a custom layout. In this example, only a single layout is defined.
  - The `name` attribute is set to `ResultsView`, specifying the name of the layout being defined (a customized view for the display of Fluent results).
  - The following child `<component>` blocks define the details and display properties of each UI component included in the custom layout: `Title`, `Properties`, `Report`, `Chart`, and `Submit`.

Wizard Definition

The wizard and its steps are defined in the `<wizard>` block.

- The required `name` and `version` attributes define the wizard name and version.
- The `context` attribute is set to `Fluent` because the wizard will be executed in the Fluent application.
- The `icon` attribute references the `wizard_icon.png` image in the **images** folder.

Step Definitions

The `<step>` tab is used to define the steps of the wizard. There are two steps:

`Analysis` and `Results`.

For each step:

- The `name`, `version`, and `caption` attributes define the step name, version, and display text for the step.
- The `<callbacks>` block defines the callbacks to the functions defined in the `main.py` Python script.
  - For the Analysis step:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

→ The <onrefresh> callback executes the ImportMesh function.

→ The <onupdate> callback executes the CreateAnalysis function.

– For the Results step, the <onrefresh> callback executes the CreateReport function.

- The <property> block for each step defines a single property and its attributes.

XML Example:

```
<extension name="FluentDemo" version="1">
 <guid>A0A3E28C-E094-4B2D-8A91-A0B0884D1AE2</guid>
 <author>ANSYS Inc.</author>
 <description>This extension demonstrates how to create a wizard in Fluent.</description>

36.1.3.1.2. IronPython Script

This section contains the IronPython script, `main.py`. It is located in the **FluentDemo** extension folder.

This script defines all of the functions executed by the callbacks in the XML extension file: `ImportMesh`, `CreateAnalysis`, and `CreateReport`. Each step defined in the XML file may include multiple actions.

Note

The `ImportMesh` function references the input file `final.msh`. It is located in the **Fluent-Demo** extension folder, along with the `main.py` script.

```
def CreateMesh(step):
    tui = ExtAPI.Application.ScriptByName("TUI")

    tui.SendCommand("""switch-to-meshing-mode""")
    tui.SendCommand("""/file/import/cad yes "{0}" 40 yes m""".format(r"e:\models\cyl.agdb"))

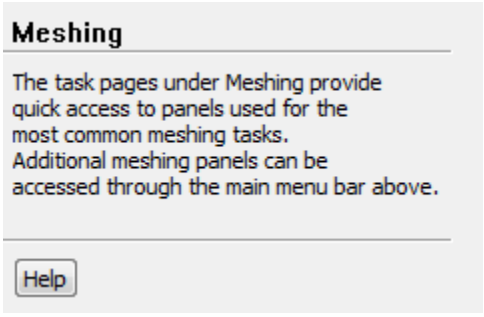
Chapter 37: Task Page Reference Guide

This reference guide provides information about the task pages in Fluent.

37.1. Meshing Task Page
37.2. Solution Setup Task Page
37.3. General Task Page
37.4. Models Task Page
37.5. Materials Task Page
37.6. Phases
37.7. Cell Zone Conditions Task Page
37.8. Boundary Conditions Task Page
37.9. Overset Interfaces Task Page
37.10. Dynamic Mesh Task Page
37.11. Reference Values Task Page
37.12. Solution Task Page
37.13. Solution Methods Task Page
37.14. Solution Controls Task Page
37.15. Solution Initialization Task Page
37.16. Calculation Activities Task Page
37.17. Run Calculation Task Page
37.18. Results Task Page
37.19. Graphics and Animations Task Page
37.20. Plots Task Page
37.21. Reports Task Page
37.22. Parameters and Customization Task Page

37.1. Meshing Task Page

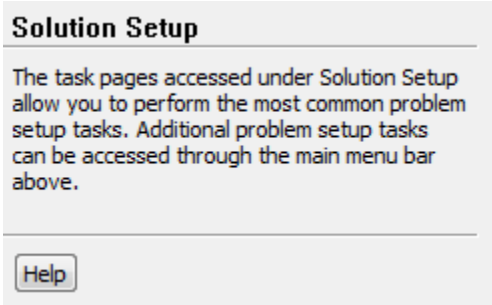
The **Meshing** task page introduces you to the most common meshing tasks involved in solving your CFD simulation using ANSYS Fluent.



37.2. Solution Setup Task Page

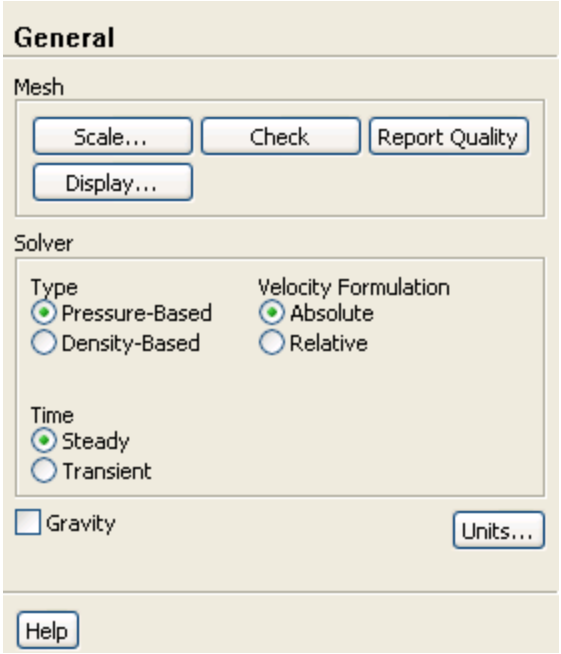
The **Solution Setup** task page introduces you to the main tasks involved in setting up your CFD simulation using ANSYS Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



37.3. General Task Page

The **General** task page allows you to set various generic problem settings, such as those related to the mesh or the solver.



Controls

Mesh

contains controls relating to mesh settings.

Scale...

opens the Scale Mesh Dialog Box (p. 2162).

Check

verifies the validity of the mesh. The check provides volume statistics, mesh topology and periodic boundary information, verification of simplex counters, and verification of node position with reference to the x axis for axisymmetric cases. See Checking the Mesh (p. 192) for details.

It is recommended that you check the mesh right after reading it into the solver, in order to detect any mesh trouble before you get started with the problem setup.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Quality
displays various quantities related to the quality of the mesh in the console, such as `Minimum Orthogonal Quality` and `Maximum Aspect Ratio`. See Mesh Quality (p. 131) for details.

Display...
opens the Mesh Display Dialog Box (p. 2163).

Solver
contains controls relating to solver settings.

Type
contains the solution methods available for computing a solution for your model. See Using the Solver (p. 1551) for details.

Pressure-Based
enables the pressure-based Navier-Stokes solution algorithm (the default).

Density-Based
enables the density-based Navier-Stokes coupled solution algorithm.

Velocity Formulation
specifies the velocity formulation to be used in the calculation. See Choosing the Relative or Absolute Velocity Formulation (p. 609) for details.

Absolute
enables the use of the absolute velocity formulation. This is the default setting.

Relative
enables the use of the relative velocity formulation. This option is available only with the **Pressure-Based** solver.

Time
contains options related to time dependence.

Steady
specifies that a steady flow is being solved.

Transient
enables a time-dependent solution. See Performing Time-Dependent Calculations (p. 1608) for details.

2D Space
contains options available only when solving two-dimensional problems.

Planar
indicates that the problem is two-dimensional. (This option is available only when you start the 2D version of the solver.)

Axisymmetric
indicates that the domain is axisymmetric about the x axis. When **Axisymmetric** is enabled, the 2D axisymmetric form of the governing equations is solved instead of the 2D Cartesian form. (This option is available only when you start the 2D version of the solver.) Be sure to change the zone type of the axis of rotation to **axis**, using the Boundary Conditions Task Page (p. 2389), as described in Changing Cell and Boundary Zone Types (p. 239).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axisymmetric Swirl
specifies that the swirl component (circumferential component) of velocity is to be included in your axisymmetric model. You should select this option if you are solving swirling flow in an axisymmetric geometry (see Swirling and Rotating Flows (p. 587) for more information).

Gravity
enables the specification of gravity.

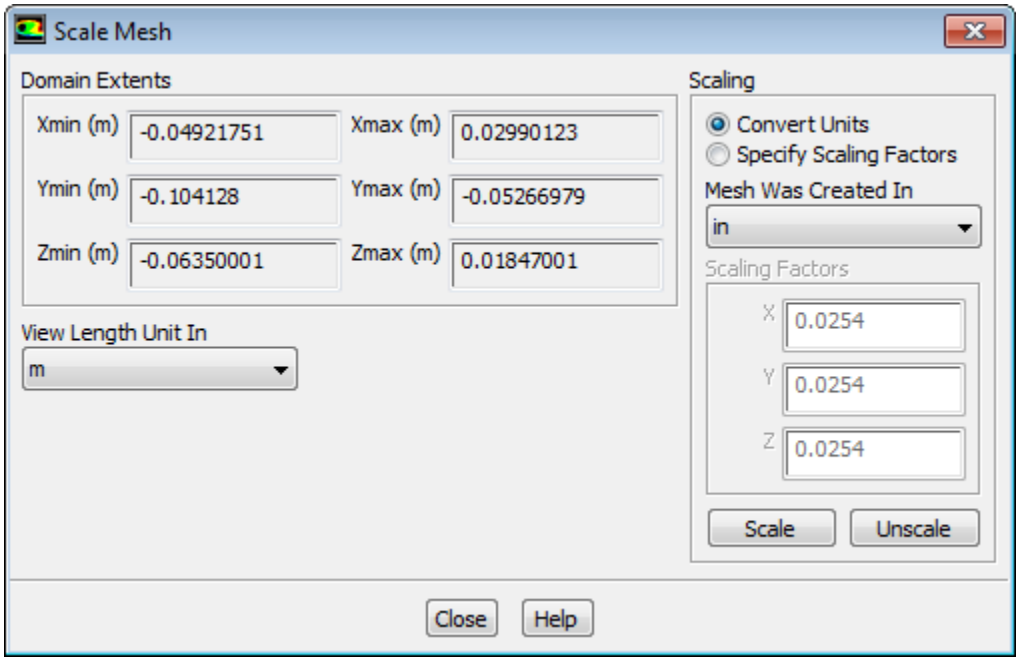
Gravitational Acceleration
sets the x, y, and z components of the gravitational acceleration vector. (The z component is available only in 3D solvers.) See Natural Convection and Buoyancy-Driven Flows (p. 833) for details about buoyancy-driven flows. This option appears only when **Gravity** is enabled.

Units...
opens the Set Units Dialog Box (p. 2166).

For additional information, see the following sections:
37.3.1. Scale Mesh Dialog Box
37.3.2. Mesh Display Dialog Box
37.3.3. Set Units Dialog Box
37.3.4. Define Unit Dialog Box
37.3.5. Mesh Colors Dialog Box

37.3.1. Scale Mesh Dialog Box

The **Scale Mesh** dialog box allows you to convert the mesh from various units of measurement to SI or to apply custom scale factors to the individual coordinates of the mesh. See Scaling the Mesh (p. 226) for details.



Controls

Domain Extents
displays the Cartesian coordinate extremes of the nodes in the mesh. (These values are not editable; they are purely informational.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Xmin, Ymin, Zmin
shows the minimum values of Cartesian coordinates in the mesh.

Xmax, Ymax, Zmax
shows the maximum values of Cartesian coordinates in the mesh.

Scaling
contains controls for converting units and setting the scale factors automatically.

Convert Units
allows you to use the conversion factors provided by ANSYS Fluent. Then indicate the units used when creating the mesh by selecting the appropriate abbreviation for meters, centimeters, millimeters, inches, or feet from the **Mesh Was Created In** drop-down list. The **Scaling Factors** will automatically be set to the correct values (for example, 0.0254 meters/inch).

Specify Scaling Factors
allows you to manually specify a scale factor in each of the Cartesian coordinate directions.

Mesh Was Created In
contains a list of common units of length. The **Scaling Factors** will automatically be set based on your selection. The units include common SI and British units such as centimeters (cm), millimeters (mm), inches (in), and feet (ft).

Scaling Factors
contains the factors applied to the mesh in each of the Cartesian coordinate directions. You can enter values manually, or use the **Mesh Was Created In** list to set scale factors automatically.

X
is the scale factor in the x direction.

Y
is the scale factor in the y direction.

Z
is the scale factor in the z direction (appears only in 3D).

Scale
multiplies each of the node coordinates by the specified scale factors.

Unscale
divides each of the node coordinates by the specified scale factors.

View Length Unit In
contains a list of common units of length. The **Domain Extents** will automatically be set based on your selection. The units include common SI and British units such as centimeters (cm), millimeters (mm), inches (in), and feet (ft). The units of length in the Set Units Dialog Box (p. 2166) will change each time you change your selection in the **View Length Unit In** drop-down list.

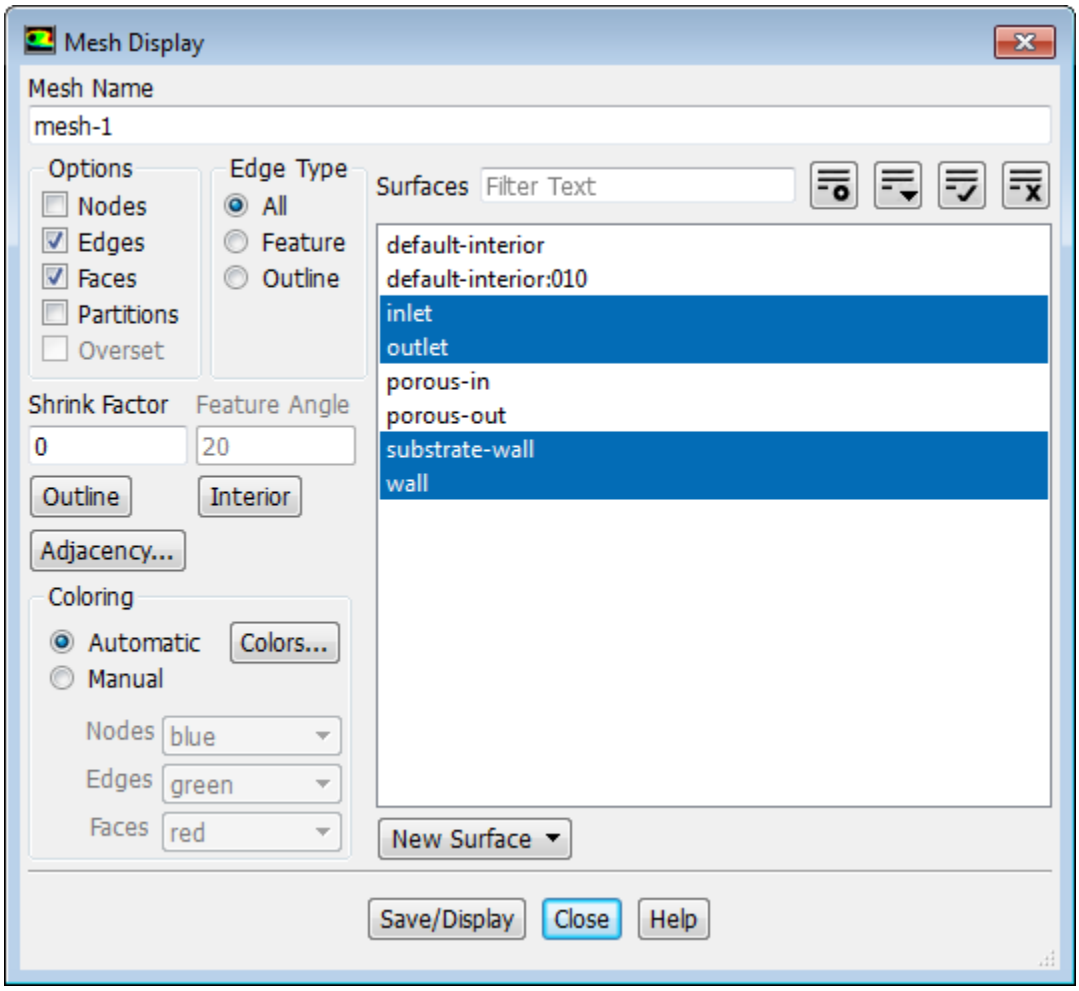
37.3.2. Mesh Display Dialog Box

The **Mesh Display** dialog box controls the display of zone, surface, and partition boundary meshes. See Displaying the Mesh (p. 1748) for details about the items below.

*You can also access the **Mesh Display** dialog box through the **Postprocessing** ribbon tab.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Postprocessing → Graphics → Mesh → New...



Controls

Mesh Name

is the name for a mesh display definition. You can specify a name or use the default name `mesh-id`. This control appears only for mesh display definitions.

Options

contains the rendering options described below. To see the effects of your selection you must click the **Display** button.

Nodes

enables the display of nodes on the selected surfaces.

Edges

enables the display of mesh edges on the selected surfaces.

Faces

enables the display of mesh faces (filled meshes) on the selected surfaces.

Partitions

enables the display of partition boundaries.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Overset
when enabled, displays only the solve cells for cases with overset interfaces. Receptor cells are also displayed if the text command `define/overset-interfaces/options/render-receptor-cells?` is set to `yes`.

Shrink Factor
specifies the amount to shrink faces and cells. See Shrinking Faces and Cells in the Display (p. 1754) for details.

Edge Type
controls the display of edges. (These items will not appear if the **Edges** option is turned off.)

All
enables the display of all mesh edges.

Feature
enables feature lines in an outline display. See Adding Features to an Outline Display (p. 1753) for details.

Outline
enables the display of the mesh outline.

Feature Angle
controls the amount of detail added to a feature outline display. See Adding Features to an Outline Display (p. 1753) for details. (This item will be available only if the **Feature** edge type is enabled.)

Surfaces
contains a list from which you can select the surfaces for which the mesh is to be drawn.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

Outline
selects all "outline" boundaries in the **Surfaces** list. If all outline boundaries are already selected, it deselects them.

Interior
selects all "interior" surfaces in the **Surfaces** list. If all interior surfaces are already selected, it deselects them.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Adjacency
opens the Adjacency Dialog Box (p. 2664) from which you can identify and display face zones that are adjacent to selected cell zones.

Coloring

Automatic
nodes, edges, and faces are automatically colored by type or ID, depending on which is specified in the Mesh Colors Dialog Box (p. 2168).

Colors...
opens the Mesh Colors Dialog Box (p. 2168).

Manual
allows you to manually specify the color of nodes, edges, and faces, if enabled under **Options**.

Nodes
specify the color for the nodes.

Edges
specify the color for the edges.

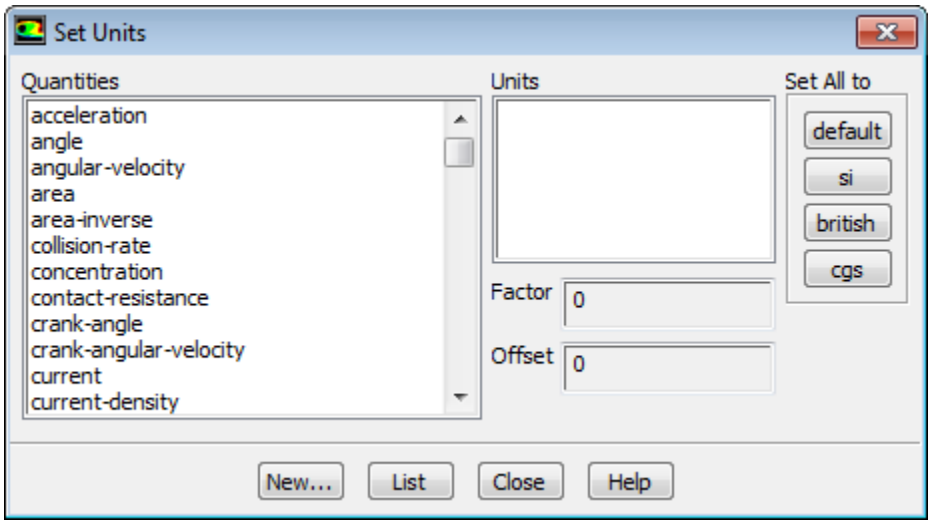
Faces
specify the color for the faces.

Display
displays the defined mesh plot.

Save/Display
displays the mesh in the active graphics window and saves the mesh display definition. This button appears only for mesh display definitions and replaces the **Display** button.

37.3.3. Set Units Dialog Box

The **Set Units** dialog box allows you to set the units system for any quantity used in ANSYS Fluent. All quantities may be set to a standard system, such as SI or British, or the units of individual quantities may be set. See Unit Systems (p. 111) for details about the items below.



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Quantities
displays the list of all quantities used by ANSYS Fluent for input and output.

Units
lists the units appropriate for the currently selected quantity. Selecting an item in the **Units** list causes that unit to be used for the currently selected quantity.

Factor
displays the conversion factor from the currently selected units to SI.

Offset
displays the conversion offset from the currently selected units to SI.

Set All to
contains standard sets of units that are applied to all quantities when selected.

default
is similar to **si**, but uses degrees instead of radians for angles.

si
selects the System International (SI) standard for all units.

british
selects the English Engineering standard for all units.

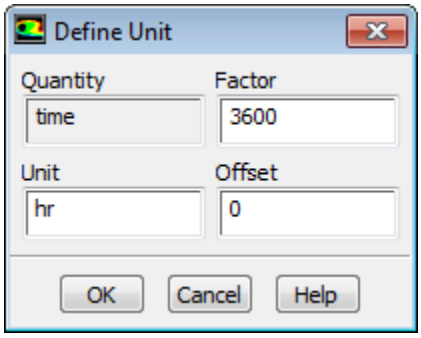
cgs
selects the CGS (centimeter-gram-second) standard for all units

New...
opens the Define Unit Dialog Box (p. 2167), in which you can specify a customized unit for a particular quantity.

List
displays the current units for all quantities in the console.

37.3.4. Define Unit Dialog Box

The **Define Unit** dialog box allows you to customize the units for a particular quantity. It is opened from the Set Units Dialog Box (p. 2166). For details about using this dialog box, see Defining a New Unit (p. 113).



Controls

Quantity
shows the name of the quantity for which you are defining a new unit. (You cannot edit this field; the quantity is selected in the Set Units Dialog Box (p. 2166).)

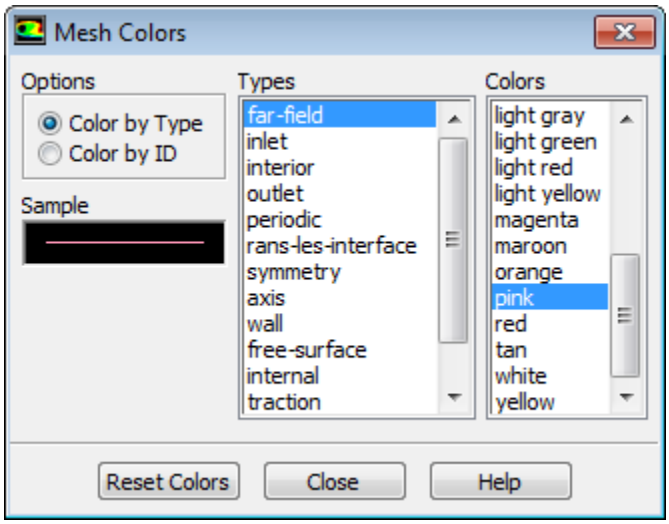
Unit
sets the name for the new unit.

Factor
sets the conversion factor from the currently selected units to SI.

Offset
sets the conversion offset from the currently selected units to SI.

37.3.5. Mesh Colors Dialog Box

The **Mesh Colors** dialog box allows you to control the colors that are used to draw meshes. It is opened from the Mesh Display Dialog Box (p. 2163). See Modifying the Mesh Colors (p. 1752) for details about the items below.



Controls

Options
contains options to select the method by which to set the colors.

Color by Type
sets the color based on the type of zone.

Color by ID
sets the color by ID.

Types
contains a selectable list of zone types. You can select the zone type for which you want to set the color.

Colors
contains a list from which you can select a color for the selected type.

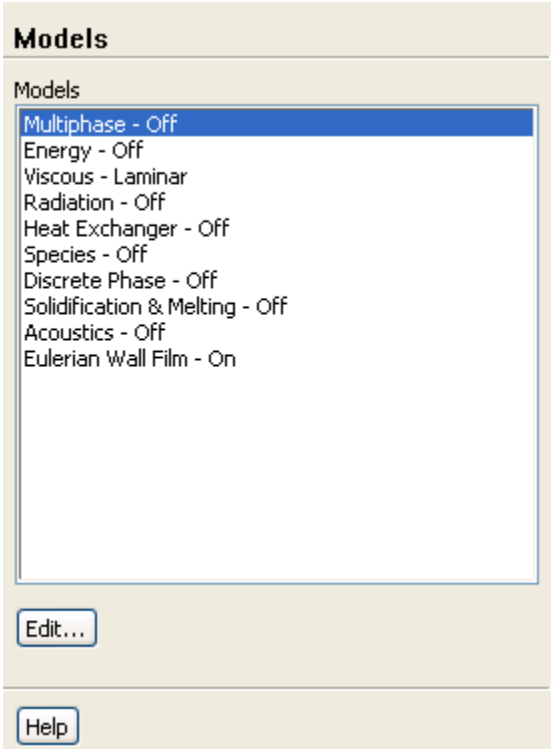
Sample
displays a sample of the currently selected color.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reset Colors
resets the mesh colors to the default selections.

37.4. Models Task Page

The **Models** task page allows you to set various generic model settings.



Controls

Models
contains a listing of the various models available in ANSYS Fluent.

You can double-click an item in the **Models** list to open the corresponding dialog box, or you can select the item in the list and click the **Edit...** button.

Multiphase
- selecting this item and clicking the **Edit...** button opens the Multiphase Model Dialog Box (p. 2171).

Energy
- selecting this item and clicking the **Edit...** button opens the Energy Dialog Box (p. 2175).

Viscous
- selecting this item and clicking the **Edit...** button opens the Viscous Model Dialog Box (p. 2176).

Radiation
- selecting this item and clicking the **Edit...** button opens the Radiation Model Dialog Box (p. 2190).

Heat Exchanger
- selecting this item and clicking the **Edit...** button opens the Heat Exchanger Model Dialog Box (p. 2200).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Species
- selecting this item and clicking the **Edit...** button opens the Species Model Dialog Box (p. 2216).

The following models are made available, depending on your setup of the **Species** dialog box.

- **Spark Ignition** - selecting this item and clicking the **Edit...** button opens the Spark Ignition Dialog Box (p. 2243). Note that spark ignition is only available for transient calculations.
- **Autoignition** - selecting this item and clicking the **Edit...** button opens the Autoignition Model Dialog Box (p. 2246). Note that autoignition is only available for transient calculations.
- **Inert** - selecting this item and clicking the **Edit...** button opens the Inert Dialog Box (p. 2249). Note that the inert model is only available when the non-premixed or partially premixed model is selected in the **Species Model** dialog box, or when a PDF file is read.
- **NOx** - selecting this item and clicking the **Edit...** button opens the NOx Model Dialog Box (p. 2250). Note that the NOx model is not compatible with premixed combustion.
- **SOx** - selecting this item and clicking the **Edit...** button opens the SOx Model Dialog Box (p. 2258). Note that the SOx model is not compatible with premixed combustion.
- **Soot** - selecting this item and clicking the **Edit...** button opens the Soot Model Dialog Box (p. 2262). Note that none of the soot models are compatible with premixed combustion.
- **Decoupled Detailed Chemistry** - selecting this item and clicking the **Edit...** button opens the Decoupled Detailed Chemistry Dialog Box (p. 2273).
- **Reacting Channel Model** - selecting this item and clicking the **Edit...** button opens the Reacting Channel Model Dialog Box (p. 2274).

Discrete Phase
- selecting this item and clicking the **Edit...** button opens the Discrete Phase Model Dialog Box (p. 2278).

Solidification & Melting
- selecting this item and clicking the **Edit...** button opens the Solidification and Melting Dialog Box (p. 2288).

Acoustics
- selecting this item and clicking the **Edit...** button opens the Acoustics Model Dialog Box (p. 2289).

Eulerian Wall Film
- selecting this item and clicking the **Edit...** button opens the Eulerian Wall Film Dialog Box (p. 2294).

Edit...
displays the dialog box corresponding to the selected item in the **Models** list.

For additional information, see the following sections:
37.4.1. Multiphase Model Dialog Box
37.4.2. Energy Dialog Box
37.4.3. Viscous Model Dialog Box

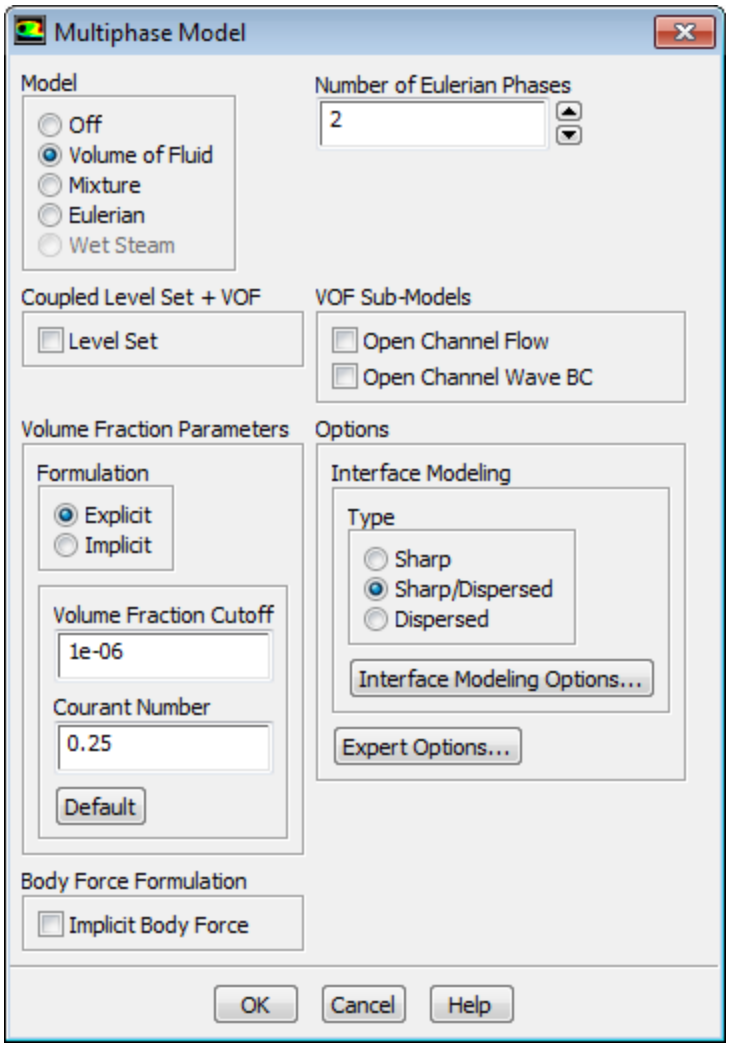
37.4.47. Acoustic Sources Dialog Box
37.4.48. Acoustic Receivers Dialog Box
37.4.49. Interior Cell Zone Selection Dialog Box
37.4.50. Eulerian Wall Film Dialog Box
37.4.51. Potential Dialog Box

37.4.1. Multiphase Model Dialog Box

The **Multiphase Model** dialog box allows you to set parameters for modeling multiphase flow. See Enabling the Multiphase Model (p. 1367) – Including Cavitation Effects (p. 1455) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

allows you to select one of four multiphase models.

Off

disables the calculation of multiphase flow.

Volume of Fluid

enables the VOF model described in Volume of Fluid (VOF) Model Theory in the Theory Guide. See Setting Up the VOF Model (p. 1408) for details about using the model. This is available only with the pressure-based solver.

Mixture

enables the mixture model described in Mixture Model Theory in the Theory Guide. See Setting Up the Mixture Model (p. 1447) for details about using the model. This is available only with the pressure-based solver.

Eulerian

enables the Eulerian model described in Eulerian Model Theory in the Theory Guide. See Setting Up the Eulerian Model (p. 1455) for details about using the model. This is available only with the pressure-based solver.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Wet Steam
enables the wet steam model described in Wet Steam Model Theory in the Theory Guide. See Setting Up the Wet Steam Model (p. 1495) for details about using the model. This is available only with the density-based solver.

Number of Eulerian Phases
allows you to specify the number of phases for the multiphase calculation. You can specify up to 20 phases.

Coupled Level Set + VOF
allows you to apply an interface tracking method that couples the level set method with the VOF formulation.

Volume Fraction Parameters
contains parameters related to the VOF and Eulerian model. This section of the dialog box will appear only when **Volume of Fluid** or **Eulerian** is the selected **Model**.

Formulation
allows you to select the desired volume tracking formulation.

Explicit
enables the Euler explicit formulation, described in The Explicit Formulation in the Theory Guide. See Choosing Volume Fraction Formulation (p. 1371) for more information.

Implicit
enables the implicit formulation, described in The Implicit Formulation in the Theory Guide. See Choosing Volume Fraction Formulation (p. 1371) for more information.

Volume Fraction Cutoff
specifies a cutoff limit for the volume fraction values. The value that you provide is used as the lower cutoff for the volume fraction. All volume fraction values in the domain below this cutoff value are set to zero. The upper cutoff is calculated as (1.0 - lower cutoff). All volume fraction values above the upper cutoff value are set to 1.0. The default value is 1e-6.

Important

The **Volume Fraction Cutoff** value can be specified when using the VOF model, or when using the Eulerian Multiphase model with the **Explicit** scheme.

Courant Number
specifies the maximum Courant number allowed near the free surface. This item will not appear if the **Implicit Scheme** is selected. See Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation (p. 1445) for details.

Mixture Parameters
contains options related to the **Mixture** model.

Slip Velocity
enables/disables the calculation of slip velocities for the secondary phases as described in Relative (Slip) Velocity and the Drift Velocity in the Theory Guide. See also Solving a Homogeneous Multiphase Flow (p. 1375).

Eulerian Parameters
contains options related to the **Eulerian** model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Dense Discrete Phase Model
allows you to include the Dense Discrete Phase model (see Including the Dense Discrete Phase Model (p. 1481) for details). Enabling this model automatically enables the DPM model.

Multi-Fluid VOF Model
allows you to include the multi-fluid VOF model (see Including the Multi-Fluid VOF Model (p. 1493) for details). The multi-fluid VOF model allows the modeling of interface sharpening schemes and free surface flow.

Boiling Model
allows you to include the Boiling model (see Including the Boiling Model (p. 1486) for details).

Boiling Model Options
allows you to select the type of boiling model to apply to your case.

RPI Boiling Model
is where the total heat flux from the wall to the liquid is partitioned into three components, namely the convective heat flux, the quenching heat flux, and the evaporative heat flux. Details about this model can be found in RPI Model in the Theory Guide.

Non-equilibrium Boiling
is a modification to the RPI model in order to model different boiling regimes like DNB and critical heat flux. Details about this model can be found in Non-equilibrium Subcooled Boiling in the Theory Guide.

Critical Heat Flux
is where the critical heat flux condition is characterized by a sharp reduction of local heat transfer coefficients and the excursion of wall surface temperatures. Details about this model can be found in Critical Heat Flux in the Theory Guide.

Evaporation-Condensation
allows you to select the evaporation-condensation model to use in your simulation.

Evaporation-Condensation Model Options

Lee Model
enables the Lee Model, which is the same model that is used with VOF and the mixture model. Details about this model can be found in Lee Model in the *Fluent Theory Guide*.

Thermal Phase Change
enables the thermal phase change model. Details about this model can be found in Thermal Phase Change Model in the *Fluent Theory Guide*.

Number of Discrete Phase
allows you to specify the number of discrete phases when the **Dense Discrete Phase Model** option is enabled.

Body Force Formulation
contains an additional option for body force calculations.

Implicit Body Force
enables the implicit body force treatment described in Including Body Forces (p. 1377).

VOF Sub-Models
contains additional sub-models that can be applied when using the VOF model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Open Channel Flow
enables the model to study the effects of open channel flow. See Open Channel Flow in the Theory Guide and Modeling Open Channel Flows (p. 1410) for details.

Open Channel Wave BC
enables the model to set specific parameters for a particular boundary for open channel wave boundaries. See Open Channel Wave Boundary Conditions in the Theory Guide and Modeling Open Channel Wave Boundary Conditions (p. 1419) for details.

Options
contains additional modeling options.

Interface Modeling
contains settings for how to model interfaces for the VOF model and Eulerian with Multi-Fluid VOF enabled. See Interface Modeling Type (p. 1371) for details.

Type
allows you to select the type of interface modeling to be performed. You can choose between **Sharp**, **Dispersed**, or a hybrid **Sharp/Dispersed** when both types of interfaces may be present, or when the interface is mildly sharp. See Interface Modeling Type (p. 1371) for more details.

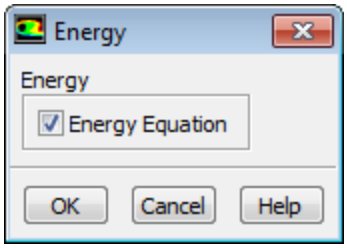
Interfacial Anti-Diffusion
enables an anti-diffusion treatment at the interface when using the **Sharp** interface modeling type. This can be used to reduce the effects of numerical diffusion that may occur with coarse meshes, high-aspect ratio cells, or large jumps in cell volume near the interface.

Interface Modeling Options...
opens the **Interface Modeling Options** dialog box from which you can enable **Zonal Discretization** and/or **Phase Localized Discretization**.

Expert Options...
opens the **Expert Options** dialog box which contains settings for VOF time advancement when using the Explicit formulation. Here you can set the **Sub-Time Step Calculation Method** and enable **Solve VOF Every Iteration**. See Expert Options (p. 1374) for details.

37.4.2. Energy Dialog Box

The **Energy** dialog box allows you to set parameters related to energy or heat transfer in your model.



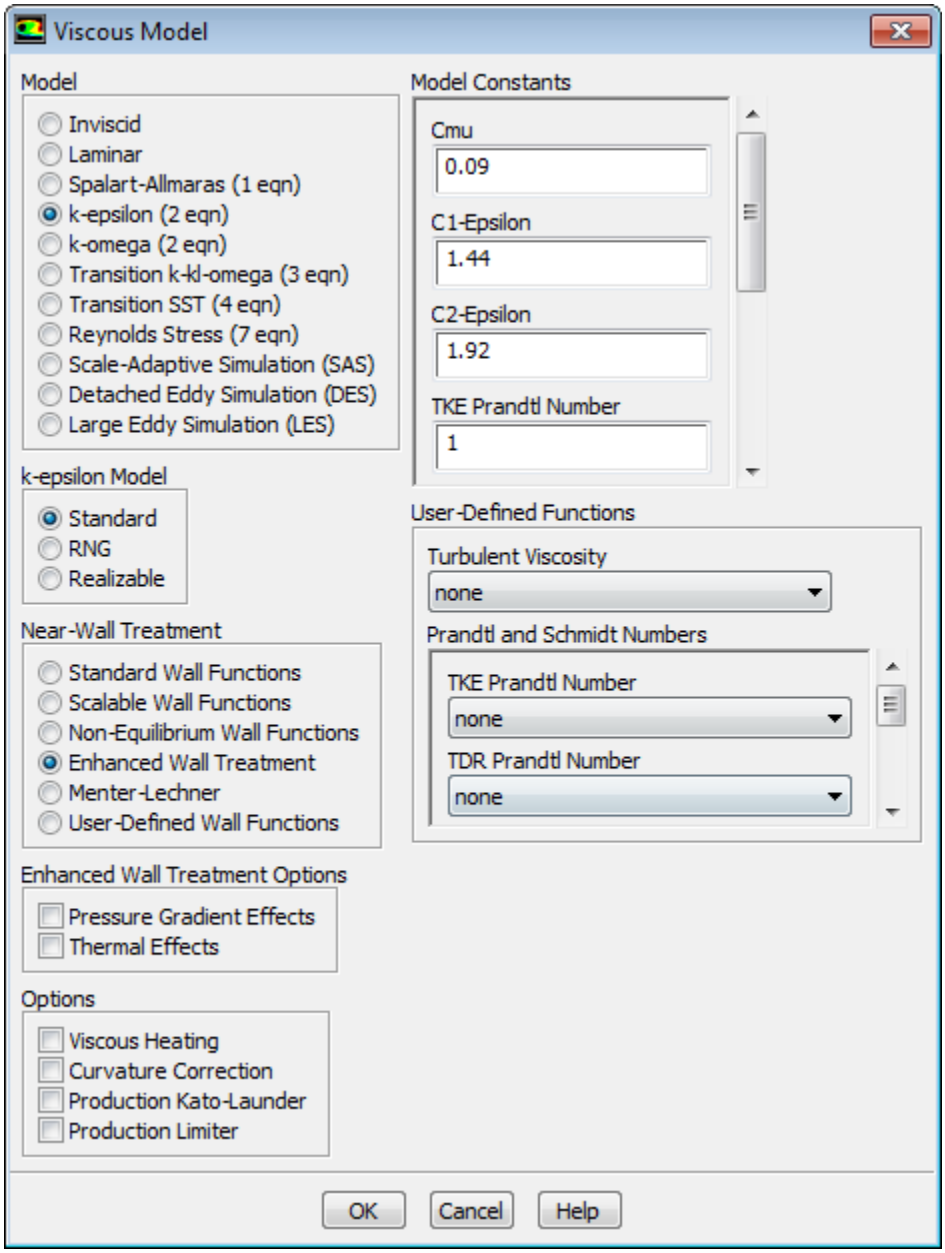
Controls

Energy
contains inputs related to the modeling of energy.

Energy Equation
enables/disables the calculation of energy in the model.

37.4.3. Viscous Model Dialog Box

The **Viscous Model** dialog box allows you to set parameters for inviscid, laminar, and turbulent flow. See Steps in Using a Turbulence Model (p. 764) for details about using this dialog box to set up a turbulent flow calculation.



Controls

Model

contains options for specifying the viscous model.

Inviscid

specifies inviscid flow.

Laminar

specifies laminar flow.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Spalart-Allmaras
specifies turbulent flow to be calculated using the Spalart-Allmaras model. (See Spalart-Allmaras Model in the Theory Guide for background about this model. See Setting Up the Spalart-Allmaras Model (p. 766) for details about using this model.)

k-epsilon
specifies turbulent flow to be calculated using one of three k-ε models. (See Standard, RNG, and Realizable k-ε Models in the Theory Guide for background about this model. See Setting Up the k-ε Model (p. 767) for details about using this model.)

k-omega
specifies turbulent flow to be calculated using one of two k-ω models. (See Standard, BSL, and SST k-ω Models in the Theory Guide for background about these models. See Setting Up the k-ω Model (p. 771) for details about using this model.)

Transition k-kl-omega
specifies turbulent flow to be calculated using the Transition k-kl-ω model. (See k-kl-ω Transition Model in the Theory Guide for background about this model. See Setting Up the Transition k-kl-ω Model (p. 775) for details about using this model.)

Transition SST
specifies turbulent flow to be calculated using the Transition SST model. (See Transition SST Model in the Theory Guide for background about this model. See Setting Up the Transition SST Model (p. 775) for details about using this model.)

Reynolds Stress
specifies turbulent flow to be calculated using the RSM. (See Reynolds Stress Model (RSM) in the Theory Guide for background about this model. See Setting Up the Reynolds Stress Model (p. 778) for details about using this model.)

Scale-Adaptive Simulation (SAS)
specifies turbulent flow to be calculated using the SAS model in combination with the SST k-ω model. (See Scale-Adaptive Simulation (SAS) Model in the Theory Guide for background about this model. See Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 781) for details about using this model.)

Detached Eddy Simulation
specifies turbulent flow to be calculated using the DES model. (See Detached Eddy Simulation (DES) in the Theory Guide for background about this model. See Setting Up the Detached Eddy Simulation Model (p. 783) for details about using this model.)

Large Eddy Simulation
(3D only) specifies turbulent flow to be calculated using the LES model. (See Large Eddy Simulation (LES) Model in the Theory Guide for background about this model. See Setting Up the Large Eddy Simulation Model (p. 792) for details about using this model.)

Spalart-Allmaras Production
contains options for the Spalart-Allmaras model. This portion of the dialog box will appear only if **Spalart-Allmaras** is selected as the **Model**.

Vorticity-Based
selects the vorticity-based calculation of the deformation tensor S (see Equation 4.22 in the Theory Guide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Strain/Vorticity-Based
selects the strain/vorticity-based calculation of the deformation tensor S (see Equation 4.24 in the Theory Guide).

k-epsilon Model
contains options for specifying which of the k-ε models is to be used. This portion of the dialog box will appear only if **k-epsilon** is selected as the **Model**.

Standard
selects the standard k-ε model, described in Standard k-ε Model in the Theory Guide and Setting Up the k-ε Model (p. 767).

RNG
selects the RNG k-ε model, described in RNG k-ε Model. in the Theory Guide and Setting Up the k-ε Model (p. 767).

Realizable
selects the realizable k-ε model, described in Realizable k-ε Model in the Theory Guide and Setting Up the k-ε Model (p. 767).

RNG Options
specifies parameters that affect the solution of problems solved with the RNG k-ε model. This portion of the dialog box will appear only if **RNG** is selected as the **k-epsilon Model**.

Differential Viscosity Model
specifies whether or not the low-Reynolds-number RNG modifications to turbulent viscosity should be included. By default, this option is turned off. It is likely to have an effect only when the near-wall regions in the domain are well resolved in terms of mesh density. See Differential Viscosity Modification (p. 800) for details.

Swirl Dominated Flow
specifies whether or not the RNG modification to turbulent viscosity for swirling flows should be included. This option is available only in 3D and 2D axisymmetric swirl solvers, and it can yield improved predictions when solving flows with significant swirl. See Swirl Modification (p. 801) for details.

k-omega Model
contains options for specifying which of the k-ω models is to be used. This portion of the dialog box will appear only if **k-omega** is selected as the **Model**.

Standard
selects the standard k-ω model, described in Standard k-ω Model in the Theory Guide and Setting Up the k-ω Model (p. 771).

BSL
selects the baseline (BSL) k-ω model, described in Baseline (BSL) k-ω Model in the Theory Guide and Setting Up the k-ω Model (p. 771).

SST
selects the shear-stress transport (SST) k-ε model, described in Shear-Stress Transport (SST) k-ω Model in the Theory Guide and Setting Up the k-ω Model (p. 771).

k-omega Options
specifies parameters that affect the solution of problems solved with the k-ω models. This portion of the dialog box will appear only if **k-omega** is selected as the **Model**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Low-Re Corrections
specifies whether corrections that improve the accuracy in predicting low Reynolds number flows should be included. This option is available only for the k-ω models and the stress-omega RSM model. See Low-Re Corrections (p. 801) for details.

Shear Flow Corrections
specifies whether corrections that improve the accuracy in predicting free shear flows should be included. This option is available only for the standard k-ω model and the stress-omega RSM model. See Shear Flow Corrections (p. 801) for details.

Turbulence Damping
is required for accurate modeling of the interfacial area. This option is available for the standard, BSL, and SST k-ω models Enter the desired **Damping Factor**, which by default is set to 10. See Turbulence Damping (p. 801) for details.

Transition SST Options
allows you to include the **Roughness Correlation** of rough walls as described in Transition SST and Rough Walls in the Theory Guide.

Roughness Correlation
when enabled allows you to specify the **Geometric Roughness Height** as a constant value.

Reynolds-Stress Model
specifies the various Reynolds stress models (RSM).

Linear Pressure-Strain
enables the linear pressure-strain model. See Linear Pressure-Strain Model in the Theory Guide for details.

Quadratic Pressure-Strain
enables the quadratic pressure-strain model for superior performance in a range of basic shear flows, including plane strain, rotating plane shear, and axisymmetric expansion/contraction. See Quadratic Pressure-Strain Model in the Theory Guide for details. Note that this option cannot be used with the **Wall Reflection Effects** option or the **Enhanced Wall Treatment**.

Stress-Omega
enables a stress-transport model that is based on the omega equations and LRR model [130] (p. 2894). This model is ideal for modeling flows over curved surfaces and swirling flows. See Stress-Omega Model in the Theory Guide for details.

Stress-BSL
enables a linear model for the pressure-strain term like the **Stress-Omega** model, but solves the scale equation from the baseline (BSL) k-ω model, and thus removes the free-stream sensitivity observed with the **Stress-Omega** model. Like the **Stress-Omega** model, it is recommended for modeling flows over curved surfaces and swirling flows. See Stress-BSL Model in the Theory Guide for details.

Reynolds-Stress Options
specifies parameters that affect the solution of problems solved with the Reynolds stress model. This portion of the dialog box will appear only if **Reynolds Stress** is selected as the **Model**.

Wall BC from k Equation
enables the explicit setting of boundary conditions for the Reynolds stresses near the walls, using the values computed with Equation 4.238 in the Theory Guide. See Solving the k Equation to Obtain Wall Boundary Conditions (p. 802) for details. This option is on by default.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Wall Reflection Effects
enables the calculation of the component of the pressure strain term responsible for the redistribution of normal stresses near the wall. See Including the Wall Reflection Term (p. 802) for details. Note that this option is not available if you have enabled the **Quadratic Pressure-Strain Model**.

RANS Model
contains options for the subgrid-scale model used by the **Detached Eddy Simulation Model**. This portion of the dialog box will appear only if **Detached Eddy Simulation Model** is selected as the **Model**.

Spalart-Allmaras
enables the Spalart-Allmaras RANS model. See Detached Eddy Simulation (DES) in the Theory Guide for details.

Realizable k-epsilon
enables the Realizable k-ε RANS model. See Detached Eddy Simulation (DES) in the Theory Guide for details.

SST k-omega
enables the SST k-ω RANS Model. See Detached Eddy Simulation (DES) in the Theory Guide for details.

DES Options
contain the option to include a delayed Detached Eddy Simulation.

Delayed DES
is useful for RANS meshes with high aspect ratios in the boundary layer. This option preserves the RANS model throughout the boundary layer. (See Delayed Detached Eddy Simulation (DDES) (p. 800) for details.)

Subgrid-Scale Model
contains options for the subgrid-scale model used by the LES model. This portion of the dialog box will appear only if **Large Eddy Simulation** is selected as the **Model**.

Smagorinsky-Lilly
selects the Smagorinsky-Lilly subgrid-scale model described in Subgrid-Scale Models in the Theory Guide.

WALE
selects the Wall-Adapting local Eddy-Viscosity model described in Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide.

WMLES
selects the algebraic Wall-Modeled LES model described in Algebraic Wall-Modeled LES Model (WMLES) in the Theory Guide.

WMLES S-Omega
selects the algebraic Wall-Modeled LES S-Ω model described in Algebraic WMLES S-Omega Model Formulation in the Theory Guide.

Kinetic-Energy Transport
selects the dynamic kinetic energy subgrid-scale model described in Dynamic Kinetic Energy Subgrid-Scale Model in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LES Model Options

contains options for the Large Eddy Simulation model. This portion of the dialog box will appear only if **Large Eddy Simulation** is selected as the **Model**.

Dynamic Stress

enables the dynamic stress model. It is available for selection when the **Smagorinsky-Lilly** is selected, and is enabled (and cannot be disabled) when the **Kinetic-Energy Transport** is selected.

Dynamic Energy Flux

enables the dynamic energy flux model. It is available when the LES model option **Dynamic Stress** is enabled.

Dynamic Scalar Flux

enables the dynamic computation of turbulent Sc (σ_t in Equation 8.5 in the Theory Guide). See Definition of the Mixture Fraction in the Theory Guide for details. It is available when the LES model option **Dynamic Stress** is enabled.

Dynamic Fvar

enables the dynamic mixture fraction variance model. It is available when **Non-Premixed Combustion** or **Partially Premixed Combustion** is selected in the Species Model Dialog Box (p. 2216). See The Non-Premixed Model for LES in the Theory Guide for details.

Near-Wall Treatment

specifies the near-wall treatment to be used for modeling turbulence. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide for details about the available methods. This portion of the dialog box will appear if **k-epsilon** or **Reynolds Stress** is selected as the **Model**.

Standard Wall Functions

enables the use of standard wall functions (described in Standard Wall Functions in the Theory Guide).

Scalable Wall Functions

enables the use of scalable wall functions (described in Scalable Wall Functions in the Theory Guide).

Non-Equilibrium Wall Functions

enables the use of non-equilibrium wall functions (described in Non-Equilibrium Wall Functions in the Theory Guide).

Enhanced Wall Treatment

enables the use of the enhanced wall treatment (described in Enhanced Wall Treatment ε-Equation (EWT-ε) in the Theory Guide). Note that this option will not appear if you have enabled the **Quadratic Pressure-Strain Model** under **Reynolds-Stress Options**.

Menter-Lechner

enables the use of the Menter-Lechner near-wall treatment (described in Menter-Lechner ε-Equation (ML-ε) in the Theory Guide). Note that this option is only available when **k-epsilon** is selected for the **Model**.

User-Defined Wall Functions

enables you to hook a user-defined function, used to define the **Law of the Wall**. See User-Defined Wall Functions in the Theory Guide for more information.

Enhanced Wall Treatment Options

allows you to include pressure gradient or thermal effects in the calculation. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pressure Gradient Effects
enables the effect of pressure gradient.

Thermal Effects
enables thermal effects in the calculation. This option appears only if the energy equation is enabled.

Options
contains general options for viscous modeling.

Viscous Heating
(if enabled) includes the viscous dissipation terms in the energy equation. This option is recommended when you are solving a compressible flow. Note that this option is always turned on when one of the density-based solvers is used; you will not be able to turn it off.

Low-Pressure Boundary Slip
includes slip boundary conditions for velocity and temperature for modeling fluid flow at very low pressures as in semiconductor fabrication devices. See Slip Boundary Formulation for Low-Pressure Gas Systems in the Theory Guide. This option is available only for laminar flows.

Full Buoyancy Effects
enables the inclusion of buoyancy effects on ε. See Including Turbulence Generation Due to Buoyancy (p. 798) for details. This option will appear if **k-epsilon** or **Reynolds Stress** is selected as the **Model** *and* a nonzero gravitational acceleration has been specified in the Operating Conditions Dialog Box (p. 2382).

Curvature Correction
when enabled, modifies the turbulence production term to sensitize the standard eddy-viscosity models to the effects of streamline curvature and system rotation. This is available for the **Spalart-Allmaras**, **k-epsilon**, **k-omega**, **Transition SST**, **Scale-Adaptive Simulation**, and **Detached Eddy Simulation** with the **SST k-omega** model.

Compressibility Effects
when enabled, can improve the prediction of free shear layers at high Mach numbers. This is available when the compressible form of the ideal gas law or the real-gas model is activated for **k-epsilon**, **k-omega**, **Transition k-kl-omega**, **Reynolds Stress**, **Scale-Adaptive Simulation**, and **Detached Eddy Simulation** with the **Realizable k-epsilon** model. For details, see Model Enhancements (p. 755).

Mixture Drift Force
includes the effect of turbulent drift velocity when using the **Mixture** model. See Modeling Turbulence (p. 1474). Note that this option is only available when using the **Mixture** model with **Slip Velocity** enabled in the **Multiphase Model** dialog box. See Including Mixture Drift Force (p. 1454).

Production Kato-Launder
when enabled, the Kato-Launder modification for the production term limits the production term in the turbulence equation. For details see, Production Limiters for Two-Equation Models in the *Fluent Theory Guide*.

Production Limiter
when enabled, limits the production term in the turbulence equation. For details, see Production Limiters for Two-Equation Models in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Intermittency Transition Model
enables the Intermittency Transition model to account for transitional effects. This option is only available for the BSL k-ω, SST k-ω, Scale-Adaptive Simulation with BSL / SST, and Detached Eddy Simulation with BSL / SST models. For details, see Intermittency Transition Model in the Theory Guide.

Intermittency Transition Options
contains an option for the Intermittency Transition model. This group box is only available when the **Intermittency Transition Model** option is enabled.

Include Crossflow Transition
includes the effects of crossflow instability. For details, see Transport Equations for the Intermittency Transition Model in the Theory Guide.

Turbulence Multiphase Model
contains options for multiphase turbulence models. This portion of the dialog box will appear if **Eulerian** is selected as the **Model** in the Multiphase Model Dialog Box (p. 2171).

Mixture
specifies the (default) mixture turbulence model.

Dispersed
specifies the dispersed turbulence model.

Per Phase
specifies the calculation of a set of turbulence equations for each phase.

See Turbulence Models in the Theory Guide for details about the available multiphase turbulence models.

Model Constants
contains constants used in the equations for turbulence. See Spalart-Allmaras Model, Standard k-ε Model, RNG k-ε Model, k-kl-ω Transition Model, Transition SST Model, Realizable k-ε Model, Reynolds Stress Model (RSM), Standard k-ω Model, Shear-Stress Transport (SST) k-ω Model, and Large Eddy Simulation (LES) Model in the Theory Guide for details about these constants.

Cb1
(only for the Spalart-Allmaras model) is the constant C_{b1} in Equation 4.19 in the Theory Guide.

Cb2
(only for the Spalart-Allmaras model) is the constant C_{b2} in Equation 4.15 in the Theory Guide.

Cv1
(only for the Spalart-Allmaras model) is the constant C_{v1} in Equation 4.17 in the Theory Guide.

Cw2
(only for the Spalart-Allmaras model) is the constant C_{w2} in Equation 4.28 in the Theory Guide.

Cw3
(only for the Spalart-Allmaras model) is the constant C_{w3} in Equation 4.27 in the Theory Guide.

Cprod
(only for the Spalart-Allmaras model when the **Strain/Vorticity-Based Production** option is used) is the constant C_{prod} in Equation 4.24 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cmu
(only for the standard or RNG k-ε model, the RSM, or the k-kl-ω Transition model) is the constant C_μ that is used to compute μ_t.

C1-Epsilon
(only for the standard or RNG k-ε model or the RSM) is the constant $C_{1\varepsilon}$ used in the transport equation for ε.

C2-Epsilon
(only for the standard, RNG, or realizable k-ε model or the RSM) is the constant $C_{2\varepsilon}$ used in the transport equation for ε.

C3-Epsilon
(only for the dispersed or per-phase k-ε multiphase models) is the constant $C_{3\varepsilon}$ in Equation 17.358 in the Theory Guide.

C-lambda
(only for the k-kl-ω Transition model) is the constant C_λ in the definition of the effective length,

CR
(only for the k-kl-ω Transition model) is the constant C_R used in the definition of R, where R represents the averaged effect of the breakdown of streamwise fluctuations into turbulence during bypass transition

ANAT
(only for the k-kl-ω Transition model) is the constant A_{NAT}

ATS
(only for the k-kl-ω Transition model) is the constant A_{TS}

CNAT, crit
(only for the k-kl-ω Transition model) is the constant $C_{NAT,crit}$

CTS, crit
(only for the k-kl-ω Transition model) is the constant $C_{TS,crit}$

CRNAT
(only for the k-kl-ω Transition model) is the constant $C_{R,NAT}$

Anu
(only for the k-kl-ω Transition model) is the constant A_ν

CINT
(only for the k-kl-ω Transition model) is the constant C_{INT}

Cw1
(only for the k-kl-ω Transition model) is the constant $C_{\omega 1}$

Cw3
(only for the k-kl-ω Transition model) is the constant $C_{\omega 3}$

Calpha-teta
(only for the k-kl-ω Transition model) is the constant $C_{\alpha,\theta}$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ctaul
(only for the k-kl-ω Transition model) is the constant $C_{\tau,1}$

SDR Prandtl Number
(only for the standard k-ω model and the k-kl-ω Transition model) is the effective "Prandtl" number for the transport of the specific dissipation rate, σ_ω.

Ca1
(only for the Transition SST model)

Ca2
(only for the Transition SST model)

Ce1
(only for the Transition SST model)

Ce2
(only for the Transition SST model)

C_thetat
(only for the Transition SST model)

C_s1
(only for the Transition SST model)

Intermit. Prandtl #)
(only for the Transition SST model)

Re_theta. Prandtl #)
(only for the Transition SST model)

C Shielded DES
(only for the SDES or SBES model) is a constant that serves the same purpose as C_{d1} in the DDES turbulence model (see Equation 4.262 in the Theory Guide).

Csdes
(only for the SDES or SBES model) is C_{SDES}, as described in Shielded Detached Eddy Simulation (SDES) in the Theory Guide.

Cwale
(only for the WALE subgrid-scale model of the LES or SBES model) is C_w, as described in Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide.

Swirl Factor
sets the value of α_s in Equation 4.46 in the Theory Guide. This item appears for the RNG k-ε model when the **Swirl Dominated Flow** option is turned on.

Alpha*_inf
(only for the standard, BSL, or SST k-ω model, and the Transition SST model) is the constant α^*_∞ in Equation 4.74 in the Theory Guide.

Alpha_inf
(only for the standard, BSL, or SST k-ω model, and the Transition SST model) is the constant α_∞ in Equation 4.82 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alpha_0
(only for the standard, BSL, or SST k-ω model with the **Low-Re Corrections** option enabled) is the constant α_0 in Equation 4.82 in the Theory Guide.

Beta*_inf
(only for the standard, BSL, or SST k-ω model, and the Transition SST model) is the constant β^*_∞ in Equation 4.87 in the Theory Guide.

Beta_i
(only for the standard k-ω model) is the constant β_i in Equation 4.95 in the Theory Guide.

R_beta
(only for the standard, BSL, or SST k-ω model) is the constant R_β in Equation 4.87 in the Theory Guide.

R_k
(only for the standard, BSL, or SST k-ω model with the **Low-Re Corrections** option enabled) is the constant R_k in Equation 4.74 in the Theory Guide.

R_w
(only for the standard, BSL, or SST k-ω model with the **Low-Re Corrections** option enabled) is the constant R_ω in Equation 4.82 in the Theory Guide.

Zeta*
(only for the standard, BSL, or SST k-ω model when the **Compressibility Effects** option is enabled) is the constant ζ^* in Equation 4.86 in the Theory Guide.

Mt0
(only for the standard, BSL, or SST k-ω model when the **Compressibility Effects** option is enabled) is the constant M_{t0} in Equation 4.96 in the Theory Guide.

a1
(only for the SST k-ω model, and the Transition SST model) is the constant a_1 in Equation 4.117 in the Theory Guide.

Beta_i (Inner)
(only for the BSL or SST k-ω model, and the Transition SST model) is the constant $\beta_{i,1}$ in Model Constants in the Theory Guide.

Beta_i (Outer)
(only for the BSL or SST k-ω model, and the Transition SST model) is the constant $\beta_{i,2}$ in Model Constants in the Theory Guide.

Cs
is a constant that depends on the turbulence model. For LES, it is the Smagorinsky constant C_s in Equation 4.285 in the Theory Guide. For SAS, it is the high wave number damping coefficient C_S in Equation 4.248 in the Theory Guide.

C1-PS
(only for RSM) is the constant C_1 in Equation 4.209 in the Theory Guide.

C2-PS
(only for RSM) is the constant C_2 in Equation 4.210 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

C1′-PS

(only for RSM) is the constant $C_1^{'}$ in Equation 4.211 in the Theory Guide.

C2′-PS

(only for RSM) is the constant $C_2^{'}$ in Equation 4.211 in the Theory Guide.

C1-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_1 in Equation 4.220 in the Theory Guide.

C1′-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_1^* in Equation 4.220 in the Theory Guide.

C2-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_2 in Equation 4.220 in the Theory Guide.

C3-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_3 in Equation 4.220 in the Theory Guide.

C3′-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_3^* in Equation 4.220 in the Theory Guide.

C4-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_4 in Equation 4.220 in the Theory Guide.

C5-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_5 in Equation 4.220 in the Theory Guide.

Prandtl Number

(only for the Spalart-Allmaras model) is the constant $\sigma_{\tilde{\nu}}$ in Equation 4.15 in the Theory Guide.

TKE Prandtl Number

(only for the standard or realizable k-ε model, the standard k-ω model, the k-kl-ω Transition model, or the RSM) is the effective "Prandtl" number for transport of turbulence kinetic energy σ_k. This effective Prandtl number defines the ratio of the momentum diffusivity to the diffusivity of turbulence kinetic energy via turbulent transport.

TKE (Inner) Prandtl #

(only for the BSL or SST k-ω model, and the Transition SST model) is the effective "Prandtl" number for the transport of turbulence kinetic energy, $\sigma_{k,1}$, inside the near-wall region. See Modeling the Turbulent Viscosity in the Theory Guide for details.

TKE (Outer) Prandtl #

(only for the BSL or SST k-ω model, and the Transition SST model) is the effective "Prandtl" number for the transport of turbulence kinetic energy, $\sigma_{k,2}$, outside the near-wall region. See Modeling the Turbulent Viscosity in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

TDR Prandtl Number
is the effective "Prandtl" number for transport of the turbulent dissipation rate, σ_ε, for the standard or realizable k-ε model or the RSM. This effective Prandtl number defines the ratio of the momentum diffusivity to the diffusivity of turbulence dissipation via turbulent transport.

SDR (Inner) Prandtl #
(only for the BSL or SST k-ω model, and the Transition SST model) is the effective "Prandtl" number for the transport of the specific dissipation rate, $\sigma_{\omega,1}$, inside the near-wall region. See Modeling the Turbulent Viscosity in the Theory Guide for details.

SDR (Outer) Prandtl #
(only for the BSL or SST k-ω model, and the Transition SST model) is the effective "Prandtl" number for the transport of the specific dissipation rate, $\sigma_{\omega,2}$, outside the near-wall region. See Modeling the Turbulent Viscosity in the Theory Guide for details.

Dispersion Prandtl Number
(only for the k-ε multiphase models) is the effective "Prandtl" number for the dispersed phase, σ_{pq}. See Turbulence Models in the Theory Guide for details.

Energy Prandtl Number
(for any turbulence model except the RNG k-ε model) is the turbulent Prandtl number for energy, Pr_t, in Equation 4.228 in the Theory Guide. (This item will not appear for the LES model if the **Dynamic Energy Flux** option has been enabled, or for premixed or partially premixed combustion models.) For non-premixed and partially premixed combustion, the energy Prandtl Number is set equal to the PDF Schmidt Number.

Wall Prandtl Number
(for all turbulence models) is the turbulent Prandtl number at the wall, Pr_t in Equation 4.319 in the Theory Guide. (This item will not appear for adiabatic premixed combustion or partially premixed combustion models.)

Turbulent Schmidt Number
(for turbulent species transport calculations using any turbulence model except the RNG k-ε model) is the turbulent Schmidt number, Sc_t, in Equation 7.3 in the Theory Guide. (This item will not appear for the LES model if the **Dynamic Scalar Flux** option has been enabled.)

PDF Schmidt Number
(for non-premixed or partially premixed combustion calculations using any turbulence model) is the model constant σ_t in Equation 8.5 in the Theory Guide.

Production Limiter Clip Factor
This coefficient is used by the **Production Limiter**. For details, see Equation 4.382 in the *Fluent Theory Guide*.

User-Defined Transition Correlations
(only for the Transition SST model) allows you to select the user-defined correlations for **F_length**, **Re_thetac**, **Re_thetat**.

User-Defined Functions
allows you to select the user-defined functions for various constants.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Turbulent Viscosity
appears for Spalart Allmaras, k-ε, k-ω, DES, SDES with BSL / SST models, and SBES with BSL / SST. You can select the user-defined functions for turbulent viscosity in the drop-down list.

Prandtl Numbers, Prandtl and Schmidt Numbers
contains a list of relevant Prandtl and Schmidt numbers for which you can select user-defined functions.

TKE Prandtl Number
allows you to select a user-defined function to define the TKE Prandtl number for the standard and realizable k-ε models and the standard k-ω model.

TDR Prandtl Number
allows you to select a user-defined function to define the TDR Prandtl number for the standard and realizable k-ε models.

Energy Prandtl Number
allows you to select a user-defined function to define the turbulent Prandtl number for energy, when energy is enabled for all turbulence models except the RNG k-ε model. (This item will not appear for the LES model if the **Dynamic Energy Flux** option has been enabled.)

Wall Prandtl Number
allows you to select a user-defined function to define the turbulent Prandtl number at the wall for all turbulence models when energy is enabled.

Turbulent Schmidt Number
allows you to select a user-defined function to define the turbulent Schmidt number when species transport is enabled for all turbulence models except the RNG k-ε model. (This item will not appear for the LES model if the **Dynamic Scalar Flux** option has been enabled.)

SDR Prandtl Number
allows you to select a user-defined function to define the SDR Prandtl number for the standard k-ω model.

Subgrid-Scale Turbulent Viscosity
allows you to select a user-defined function for the subgrid-scale turbulent viscosity for the LES model.

Scale-Resolving Simulation Options
allows you to combine two turbulence models, which are applied on the appropriate regions of the flow domain. For additional information, see Scale-Resolving Simulation (SRS) Models (p. 756).

Scale-Adaptive Simulation (SAS)
allows you to apply SAS in combination with the following ω-based URANS models: the Standard or BSL k-ω model, the Transition SST model, and the ω-based Reynolds stress models. For additional information, see Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 781).

Detached Eddy Simulation (DES)
allows you to apply DES in combination with the BSL k-ω model and Transition SST model. For additional information, see Detached Eddy Simulation (DES) (p. 758).

Stress Blending (SBES) / Shielded DES
allows you to apply SBES or SDES in combination with the BSL k-ω model, SST k-ω model, and Transition SST model. See Stress-Blended Eddy Simulation (SBES) and Shielded Detached Eddy Simulation (SDES) in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Shielding Functions

allows you to select the shielding functions (**SST F1 Function**, **SST F2 Function**, **DDES**, and **IDDES**) for the Detached Eddy Simulation model with the BSL k-ω model, SST k-ω model, and Transition SST model. (see Shielding Functions for the BSL / SST / Transition SST Detached Eddy Simulation Model (p. 807) for details).

SBES / SDES Options

allows you to define the following settings as part of the SBES or SDES model:

Hybrid Model

specifies that the hybrid RANS-LES model used is either **SDES** (Shielded DES model), **SBES** (Stress-Blended Eddy Simulation model), or **SBES with User-Defined Function**. See Including the SDES or SBES Model with BSL, SST, and Transition SST Models (p. 805) for details.

Subgrid-Scale Model

contains options for the subgrid-scale model used in the LES region of your Stress-Blended Eddy Simulation. This portion of the dialog box will appear only if **SBES** or **SBES with User-Defined Function** is selected as the **Hybrid Model**.

Smagorinsky-Lilly

selects the Smagorinsky-Lilly subgrid-scale model described in Subgrid-Scale Models in the Theory Guide.

Dynamic Smagorinsky

selects the Smagorinsky-Lilly subgrid-scale model (described in Subgrid-Scale Models in the Theory Guide) with the dynamic stress model enabled.

WALE

selects the Wall-Adapting local Eddy-Viscosity model described in Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide.

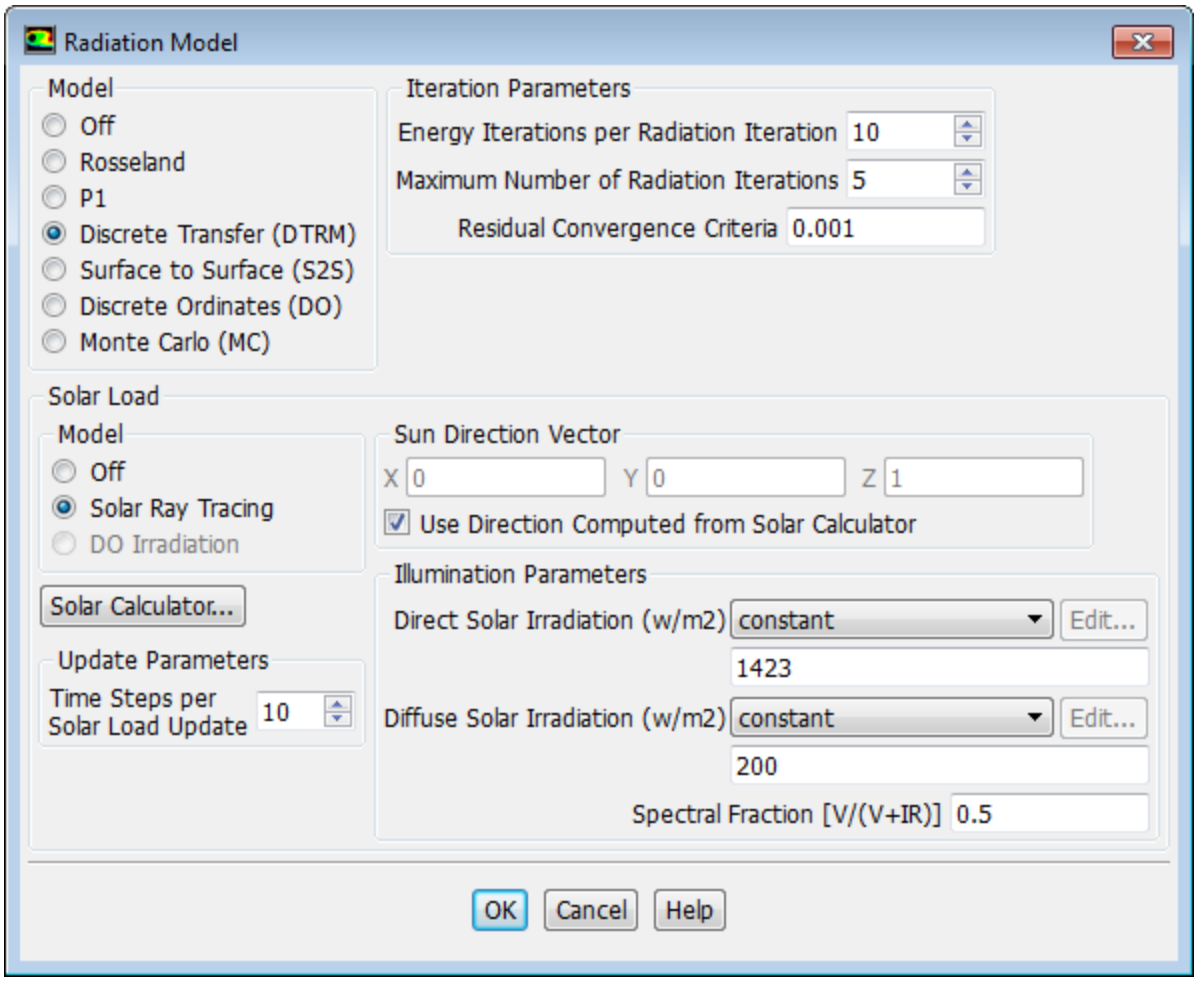
WMLES S-Omega

selects the algebraic Wall-Modeled LES S-Ω model described in Algebraic WMLES S-Omega Model Formulation in the Theory Guide.

37.4.4. Radiation Model Dialog Box

The **Radiation Model** dialog box allows you to select a model for radiation heat transfer and set the associated parameters. See Using the Radiation Models (p. 845) – Defining Non-Gray Radiation for the DO Model (p. 865) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

indicates which model, if any, is used to calculate radiation heat transfer. See Modeling Radiation (p. 845) for details about modeling radiation heat transfer.

Off

disables the calculation of radiation heat transfer.

Rosseland

enables the Rosseland radiation model.

P1

enables the P-1 radiation model.

Discrete Transfer (DTRM)

enables the discrete transfer radiation model (DTRM).

Surface to Surface (S2S)

enables the surface-to-surface (S2S) radiation model.

Discrete Ordinates (DO)

enables the discrete ordinates (DO) radiation model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Monte Carlo (MC)
enables the Monte Carlo (MC) radiation model.

DO/Energy Coupling
allows you to couple the energy and DO intensity equations at each cell, solving them simultaneously. See Defining Non-Gray Radiation for the DO Model (p. 865) for details.

Iteration Parameters
contains parameters related to the DTRM, S2S, and the DO models. This portion of the dialog box will appear only if **Discrete Transfer (DTRM)**, **Surface to Surface (S2S)**, or **Discrete Ordinates (DO)** is selected as the **Model**.

Energy Iterations per Radiation Iteration
controls the frequency with which the radiation terms are updated as the continuous phase solution proceeds. The **Energy Iterations per Radiation Iteration** parameter is set to 10 by default. This implies that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence.

Maximum Number of Radiation Iterations
controls the maximum number of iterations of the radiation calculation during each global iteration. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

This item appears only when **Discrete Transfer** or **Surface to Surface** is selected as the **Model**.

Residual Convergence Criteria
determines when the radiation intensity update is converged. It is defined as the maximum normalized change in the surface intensity from one radiation iteration to the next (see Equation 12.9 (p. 881)).

This item appears only when **Discrete Transfer** or **Surface to Surface** is selected as the **Model**.

Target Number of Histories
determines the number of photon histories to be tracked for the Monte Carlo simulation. Too small of a number will produce "speckled" results. Increasing the target number of histories produces a smoother and more accurate solution, but at the expense of higher computation effort.

This item appears only when **Monte Carlo** is selected.

View Factors and Clustering
contains parameters related to the S2S model. This portion of the dialog box will appear only if **Surface to Surface** is selected as the **Model**. See Setting Up the S2S Model (p. 851) for more information about the use of these parameters.

Settings...
opens the View Factors and Clustering Dialog Box (p. 2194), in which you can set parameters related to surface clusters and view factors.

Compute/Write/Read...
allows you to compute the view factors, write the computed view factors to a file, and read the file into ANSYS Fluent. When you click **Compute/Write/Read...**, The Select File Dialog Box (p. 19) will open so that you can specify a name for the file where ANSYS Fluent should save the view factors after computing them, and indicate whether the files should be saved in binary format.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Read Existing File...
opens The Select File Dialog Box (p. 19), in which you can specify the file from which ANSYS Fluent should read view factors.

Angular Discretization
contains parameters for angular discretization and pixelation for the DO model. This portion of the dialog box will appear only if **Discrete Ordinates** is selected as the **Model**. See Setting Up the DO Model (p. 864) for more information about the use of these parameters.

Theta Divisions, Phi Divisions
define the number of control angles used to discretize each octant of the angular space (see Figure 5.3: Angular Coordinate System in the Theory Guide).

Theta Pixels, Phi Pixels
are used to control the pixelation that accounts for any control volume overhang (see Figure 5.7: Pixelation of Control Angle in the Theory Guide and the figures and discussion preceding it).

Radiation Mesh Options
This portion of the dialog box will appear only if the **Monte Carlo** model is selected.

Mesh Coarsening
Coarsens the radiation mesh used by the MC model. See Setting Up the MC Model (p. 867) for more information about the use of this parameter.

Non-Gray Model
contains parameters related to the non-gray P-1, DO, or MC model. This portion of the dialog box will appear only if **P1**, **Discrete Ordinates**, or **Monte Carlo** is selected as the **Model**. See Setting Up the P-1 Model with Non-Gray Radiation (p. 847) or Defining Non-Gray Radiation for the DO Model (p. 865) for more information about the use of these parameters.

Number of Bands
specifies the number of bands for the non-gray radiation.

Wavelength Intervals (n=1)
contains inputs that define each wavelength band. (It appears only when the **Number of Bands** is nonzero.) For each band, you can specify a **Name**, as well as the **Start** and **End** wavelength of the band in μm. Note that the wavelength bands are specified for vacuum (n=1). ANSYS Fluent will automatically account for the refractive index in setting band limits for media with n different from unity.

Solar Load
contains parameters related to solar load model that can be used to calculate radiation effects from the sun's rays that enter a computational domain. It is available only for the 3D version of ANSYS Fluent. See Solar Load Model (p. 886) for more information about the use of these parameters.

Model
indicates which model is used to calculate radiation effects.

Off
disables the calculation of solar radiations.

Solar Ray Tracing
enables the solar ray tracing algorithm

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DO Irradiation
enables the DO irradiation option. Select **Discrete Ordinates** under **Model** before selecting this option.

Solar Calculator
opens the Solar Calculator Dialog Box (p. 2199).

Sun Direction Vector
contains the components of sun direction vector.

X, Y, Z
are the components of the sun direction vector.

Use Direction Computed from Solar Calculator
enables the use of direction vector computed from the solar calculator.

Illumination Parameters
contains illumination options.

Direct Solar Irradiation
is the amount of energy per unit area due to direct solar irradiation.

Diffuse Solar Irradiation
is the amount of energy per unit area due to diffuse solar irradiation.

Spectral Fraction
is the fraction of incident solar radiation in the visible part of the solar radiation spectrum. The spectral fraction is not used for DO irradiation since the DO implementation is intended only for a single band. This parameter is available only for **Solar Ray Tracing**.

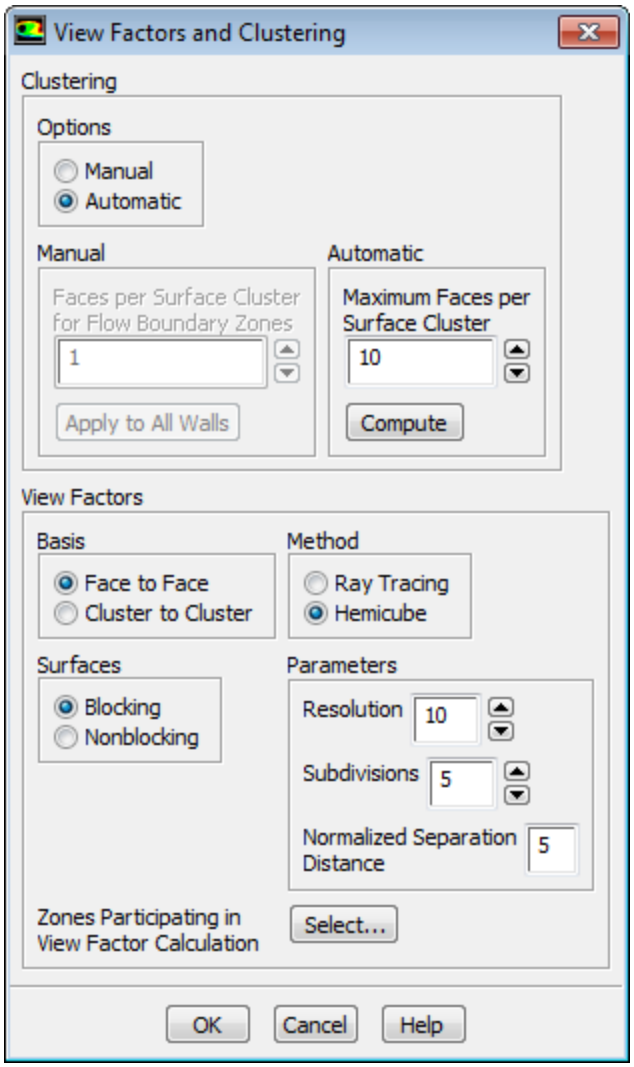
Update Parameters
contains update parameters for transient simulations.

Time Steps per Solar Load Update
specifies the number of time steps that will direct the ANSYS Fluent solver to update the solar load data for the specified flow-time intervals in the unsteady solution process.

37.4.5. View Factors and Clustering Dialog Box

The **View Factors and Clustering** dialog box allows you to set parameters related to surface clusters and view factors for the surface-to-surface radiation model. See Setting Up the S2S Model (p. 851) for information about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Clustering

contains the methods and settings for creating surface clusters. See Forming Surface Clusters (p. 853) for information about surface cluster settings.

Options

gives you a choice of forming clusters either manually or automatically.

Manual

allows you to form clusters manually.

Automatic

allows ANSYS Fluent to form the cluster automatically.

Manual

(available only when the **Manual** option is enabled) allows you to set the faces per surface cluster (FPSC) value for walls and inlet and outlet boundaries.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Faces per Surface Cluster for Flow Boundary Zones

specifies the number of faces in each surface cluster for inlet and outlet boundaries (that is, exhaust fan, inlet vent, intake fan, outlet vent, mass-flow inlet, mass-flow outlet, pressure far-field, pressure inlet, pressure outlet, outflow, and velocity inlet boundaries). This FPSC value can also be applied to all walls that are adjacent to fluid zones by clicking the **Apply to All Walls** button. The default is set to `1`. See Clustering in the Theory Guide for details about clustering.

Apply to All Walls

applies the value specified in the **Faces per Surface Cluster for Flow Boundary Zones** field to all walls that are adjacent to fluid zones.

Automatic

(available only when the **Automatic** option is enabled) allows you to assign different faces per surface cluster (FPSC) values to the walls automatically, based on the distance of the walls from and the FPSC values of the walls that are defined as critical.

Maximum Faces per Surface Cluster

specifies the maximum number of faces per surface cluster automatically assigned to non-critical wall zones adjacent to fluid zones. The default is set to `10`.

Compute

results in ANSYS Fluent automatically calculating and updating the face per surface cluster values in the boundary conditions dialog box for non-critical wall zones adjacent to fluid zones, without computing the clusters.

View Factors

contains settings for computing the view factors. See Setting Up the View Factor Calculation (p. 856) for information about view factor calculation settings.

Basis

specifies how surfaces are defined for the calculation of view factors. See Selecting the Basis for Computing View Factors (p. 856) for more information.

Face to Face

specifies that the surfaces used to calculate the view factors are the boundary faces.

Cluster to Cluster

specifies that the surfaces used to calculate the view factors are the clusters defined by the settings in the **Clustering** group box. The cluster to cluster basis is only available for 3D cases.

Surfaces

specifies the geometric orientation of surface pairs with respect to each other when using the hemicube method.

Blocking

specifies that the view factor calculation accounts for surfaces that block the views between the surfaces under consideration.

Nonblocking

specifies that the view factor calculation does not account for surfaces that block the views between the surfaces under consideration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Method
specifies the method for computing the view factors. See Selecting the Method for Computing View Factors (p. 857) for information about choosing a method.

Hemicube
specifies the use of the hemicube method for computing the view factors. The hemicube method is available only for 3D and axisymmetric cases, and should not be used if any of the zones are defined as periodic or symmetry boundaries.

Ray Tracing
specifies the use of the ray tracing method for computing the view factors. For 2D cases, the number of rays used with this method is two times the value set for **Resolution** in the **Parameters** group box; for 3D cases, the number of rays is three times the square of the **Resolution** value.

Parameters
contains settings related to the hemicube and ray tracing methods for computing the view factors. All of these inputs are available when **Hemicube** is selected under **Method**, whereas only **Resolution** is available when **Ray Tracing** is selected. See Selecting the Method for Computing View Factors (p. 857) for information about setting the method parameters.

Resolution
specifies the resolution of the hemicube. The default value is set to `10`. You can increase the value to reduce aliasing effects that can lead to overestimated or underestimated view factors.

Subdivisions
specifies the number of subfaces into which each face is divided. The default value is set to 5. This parameter is only available when the hemicube method is used in conjunction with the face to face basis.

Normalized Separation Distance
specifies the ratio of the minimum face separation to the effective diameter of the face. The default value is set to 5. This parameter is only available for the hemicube method.

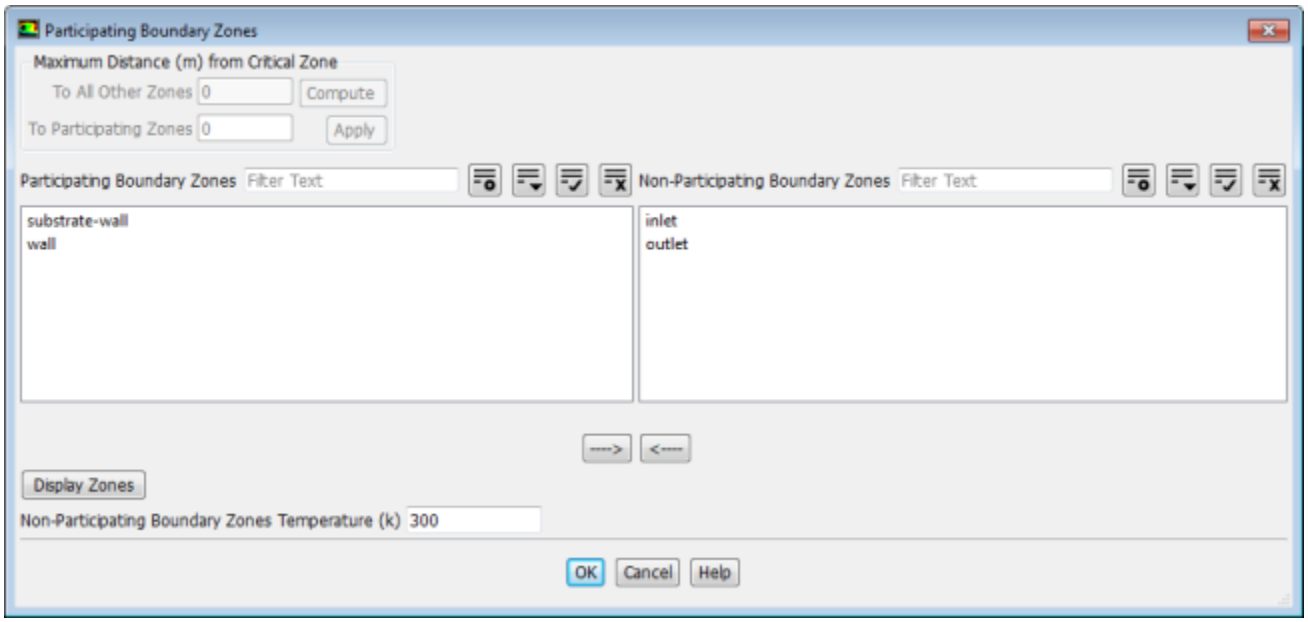
Zones Participating in View Factor Calculation
allows you to define which boundary zones participate in the view factor calculation. See Specifying Boundary Zone Participation (p. 858) for more information.

Select...
opens the Participating Boundary Zones Dialog Box (p. 2197), where you can define which boundary zones participate in the view factor calculation.

37.4.6. Participating Boundary Zones Dialog Box

The **Participating Boundary Zones** dialog box allows you to define which boundary zones participate in the view factor calculation, to display zones in the graphics window, and set the temperature of zones that do not participate in the view factor calculation. See Specifying Boundary Zone Participation (p. 858) for details. This dialog box opens when you click the **Select...** button next to the **Zones Participating in View Factor Calculation** label in the **View Factors and Clustering** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Maximum Distance from Critical Zone
allows you to view the maximum distance between critical zones and other zones, and set all boundary zones that are located beyond a certain distance from a critical zone as not participating in the view factor calculation.

To All Other Zones
displays the maximum of the distances between the centroids of critical and all other wall, inlet, and exit zones when the **Compute** button is clicked. This field is not editable. This is only available when using the **Automatic** option for clustering.

Compute
calculates the distances between the centroids of critical zones and all the other wall, inlet, and exit zones and displays the maximum value in the **To All Other Zones** field and the **To Participating Zones** text-entry box. It requires the definition of the critical zone.

To Participating Zones
displays the maximum of the distances between the centroids of critical and all other wall, inlet, and exit zones when the **Compute** button is clicked. Unlike the **To All Other Zones** field, you can edit this text-entry box. You can specify the maximum distance allowed between the centroids of critical zones and all other wall, inlet, or exit zones that participate in the view factor calculation; when you click the **Apply** button, all of the zones will be marked as either participating or not participating, according to the distance criteria you specified. Note that this field is only available when using the **Automatic** option for clustering.

Apply
marks all of the wall, inlet, and exit zones as either participating or not participating in the view factor calculation, depending on whether the distance from their centroid to the centroid of a critical zone is equal to or less than value entered for **To Participating Zones**. The **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists will be updated accordingly.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Participating Boundary Zones
shows all the zones that are participating in the view factor calculation. You can select a zone and click the arrow button that points to the right to move the zone to the **Non-Participating Boundary Zones** list.

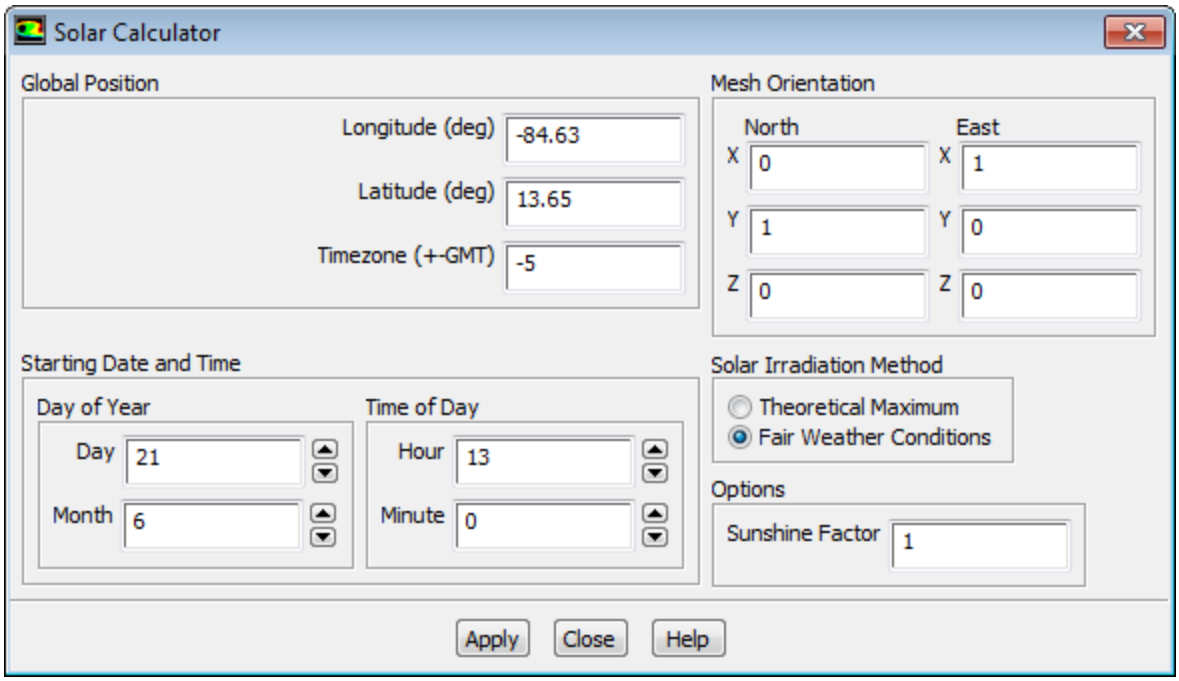
Non-Participating Boundary Zones
shows all the zones that are not participating in the view factor calculation. You can select a zone and click the arrow button that points to the left to move the zone to the **Participating Boundary Zones** list.

Display Zones
displays any zones selected in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists in the graphics window.

Non-Participating Boundary Zones Temperature
allows you to specify the temperature of the zones that do not participate in the view factor calculation.

37.4.7. Solar Calculator Dialog Box

The **Solar Calculator** dialog box allows you to set parameters related to the calculation of solar load models. See Solar Load Model (p. 886) for details. This dialog box opens when you click the **Solar Calculator...** button in the **Radiation Model** dialog box.



Controls

Global Position
contains the parameters to define the position of solar radiation.

Longitude
specifies the longitude of the desired location in degrees. Values may range from -180 to 180, where negative values indicate the Western hemisphere and positive values indicate the Eastern hemisphere.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Latitude
specifies the latitude of the desired location in degrees. Values may range from -90 (South pole) to 90 (North pole) with 0 defined as the equator.

Timezone
specifies the local time zone of the desired location in hours relative to Greenwich Mean Time (+-GMT). This integer value can range from 12 to -12.

Starting Date and Time
contains parameters to specify date and time.

Day of Year
contains parameters to specify day and month.

Time of Day
contains parameters to specify hour and minutes.

Mesh Orientation
specifies the orientation as the vectors for North and East in the CFD grid system of coordinates.

Solar Irradiation Method
contains parameters to choose the solar irradiation method.

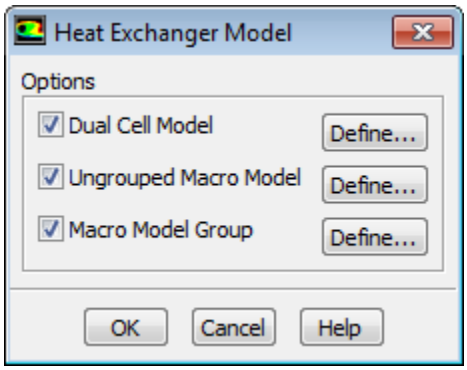
Theoretical Maximum
enables theoretically maximum solar irradiation method.

Fair Weather Conditions
enables fair weather condition solar irradiation method.

Sunshine Factor
is a linear reduction factor for the computed incident load that allows for cloud cover to be accounted for, if appropriate.

37.4.8. Heat Exchanger Model Dialog Box

The **Heat Exchanger Model** dialog box allows you to define a heat exchanger as part of your model. See Modeling Heat Exchangers (p. 919) for details about using the items below.



Controls

Options
contains options related to the heat exchanger model. See Choosing a Heat Exchanger Model (p. 920) for details about the differences between the models associated with these options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

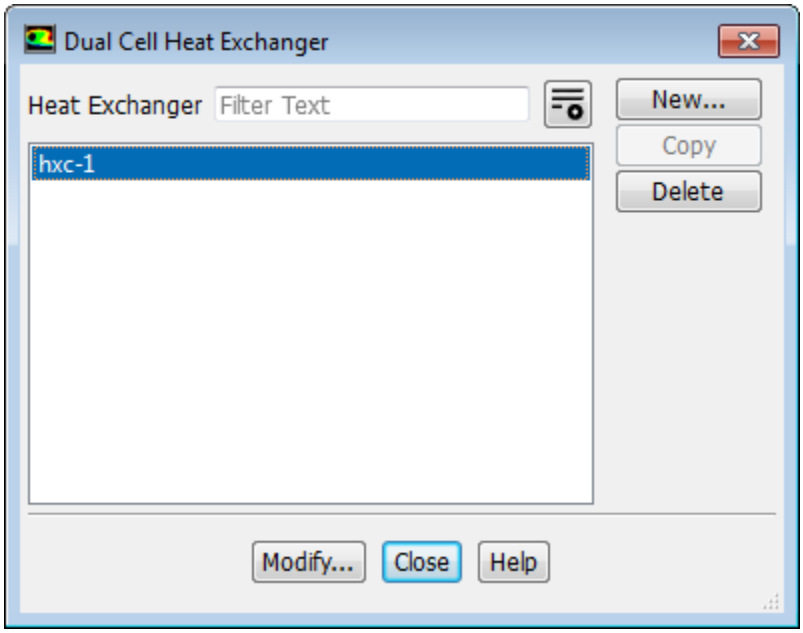
Dual Cell Model
allows you to enable or disable the Dual Cell heat exchanger model. When this option is enabled, the corresponding **Define...** button opens the Dual Cell Heat Exchanger Dialog Box (p. 2201).

Ungrouped Macro Model
allows you to enable or disable the Ungrouped Macro heat exchanger model. When this option is enabled, the corresponding **Define...** button opens the Ungrouped Macro Heat Exchanger Dialog Box (p. 2207).

Macro Model Group
allows you to enable or disable the Macro heat exchanger group model. When this option is enabled, the corresponding **Define...** button opens the Macro Heat Exchanger Group Dialog Box (p. 2212).

37.4.9. Dual Cell Heat Exchanger Dialog Box

The **Dual Cell Heat Exchanger** dialog box allows you to use the NTU method for heat transfer calculations. This model allows the solution of auxiliary flow on a separate mesh (other than the primary fluid mesh). See Using the Dual Cell Heat Exchanger Model (p. 922) for information about using this dialog box.



Controls

Heat Exchanger
contains a list of predefined heat exchangers.

New...
opens the Set Dual Cell Heat Exchanger Dialog Box (p. 2202).

Copy
opens the Copy From Dialog Box (p. 2206), which allows you to copy the currently selected heat exchanger.

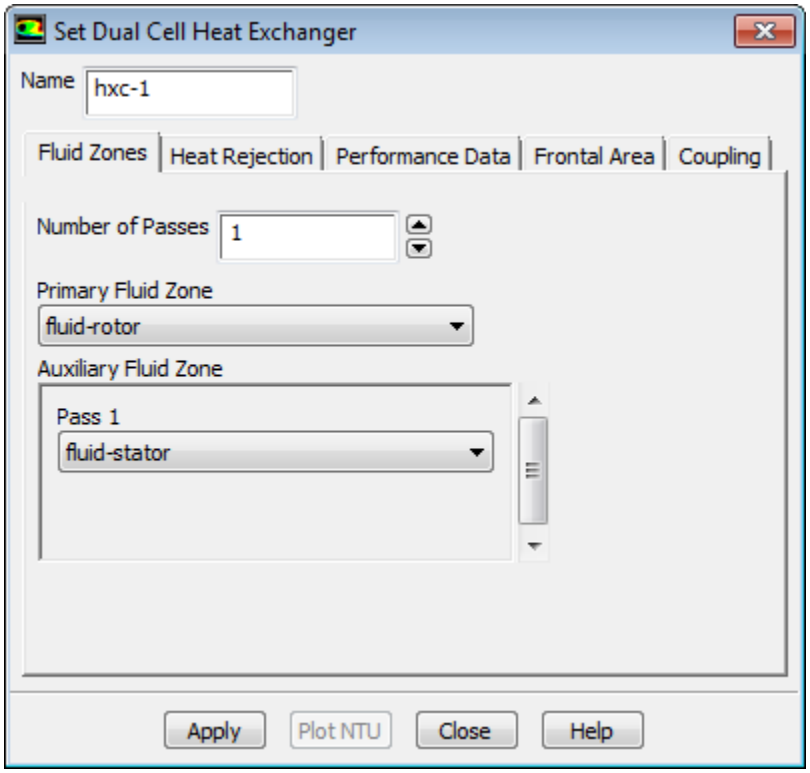
Delete
removes the currently selected heat exchanger.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modify...
opens the Set Dual Cell Heat Exchanger Dialog Box (p. 2202).

37.4.10. Set Dual Cell Heat Exchanger Dialog Box

The **Set Dual Cell Heat Exchanger** dialog box allows you to define the heat exchanger parameters. See Using the Dual Cell Heat Exchanger Model (p. 922) for details about using this dialog box.



Controls

Name
allows you to specify a name for the dual cell heat exchanger.

Fluid Zones
allows you to specify the fluid zone parameters for the heat exchanger.

Number of Passes
specifies the number of passes for the heat exchanger.

Primary Fluid Zone
allows you to specify the fluid of the primary fluid zone for the heat exchanger.

Auxiliary Fluid Zone
allows you to specify the fluid for the auxiliary fluid zone, per pass.

Important

The selected zones must be overlapping in physical space.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Heat Rejection
contains parameters specific to the rejection of heat in the heat exchanger.

Options
allows you to specify how the heat rejection in the heat exchanger is computed.

Fixed Heat Rejection
allows you to specify heat rejection parameters.

Fixed Inlet Temperature
allows you to use total heat rejection as the desired output.

Heat Rejection Targeted
allows you to specify the heat rejection desired from the heat exchanger (available only when the **Fixed Heat Rejection** option is enabled).

Inlet Zone for Temperature Updates
allows ANSYS Fluent to change the temperature of the specified inlet zone in order to match the targeted heat rejection (available only when the **Fixed Heat Rejection** option is enabled).

Temperature Update Under-Relaxation
controls convergence (available only when the **Fixed Heat Rejection** option is enabled).

Iteration Interval Between Temperature Updates
controls divergence (available only when the **Fixed Heat Rejection** option is enabled).

Performance Data
contains parameters for specifying the heat exchanger's performance data.

Options
allows you to choose between using raw performance data or NTU performance data.

Raw Data
allows you to specify raw performance data for the heat exchanger.

NTU Data
allows you to specify NTU performance data for the heat exchanger.

Heat Exchanger Performance Data
contains parameters concerning the heat exchanger's performance data.

NTU Table
opens the NTU Table Dialog Box (p. 2205) (available only when the **NTU Data** option is enabled).

Heat Transfer Table
opens the Heat Transfer Data Table Dialog Box (p. 2204) (available only when the **Raw Data** option is enabled).

Effectiveness-NTU Relation
computes the NTU values from the heat transfer data. Choose **cross-flow-unmixed**, **parallel-flow**, or **counter-flow**, all of which are described in NTU Relations (available only when the **Raw Data** option is enabled).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reference Inlet Temperature
allows you to specify the inlet reference temperature for the primary and the auxiliary fluids. (Available only when the **Raw Data** option is enabled.)

Frontal Area
allows you to specify the frontal area for the heat exchanger.

Primary Fluid
allows you to specify a value for the **Core Frontal Area** for the primary fluid, or to compute the value from a surface zone using the **Compute From** drop-down list.

Auxiliary Fluid
allows you to specify a value for the **Core Frontal Area** for the auxiliary fluid, or to compute the value from a surface zone using the **Compute From** drop-down list.

Coupling
specifies parameters when you want to couple the heat exchanger passes.

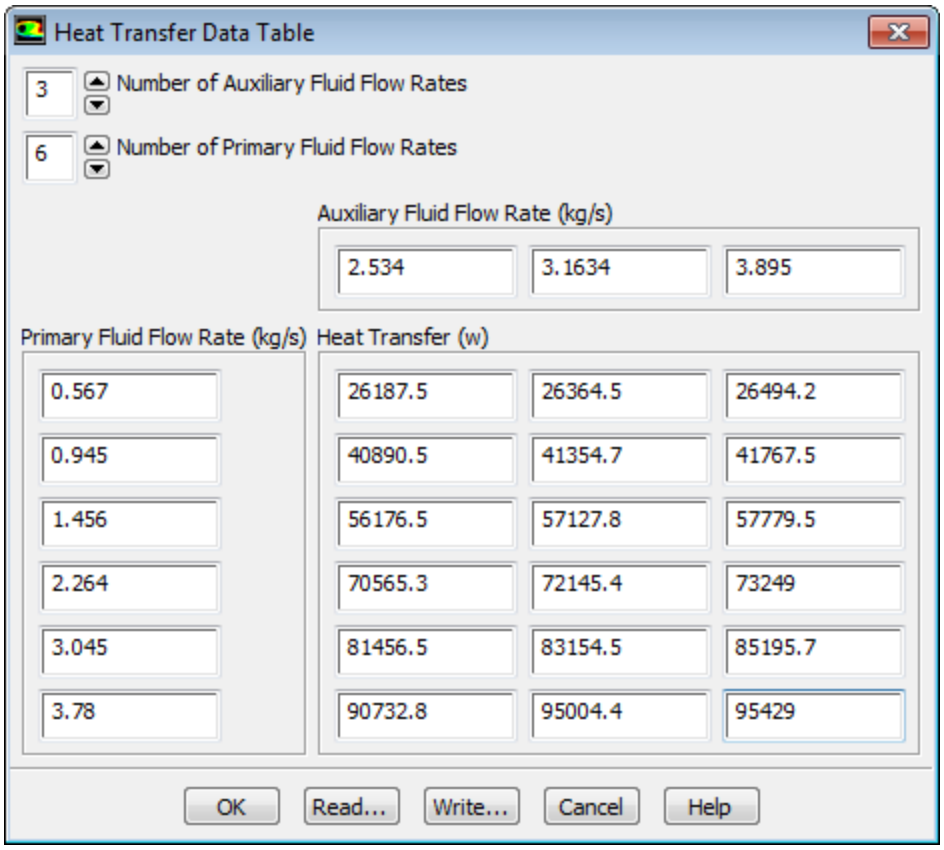
Temperature
specifies, by default, the mass-weighted average for the temperature of the outlet of Pass 1 to the inlet of Pass 2. Similarly, the mass-weighted-average temperature of the outlet of Pass 2 will be applied at the inlet zone of Pass 3, and so on. (Available only when multiple passes are specified in the **Fluid Zones** tab.)

Plot NTU
plots the performance data curve for the selected heat exchanger. The performance data is supplied through the **Performance Data** tab.

37.4.11. Heat Transfer Data Table Dialog Box

The **Heat Transfer Data Table** dialog box contains information on the number of fluid flow rates and heat transfer data for the primary and auxiliary fluids. See Using the Ungrouped Macro Heat Exchanger Model (p. 932) for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of Auxiliary Fluid Flow Rates
sets the number of auxiliary fluid flow rates.

Number of Primary Fluid Flow Rates
sets the number of primary fluid flow rates.

Auxiliary Fluid Flow Rate
sets fluid flow rates for the auxiliary fluid.

Primary Fluid Flow Rate
sets fluid flow rates for the primary fluid.

Heat Transfer
sets the heat transfer for the corresponding primary and auxiliary fluid flow rates.

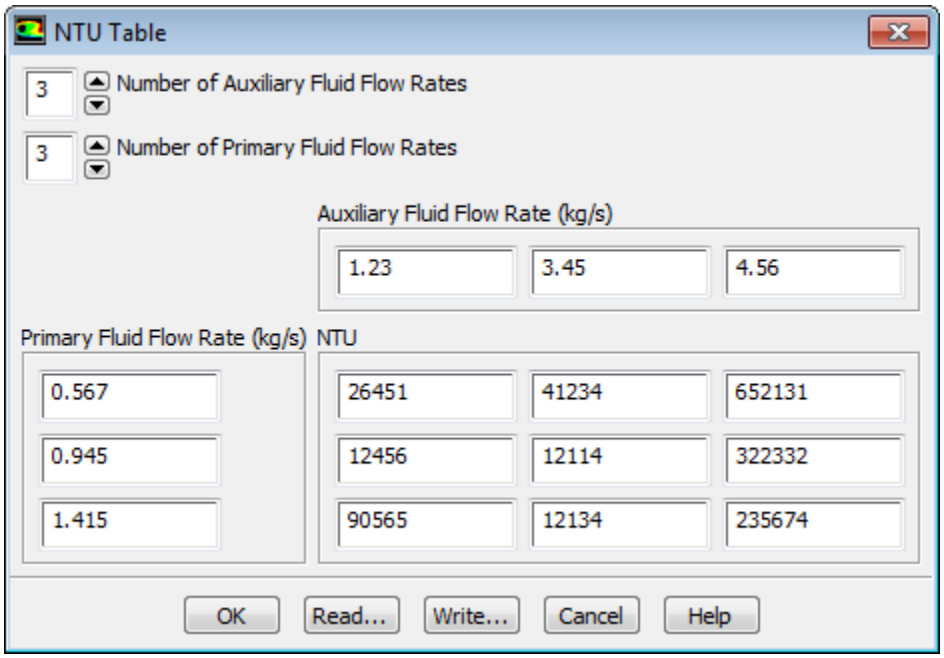
Read...
allows you to read in a file containing heat transfer data.

Write...
allows you to write a file containing heat transfer data.

37.4.12. NTU Table Dialog Box

The **NTU Table** dialog box contains information on the number of fluid flow rates and NTU data for the primary and auxiliary fluids. See Using the Ungrouped Macro Heat Exchanger Model (p. 932) for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of Auxiliary Fluid Flow Rates
sets the number of auxiliary fluid flow rates.

Number of Primary Fluid Flow Rates
sets the number of primary fluid flow rates.

Auxiliary Fluid Flow Rate
sets fluid flow rates for the auxiliary fluid.

Primary Fluid Flow Rate
sets fluid flow rates for the primary fluid.

NTU
sets the NTU values for the corresponding primary and auxiliary fluid flow rates.

Read...
allows you to read in a file containing NTU data.

Write...
allows you to write a file containing NTU data.

37.4.13. Copy From Dialog Box

The **Copy From** dialog box allows you to copy the setup of one heat exchanger to another.

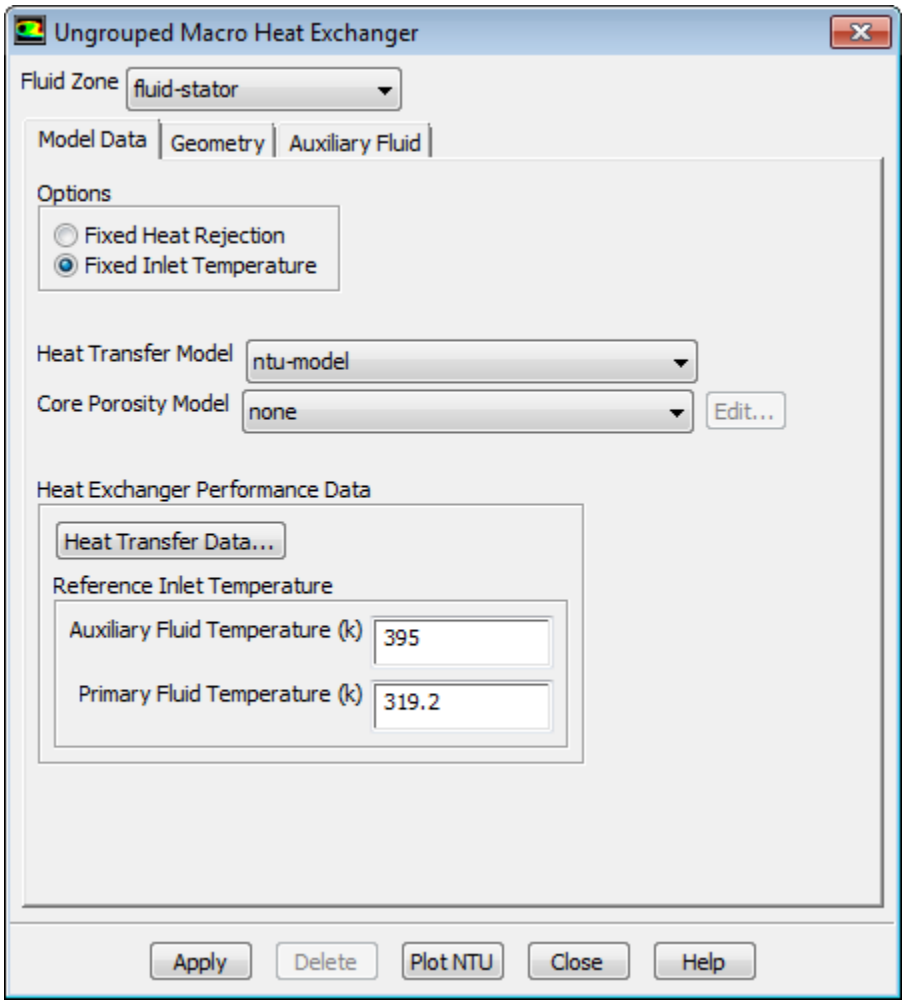
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Existing Heat Exchangers
contains a list of heat exchangers, from which you can copy the settings from one heat exchanger to another.

37.4.14. Ungrouped Macro Heat Exchanger Dialog Box

The **Ungrouped Macro Heat Exchanger** dialog box allows you to set up the ungrouped macro heat exchanger model. See Using the Ungrouped Macro Heat Exchanger Model (p. 932) for details about using this dialog box.



Controls

Fluid Zone
specifies the zone that represents the heat exchanger.

Model Data
contains the parameters related to the heat exchanger model.

Options
allows you to choose one of the following settings:

Fixed Heat Rejection
specifies that ANSYS Fluent should compute the auxiliary fluid inlet temperature for a specified heat rejection.

Fixed Inlet Temperature
specifies that ANSYS Fluent should compute the total heat rejection of the core for a given inlet auxiliary temperature.

Heat Transfer Model
allows you to specify either the **ntu-model** or the **simple-effectiveness-model** for heat transfer. See Choosing a Heat Exchanger Model (p. 920) for information on the differences between these models.

Core Porosity Model
contains a drop-down list of all available core porosity models.

Edit...
opens the Core Porosity Model Dialog Box (p. 2211).

Heat Exchanger Performance Data
contains the parameters for heat transfer.

Heat Transfer Data...
opens the Heat Transfer Data Table Dialog Box (p. 2204). This item will appear for the NTU model only.

Auxiliary Fluid Temperature
specifies the auxiliary fluid temperature. This item will appear only for the NTU model.

Primary Fluid Temperature
specifies the gas stream temperature. This item will appear only for the NTU model.

Velocity Effectiveness Curve...
opens the Velocity Effectiveness Curve Dialog Box (p. 2210) in which you can define the effectiveness of the heat exchanger core (ε in Equation 6.11 in the Theory Guide). This item will appear for simple effectiveness model only.

Geometry
contains parameters to define the macro grid.

Width
sets the width of the heat exchanger core. The **Width** is measured in the pass-to-pass direction.

Height
sets the height of the heat exchanger core. The **Height** is measured in the auxiliary fluid inlet direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Depth
sets the depth of the heat exchanger core.

Number of Passes
specifies the number of passes for the macro grid. (See Figure 13.17: 1x4x3 Macros (p. 939).)

Number of Rows/Pass, Number of Columns/Pass
specify the number of macro rows and columns per pass in the macro grid. (See Figure 13.17: 1x4x3 Macros (p. 939).)

View Passes
displays the macro grid. (This button becomes available after you click **Apply**.) The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n-1$ is blue.

Draw Mesh
toggles between displaying and not displaying the mesh when the macro mesh is displayed (using the **View Passes** button). The Mesh Display Dialog Box (p. 2163) opens when **Draw Mesh** is selected.

Update from Plane Tool
updates the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** from the plane tool orientation. The **Width**, **Height**, and **Depth** will also be updated. See Using the Plane Tool (p. 1724) for information about using the plane tool.

Auxiliary Fluid Inlet Direction (height)
specifies the direction in which the auxiliary fluid enters the heat exchanger. See Figure 13.17: 1x4x3 Macros (p. 939).

Pass-to-Pass Direction (width)
specifies the direction in which the auxiliary fluid moves at the end of each pass through the heat exchanger. See Figure 13.17: 1x4x3 Macros (p. 939).

Auxiliary Fluid
contains the option to specify the auxiliary fluid properties.

Auxiliary Fluid Properties Method
contains options for specifying auxiliary fluid properties.

constant-specific-heat
allows you to specific a constant value for the auxiliary fluid specific heat.

user-defined-enthalpy
allows you to specify a user-defined function for the auxiliary fluid enthalpy.

Auxiliary Fluid Specific Heat
specifies the value of $c_{p,auxiliary}$ in Equation 6.17 in the Theory Guide. This value is specified only if **constant-specific-heat** is selected.

Auxiliary Fluid Enthalpy UDF
allows you to specify a user-defined function for the auxiliary fluid enthalpy (see Equation 6.17 in the Theory Guide). This option is available only when **user-defined-enthalpy** is selected.

Auxiliary Fluid Flow Rate
sets the flow rate of the auxiliary fluid ($\dot{m}$ in Equation 6.16 in the Theory Guide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Heat Rejection
sets the total heat rejection (q_{total} in Equation 6.15 in the Theory Guide). This value is specified only if **Fixed Heat Rejection** is selected.

Initial Temperature
sets an initial guess for the inlet temperature (T_{in} in Equation 6.11 and Equation 6.16 in the Theory Guide). This value is specified only if **Fixed Heat Rejection** is selected.

Inlet Temperature
sets the auxiliary fluid initial temperature (T_{in} in Equation 6.11 and Equation 6.16 in the Theory Guide). This value is specified only if **Fixed Inlet Temperature** is selected in the **Model Data** tab.

Inlet Pressure
sets the auxiliary fluid inlet pressure. This value is specified only if **user-defined-enthalpy** is selected.

Inlet Quality
specifies the value of x in Equation 6.20 in the Theory Guide. This value is specified only if **user-defined-enthalpy** is selected.

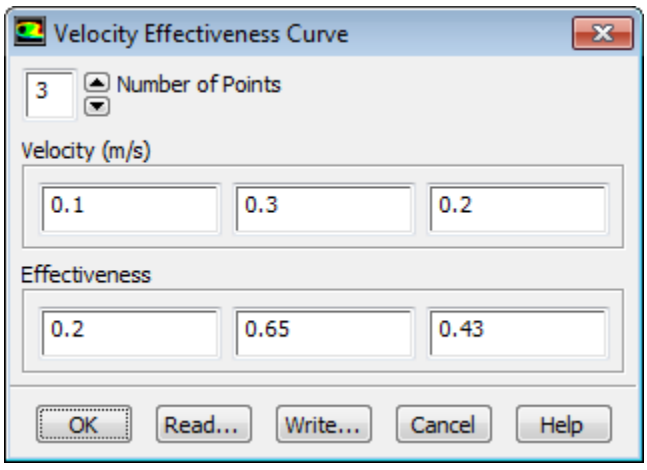
Pressure Drop
specifies the value of p_{in} in Equation 6.21 in the Theory Guide. This value is specified only if **user-defined-enthalpy** is selected.

Apply
saves all the settings for the heat exchanger specified in the **Fluid Zone** list.

Delete
deletes the heat exchanger specified in the **Fluid Zone** list.

37.4.15. Velocity Effectiveness Curve Dialog Box

The **Velocity Effectiveness Curve** dialog box allows you to define effectiveness curve. It is opened by clicking **Velocity Effectiveness Curve...** in the Ungrouped Macro Heat Exchanger Dialog Box (p. 2207).



Controls

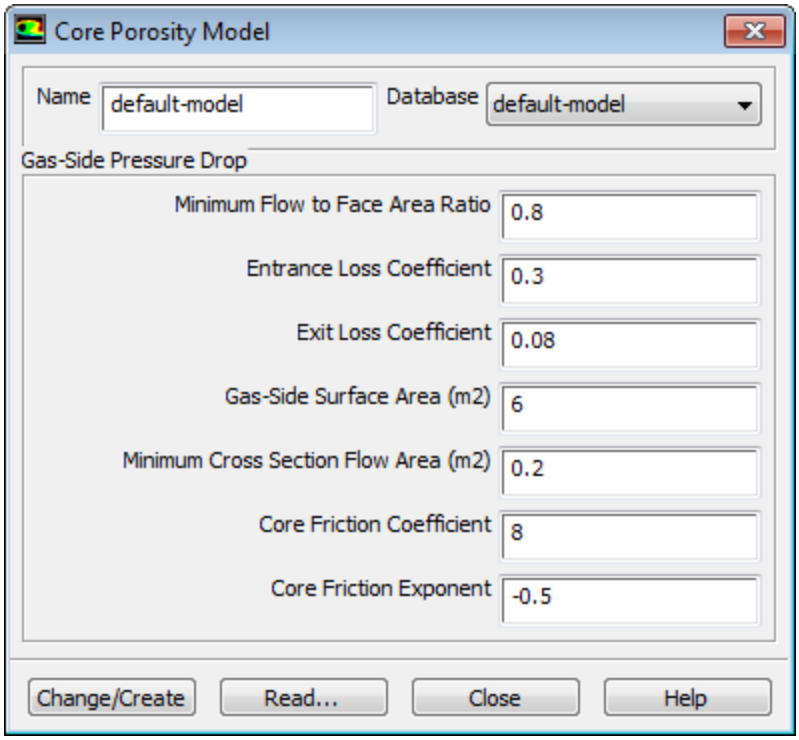
Number of Points
specifies the number of data pairs in the effectiveness profile. The default value of 1 indicates a constant effectiveness.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Velocity, Effectiveness
specify the data pairs for the effectiveness profile. These items are available only if the simple effective model has been selected. Note that the **Effectiveness** values must be within the range of 0–1.

37.4.16. Core Porosity Model Dialog Box

The **Core Porosity Model** dialog box allows you to modify or define a heat exchanger core model. This dialog box opens when you click **Edit...** in the Ungrouped Macro Heat Exchanger Dialog Box (p. 2207).



Controls

Name
specifies the name of a new heat exchanger core model.

Database
contains a drop-down list of all heat exchanger core models that are currently available.

Gas-Side Pressure Drop
contains parameters that define the air-side pressure drop.

Minimum Flow to Face Area Ratio
sets the value of σ in Equation 6.2 in the Theory Guide.

Entrance Loss Coefficient
sets the value of K_c in Equation 6.2 in the Theory Guide.

Exit Loss Coefficient
sets the value of K_e in Equation 6.2 in the Theory Guide.

Gas Side Surface Area
sets the value of A in Equation 6.2 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Minimum Cross Section Flow Area
sets the value of A_c in Equation 6.2 in the Theory Guide.

Core Friction Coefficient
sets the value of a in Equation 6.3 in the Theory Guide.

Core Friction Exponent
sets the value of b in Equation 6.3 in the Theory Guide.

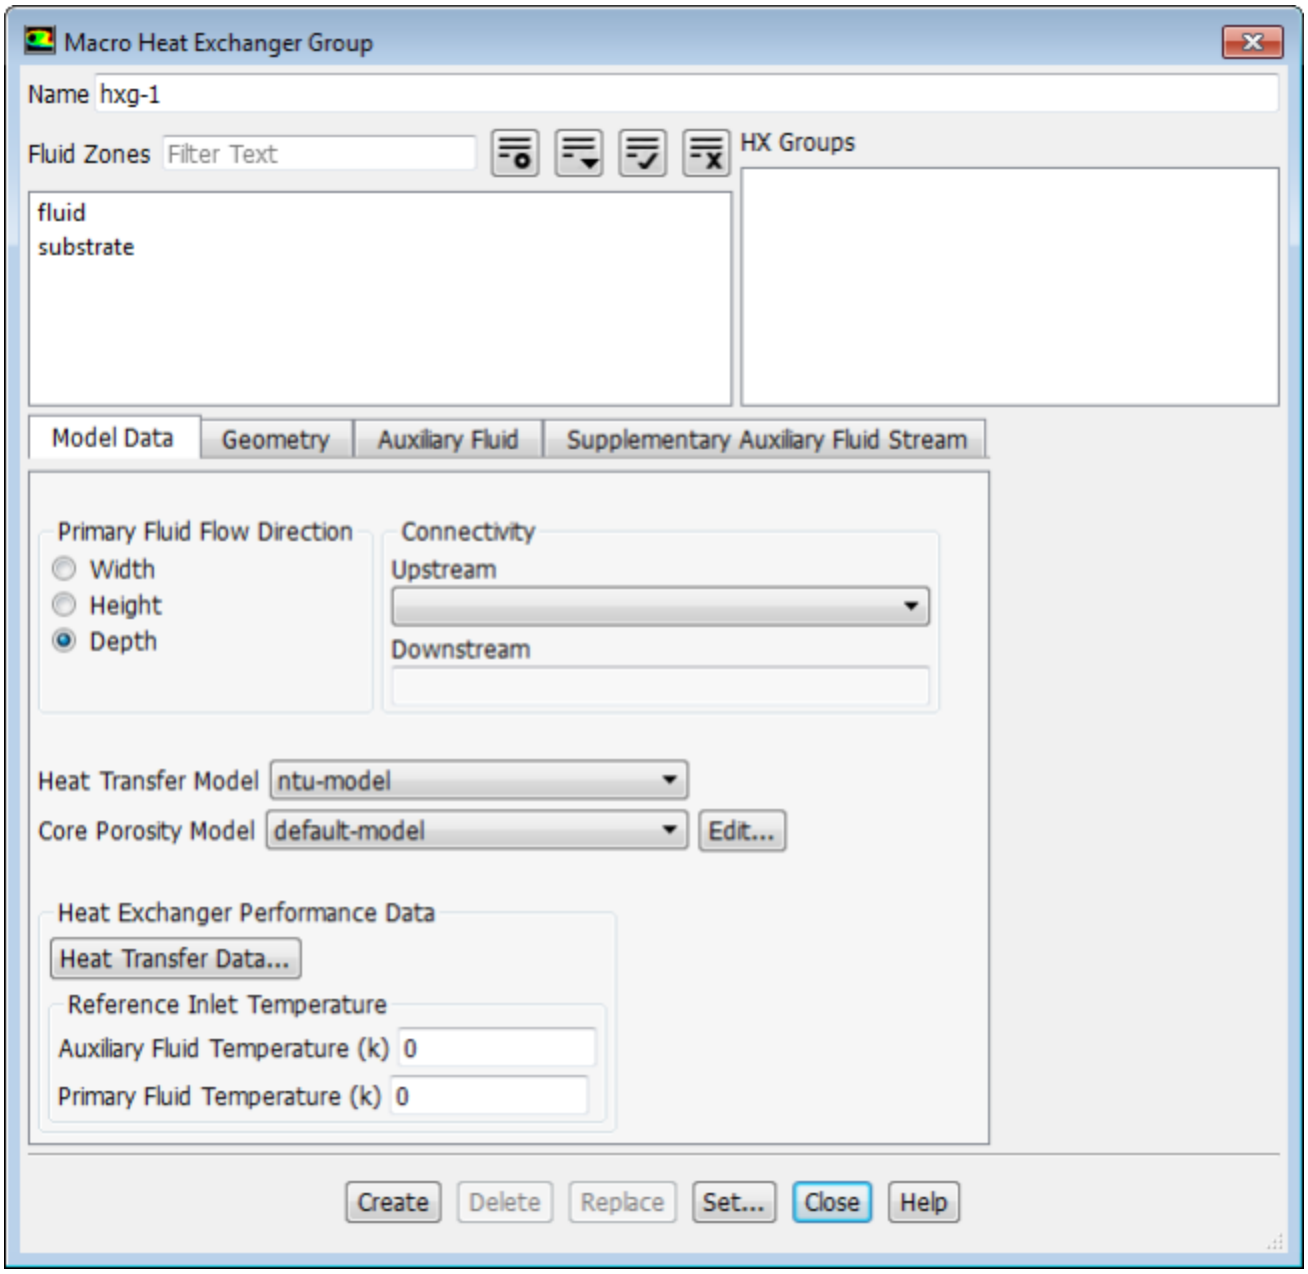
Change/Create
saves the settings in the dialog box and adds the new model to the **Database** list.

Read...
opens The Select File Dialog Box (p. 19), in which you can select an external file containing a predefined heat exchanger core model.

37.4.17. Macro Heat Exchanger Group Dialog Box

The **Macro Heat Exchanger Group** dialog box allows you to modify or define a heat exchanger core group.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
specifies the name of a new heat exchanger group.

Fluid Zones
contains a list of all the fluid zones.

HX Groups
contains list of the heat exchanger groups.

Model Data
contains all the parameters to be specified for the model.

Primary Fluid Flow Direction
gives you a choice of gas flow direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Width, Height, Depth
specifies the width, height and the depth of the gas flow direction.

Connectivity
allows you to define the upstream and downstream connections.

Upstream
specifies the upstream heat exchanger group.

Downstream
specifies the downstream heat exchanger group.

Heat Transfer Model
allows you to select either the **simple-effectiveness-model** or the **ntu-model**. See Choosing a Heat Exchanger Model (p. 920) for information on the differences between these models.

Core Porosity Model
specifies whether default values are chosen for the core porosity model.

Edit...
opens the Core Porosity Model Dialog Box (p. 2211) for the definition of a new core porosity model.

Heat Exchanger Performance Data
contains the parameters for heat transfer.

Heat Transfer Data...
opens the Heat Transfer Data Table Dialog Box (p. 2204). This dialog box allows you to define the heat transfer for different primary and auxiliary fluid flow rates. This item will appear for the NTU model only.

Velocity Effectiveness Curve...
opens the Velocity Effectiveness Curve Dialog Box (p. 2210) in which you can define the effectiveness of the heat exchanger core (ε in Equation 6.11 in the Theory Guide). This item will appear for simple effectiveness model only.

Auxiliary Fluid Temperature
specifies the auxiliary fluid temperature. This item will appear for the NTU model only.

Primary Fluid Temperature
specifies the gas stream fluid temperature. This item will appear for the NTU model only.

Geometry
contains parameters to define the macro grid.

Width, Height, Depth
specifies the width, height and the depth of the heat exchanger.

Number of Passes
specifies the number of passes.

Number of Rows/Pass
specifies the number of rows per pass.

Number of Columns/Pass
specifies the number of columns per pass.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

View Passes
displays the macro grid. (This button becomes available after you click **Set**.) The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n-1$ is blue.

Draw Mesh
toggles between displaying and not displaying the mesh when the macro mesh is displayed (using the **View Passes** button). The Mesh Display Dialog Box (p. 2163) opens when **Draw Mesh** is selected.

Update from Plane Tool
updates the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** from the plane tool orientation. The **Width**, **Height**, and **Depth** will also be updated. See Using the Plane Tool (p. 1724) for information about using the plane tool.

Auxiliary Fluid Inlet Direction
specifies the direction in which the auxiliary fluid enters the heat exchanger. See Figure 13.17: 1x4x3 Macros (p. 939).

Pass-to-Pass Direction
specifies the direction in which the auxiliary fluid moves at the end of each pass through the heat exchanger. See Figure 13.17: 1x4x3 Macros (p. 939).

Auxiliary Fluid
contains inputs to specify the properties of the auxiliary fluid.

Properties Method
specifies the method to specify the auxiliary fluid properties. You can choose from **constant-specific-heat** and **user-defined-enthalpy**.

Specific Heat
sets the specific heat of the auxiliary fluid (c_p in Equation 6.16 you choose **constant-specific-heat**.

Enthalpy UDF
sets the enthalpy as defined by the user-defined function selected from the drop-down list.

Auxiliary Fluid Flow Rate
sets the flow rate of the auxiliary fluid ($\dot{m}$ in Equation 6.16 in the Theory Guide).

Initial Temperature
sets an initial guess for the inlet temperature (T_{in} in Equation 6.11 and Equation 6.16 in the Theory Guide). This value is specified only if **Fixed Heat Rejection** is selected.

Inlet Pressure
sets the auxiliary fluid inlet pressure. This value is specified only if **user-defined-enthalpy** is selected.

Inlet Quality
specifies the value of x in Equation 6.20 in the Theory Guide.

Pressure Drop
specifies the value of p_{in} in Equation 6.21 in the Theory Guide. This value is specified only if **user-defined-enthalpy** is selected.

Supplementary Auxiliary Fluid Stream
specifies properties of the supplementary auxiliary stream.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Supplementary Mass Flow Rate
specifies the supplementary fluid flow rate as **constant**, **polynomial** or **piecewise-linear**.

Supplementary Flow Temperature
specifies the supplementary fluid temperature as **constant**, **polynomial** or **piecewise-linear**.

Supplementary Flow Quality
specifies the supplementary fluid quality.

Create
saves all the settings in the dialog box.

Delete
deletes the group that is selected in the **HX Groups** list.

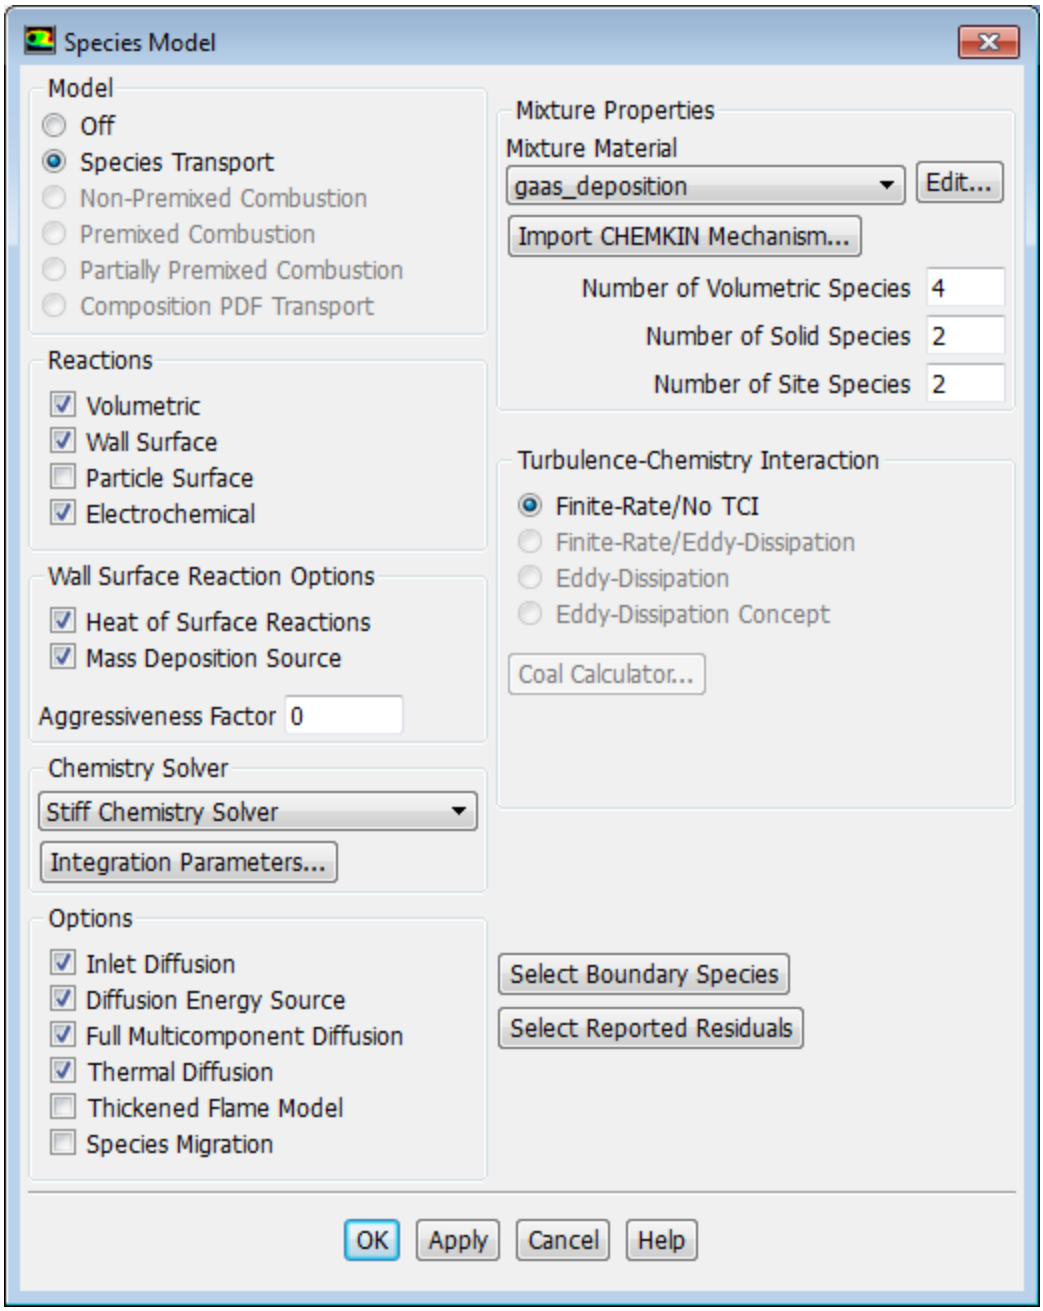
Replace
changes the parameters of the already existing group that is selected in the **HX Groups** list.

Set...
opens the Ungrouped Macro Heat Exchanger Dialog Box (p. 2207), in which you can define a new heat exchanger core model or read one from an external file.

37.4.18. Species Model Dialog Box

The **Species Model** dialog box allows you to set parameters related to the calculation of species transport and combustion. See Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960), Manual Inputs for Wall Surface Reactions (p. 998), User Inputs for Particle Surface Reactions (p. 1001), Using the Premixed Combustion Model (p. 1090), Using the Partially Premixed Combustion Model (p. 1100), and Steps for Using the Composition PDF Transport Model (p. 1113) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

indicates which model, if any, is used to calculate species transport/combustion.

Off

disables species calculations.

Species Transport

enables the calculation of multi-species transport (either non-reacting or reacting, depending on the selection for **Reactions**). See Modeling Species Transport and Finite-Rate Chemistry (p. 957) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Non-Premixed Combustion
enables the calculation of turbulent reacting flow using the non-premixed combustion model. See Modeling Non-Premixed Combustion (p. 1025) for details. This option is available only for turbulent flows using the pressure-based solver.

Premixed Combustion
enables the premixed turbulent combustion model. See Modeling Premixed Combustion (p. 1089) for details. This option is available only for turbulent flows using the pressure-based solver.

Partially Premixed Combustion
enables the partially premixed turbulent combustion model. See Modeling Partially Premixed Combustion (p. 1099) for details. This option is available only for turbulent flows using the pressure-based solver.

Composition PDF Transport
enables the composition PDF transport model. See Modeling a Composition PDF Transport Problem (p. 1113) for details. This option is available only for turbulent flows using the pressure-based solver.

Reactions
contains options related to the modeling of reacting flow. (This section of the dialog box appears only when **Species Transport** or **Composition PDF Transport** is the specified **Model**.)

Volumetric
enables the calculation of reacting flow using the finite-rate formulation. See Volumetric Reactions (p. 958) for details.

Wall Surface
enables the calculation of wall surface reactions. See Wall Surface Reactions and Chemical Vapor Deposition (p. 995) for details. This item will appear only if **Volumetric** is enabled.

Particle Surface
enables the calculation of particle surface reactions. See Particle Surface Reactions (p. 1001) for details. This item will appear only if **Volumetric** is enabled.

Electrochemical
enables the calculation of electrochemical reactions. See Electrochemical Reactions (p. 1003) for details. This item will appear only if **Volumetric** is enabled.

Integration Parameters...
is a command button that opens the Integration Parameters Dialog Box (p. 2235). This button appears for the species transport model, when **Volumetric** is enabled under **Reactions** and **Stiff Chemistry Solver** is enabled under **Options** or when **Eddy-Dissipation Concept** is enabled under **Turbulence-Chemistry Interaction**.

Wall Surface Reaction Options
contains additional options for wall surface reactions. This portion of the dialog box appears only if **Wall Surface** is enabled under **Reactions**.

Heat of Surface Reactions
(if enabled) includes the heat release due to surface reactions in the energy equation. You must remember to set appropriate formation enthalpies (standard state enthalpies) if you enable this option.

Mass Deposition Source
(if enabled) includes the effect of surface mass transfer in the continuity equation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Aggressiveness Factor
is a numerical factor that controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5.

Chemistry Solver
is a drop-down list in which you can select the solver for the chemically reactive flow simulation. This item appears only for **Species Transport** and **Composition PDF Transport** models involving **Volumetric** reactions.

Stiff Chemistry Solver
enables efficient integration of stiff chemical kinetics. This item appears only when **Finite-Rate/No TCI** or **Eddy-Dissipation Concept** is selected in the **Turbulence-Chemistry Interaction** group box. See Solution of Stiff Chemistry Systems (p. 992) for details.

CHEMKIN-CFD Solver
enables the integration of chemical kinetics using the ANSYS CHEMKIN-CFD Solver, designed for large, stiff chemistry mechanisms. This item appears only when **Finite-Rate/No TCI** or **Eddy-Dissipation Concept** is selected in the **Turbulence-Chemistry Interaction** group box.

Relax to Chemical Equilibrium
enables efficient modeling of chemical kinetics effects based only on equilibrium calculation and assumptions about characteristic timescales for approaching equilibrium. This item is not available for the **Eddy Dissipation Concept TCI** option. (See The Relaxation to Chemical Equilibrium Model for details.

None - Explicit Source
makes explicit use of chemistry source terms in the species transport equations, without a stiff-chemistry solver (not recommended for stiff or complex chemistry).

Options
contains additional options for the **Species Transport** model and for the **Composition PDF Transport**. (This section will not appear in the dialog box for the other models.)

Inlet Diffusion
includes the diffusion flux of species at inlet.

Diffusion Energy Source
(if enabled) includes the effect of enthalpy transport due to species diffusion in the energy equation.

Full Multicomponent Diffusion
enables the full multicomponent diffusion model. See Full Multicomponent Diffusion (p. 520) for details.

Thermal Diffusion
enables the thermal diffusion model. See Thermal Diffusion Coefficients (p. 522) for details.

Liquid Micro-Mixing
is used to model liquid reactions. When the **Liquid Micro-Mixing** model is invoked, ANSYS Fluent uses the **volume-weighted-mixing-law** formula to calculate the density.

Species Migration
(if enabled) includes the ion species migration term in the species transport equation. This item appears only when **Electrochemical** reactions are enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thickened Flame Model
enables the modeling of laminar flames. This application is typically used as an LES combustion model for turbulent premixed and partially-premixed flames.

Include Temperature Fluctuations
enables the calculation of the multi-mode energy equation. This option is available when the composition PDF transport model is selected.

Mixture Properties
contains controls and information about the mixture being modeled. This section of the dialog box will not appear if **Premixed Combustion** is the selected under **Model**.

Mixture Material
contains a drop-down list of available mixture materials. When you first enable the **Species Transport** model, you can choose from all of the mixture materials defined in the database, or you can choose a "template" and define your own material. (Click **View...** to open the Fluent Database Materials Dialog Box (p. 2312) and check the properties of the mixture material selected in the list.) See Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960) for details.

When you use the **Non-Premixed Combustion** or **Partially Premixed Combustion** model, this list will be inactive. The mixture material for a non-premixed or partially premixed combustion calculation will be determined from the content of the PDF file generated in ANSYS Fluent using the **PDF Options** parameters.

Number of Volumetric Species
displays the number of gas-phase species in the selected **Mixture Material**. This is an informational display only; you cannot edit this value.

Number of Solid Species
displays the number of solid species defined in the selected **Mixture Material**. This is an informational display only; you cannot edit this value. (This list will appear only for **Species Transport** models involving **Wall Surface** reactions.)

Number of Site Species
displays the number of site species defined in the selected **Mixture Material**. This is an informational display only; you cannot edit this value. (This list will appear only for **Species Transport** models involving **Wall Surface** reactions.)

Turbulence-Chemistry Interaction
indicates which model is to be used for turbulence-chemistry interaction when the **Species Transport** model with **Volumetric** reactions is used.

Laminar Finite-Rate
computes only the Arrhenius rate (see Equation 7.7 in the Theory Guide) and neglects turbulence-chemistry interaction.

Finite-Rate/Eddy-Dissipation
(for turbulent flows) computes both the Arrhenius rate and the mixing rate and uses the smaller of the two.

Eddy-Dissipation
(for turbulent flows) computes only the mixing rate (see Equation 7.25 and Equation 7.26 in the Theory Guide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eddy-Dissipation Concept
(for turbulent flows) models turbulence-chemistry interaction with detailed chemical mechanisms (see Equation 7.25 and Equation 7.26 in the Theory Guide).

Coal Calculator...
opens the Coal Calculator Dialog Box (p. 2232).

Select Boundary Species...
opens the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)).

Select Reported Residuals
opens the **Select Residual Monitored Species** dialog box (see Figure 14.4: The Select Residual Monitored Species (p. 967)).

Options
contains parameters related to the Laminar Finite-Rate or the Eddy-Dissipation Concept model. This section of the dialog box will appear when **Laminar Finite-Rate** or the **Eddy-Dissipation Concept** is selected for **Turbulence-Chemistry Interaction**.

Flow Iterations Per Chemistry Update
specifies how often ANSYS Fluent will update the chemistry during the calculation. Increasing the number can reduce the computational expense of the chemistry calculations.

Aggressiveness Factor
is a numerical factor that controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5.

Volume Fraction Constant
specifies the value of C_{ξ} in Equation 7.28 in the Theory Guide.

Time Scale Constant
specifies the value of C_{τ} in Equation 7.29 in the Theory Guide.

Number of Grid Points in Flame
by default are 8 grid points.

PDF Options
contains options related for the non-premixed combustion model. (This section will appear only if **Non-Premixed Combustion** or **Partially-Premixed Combustion** is the selected **Model**.)

Inlet Diffusion
includes the diffusion flux of species at inlet.

Compressibility Effects
can be enabled to account for cases where substantial pressure changes occur in time and/or space when modeling a non-adiabatic system. See Specifying the Operating Pressure for the System (p. 1033) for details.

Liquid Micro-Mixing
is used to model liquid reactions. When the **Liquid Micro-Mixing** model is invoked, ANSYS Fluent uses the **volume-weighted-mixing-law** formula to calculate the density.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chemistry
tab contains the parameters to define problems using the chemistry model. See Setting Up the Equilibrium Chemistry Model (p. 1031) for details.

State Relation

Chemical Equilibrium
enables the equilibrium chemistry model. See Setting Up the Equilibrium Chemistry Model (p. 1031) for details.

Steady Diffusion Flamelet
enables the steady diffusion flamelet model. See The Diffusion Flamelet Models Theory in the Theory Guide for details.

Unsteady Diffusion Flamelet
enables the Eulerian unsteady diffusion flamelet model.

Diesel Unsteady Flamelet
enables the diesel unsteady laminar flamelet model. See Using the Diesel Unsteady Laminar Flamelet Model (p. 1038) for details.

Flamelet Generated Manifold
enables the flamelet generated manifold (FGM) model. This is available when the **Partially Premixed Combustion** model is selected. See Partially Premixed Combustion in the Theory Guide for details.

Energy Treatment

Adiabatic
enables adiabatic modeling options for the problem.

Non-Adiabatic
enables non-adiabatic modeling options for the problem. See Non-Adiabatic Extensions of the Non-Premixed Model in the Theory Guide for details.

Coal Calculator
opens the Coal Calculator Dialog Box (p. 2232).

Stream Options
contains the parameters for the equilibrium chemistry model or the steady diffusion flamelet model.

Secondary Stream
includes the secondary inlet stream in the model.

Empirical Fuel Stream
enables parameters to define fuel stream empirically. This option is available only with the full equilibrium chemistry model.

Empirical Secondary Stream
enables parameters to define secondary stream empirically. This option is available only with the full equilibrium chemistry model.

Model Settings
contains a list of parameter settings.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Operating Pressure
specifies the system operating pressure used to calculate the density using the ideal gas law. See Specifying the Operating Pressure for the System (p. 1033) for details.

Fuel Stream Rich Flamability Limit
specifies the rich flammability limit for fuel stream when the equilibrium chemistry option is used. You will not set these if you have used the empirical definition option for fuel composition. See Enabling the Rich Flammability Limit (RFL) Option (p. 1035) for details.

Secondary Stream Flamability Limit
specifies the rich flammability limit for secondary stream when the equilibrium chemistry option is used. You will not set these if you have used the empirical definition option for fuel composition. See Enabling the Rich Flammability Limit (RFL) Option (p. 1035) for details.

Empirical Fuel Lower Calorific Value
specifies the lower calorific value of fuel stream.

Empirical Fuel Specific Heat
specifies the specific heat value of fuel stream.

Empirical Fuel Molecular Weight
specifies the molecular weight of the fuel stream.

Empirical Secondary Lower Calorific Value
specifies the lower calorific value of secondary stream.

Empirical Secondary Specific Heat
specifies the specific heat value of secondary stream.

Empirical Secondary Molecular Weight
specifies the molecular weight of the secondary stream.

Options
contains options related to the steady flamelet model.

Create Flamelet
enables the **Import CHEMKIN Mechanism...** button that opens the CHEMKIN Mechanism Import Dialog Box (p. 2642) where you can import the CHEMKIN mechanism and thermodynamic data, to create a flamelet file. This option is available for the steady flamelet model. See Setting Up the Steady and Unsteady Diffusion Flamelet Models (p. 1036) for details.

Import Flamelet
enables the **Import Flamelet File...** button that opens The Select File Dialog Box (p. 19) where you can select the existing flamelet in ANSYS Fluent. You can also set the file type parameters to import the existing flamelet in ANSYS Fluent. See Setting Up the Steady and Unsteady Diffusion Flamelet Models (p. 1036) for details. This option is available for the steady flamelet model.

Flamelet Type
gives you the option of creating a **Premixed Flamelet** or a **Diffusion Flamelet**. This is available when the **Flamelet Generated Manifold** model is selected.

File Type
contains the toggle buttons for two flamelet file types.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Standard
enables the import of an ASCII format standard flamelet file.

CFX-RIF
enables the import of an ASCII format CFX-RIF flamelet file.

Flamelet Property File Name
opens The Select File Dialog Box (p. 19) in which you can save the existing flamelet in ANSYS Fluent to use when running an existing case.

Thermodynamic Database File Name
specifies a path for the thermodynamic database file to be read.

Boundary
tab contains the list of boundary species and related parameters. This is available only for equilibrium chemistry model. See Defining the Stream Compositions (p. 1042) for details.

Species
contains the list of the species used in the problem.

Fuel
specifies the fuel species.

Oxid
specifies the oxidizing species.

Second
specifies the secondary species.

Boundary Species
allows you to specify the species you want to add or remove from the model. You can type the species chemical formula in the field below it.

Add
adds the species in the model.

Remove
removes the species from the model.

List Available Species
prints a list of all species in the thermodynamic database file (`thermo.db`) in the console window.

Temperature
specifies the temperature of different streams that you have defined.

Fuel
is the temperature of the fuel inlet in the model.

Oxid
is the temperature of the oxidizer inlet in the model.

Second
is the temperature of the secondary stream inlet in the model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specify Species in
allows you to define the unit of species concentration.

Mass Fraction
allows you to specify the species in terms of mass fraction.

Mole Fraction
allows you to specify the species in terms of mole fraction.

Control
tab contains the parameters for exclusion and inclusion of equilibrium species. This is available only for equilibrium chemistry model. See Forcing the Exclusion and Inclusion of Equilibrium Species (p. 1053) for details.

Species Excluded from Equilibrium
lists the species excluded from equilibrium calculation.

Species
lists the slow-forming species that are zeroed in the initial flamelet profile.

Add
allows you to add equilibrium species.

Remove
allows you to remove equilibrium species.

List Available Species
prints a list of all species in the thermodynamic database file in the console window.

Flamelet Controls
allows you to adjust the controls for the flamelet solution. Note that the **Create Flamelet** option in the **Chemistry** tab must be selected for the **Steady Diffusion Flamelet** or **Flamelet Generated Manifold** models for these controls to be available.

Initial Fourier Number
sets the first time step for the solution.

Fourier Number Multiplier
increases the time step at subsequent times. Every time step after the first is multiplied by this value.

Relative Error Tolerance and Absolute Error Tolerance
specifies the local error controls during numerical integration.

Flamelet Convergence Tolerance
specifies the maximum absolute change in species fraction or temperature at any discrete mixture-fraction.

Maximum Integration Time
specifies the maximum total elapsed time for flamelet calculation. ANSYS Fluent will stop the flamelet calculation after the total elapsed time has exceeded this value.

Flamelet
tab allows you to adjust the controls for the flamelet solution. See Defining the Flamelet Controls (p. 1054) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Flamelet Parameters

consist of the controls for the flamelet solution.

> **Note**
>
> The parameters may vary slightly if you selected the **Flamelet Generated Manifold** model (see Flamelet Generated Manifold (p. 1103) for those specific parameters).

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f=0$) and the fuel ($f=1$).

Maximum Number of Flamelets

specifies the maximum number of laminar flamelet profiles to be calculated.

Initial Scalar Dissipation

is the scalar dissipation of the first flamelet in the library.

Scalar Dissipation Step

specifies the interval between scalar dissipation values (in s^{-1}) for which multiple flamelets will be calculated.

User Defined Flamelet Parameters

enables you to hook a user-defined function for scalar dissipation and mean mixture fraction (or progress variable) grid discretization

Include Equilibrium Flamelet

determines whether the equilibrium assumption is used to compute the progress variable (Equation 9.2 in the *Fluent Theory Guide*). By default, this option is selected. If you turn off this option, ANSYS Fluent will compute the progress variable using the solution of flamelet generated with initial scalar dissipation as a denominator in Equation 9.2 in the *Fluent Theory Guide*.

Unsteady Flamelet Parameters

consist of the controls for the unsteady flamelet solution.

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f=0$) and the fuel ($f=1$).

Mixture Fraction Lower Limit for Initial Probability

is the limit at which the unsteady flamelet model temporally convects and diffuses a marker probability equation through a steady-state ANSYS Fluent flow-field.

Maximum Scalar Dissipation

is where flamelets extinguish at large scalar dissipation (mixing) rates.

Courant Number

is the number at which ANSYS Fluent automatically selects the time step for the probability equation based on this convective Courant number.

Number of Flamelets

specifies the number of unsteady laminar flamelets that ANSYS Fluent will automatically generate during the simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Calculate Flamelets
begins the laminar flamelet calculation.

Display Flamelets...
opens the Flamelet 3D Surfaces Dialog Box (p. 2237) from which you can display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation.

Initialize Unsteady Flamelet Probability
initializes the unsteady flamelet and its probability marker equation.

Display Unsteady Flamelet...
opens the Flamelet 2D Curves Dialog Box (p. 2239) from which you can display 2D plots of the different variables.

Table
tab contains parameters to create the look-up table. See Calculating the Look-Up Tables (p. 1063) for details of the items listed below.

Note

If you selected the **Flamelet Generated Manifold** model, the parameters will be different. See Calculating the Look-Up Tables (p. 1105) for those specific parameters.

Table Parameters
consists of the controls for the lookup table. A different set of parameters for you to enter will be displayed if **Automated Grid Refinement** is enabled or disabled.

Initial Number of Grid Points
specifies the number of grid points for the resolution of the mean mixture fraction, mixture fraction variance, and mean enthalpy (for non-adiabatic systems).

Maximum Number of Grid Points
specifies the maximum number of grid points used for tabulation. The grid refinement procedure will stop inserting the points when either the change in value and slope between successive points is within tolerance or the maximum number of grid points are generated.

Maximum Change in Value Ratio
specifies the maximum allowable change in value of table variables between successive grid points as specified by Equation 8.27 in the Theory Guide.

Maximum Change in Slope Ratio
specifies the maximum change in the slope of table variables between successive grid points as specified by Equation 8.28 in the Theory Guide.

Maximum Number of Species
is the maximum number of species stored in the lookup tables.

Minimum Temperature
specifies the minimum temperature in the lookup tables.

Number of Mean Mixture Fraction Points
is the number of discrete values of $\overline{f}$ at which the look-up tables will be computed.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Number of Secondary Mixture Fraction Points
is the number of discrete values of p_{sec} at which the look-up tables will be computed. This option is available only when a secondary stream has been defined.

Number of Mixture Fraction Variance Points
is the number of discrete values of $\overline{f'^2}$ at which the look-up tables will be computed. This option is available only when no secondary stream has been defined.

Maximum Number of Species
is the maximum number of species that will be included in the look-up tables.

Number of Mean Enthalpy Points
is the number of discrete values of enthalpy at which the three-dimensional look-up tables will be computed. This input is required only if you are modeling a non-adiabatic system.

Minimum Temperature
is used to determine the lowest temperature for which the look-up tables are generated (see Figure 8.10: Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems in the Theory Guide). This option is available only if you are modeling a non-adiabatic system.

Automated Grid Refinement
is an adaptive algorithm that inserts grid points in all table dimensions so that changes in the values of tabulated variables (such as mean temperature, density and species mass fractions) between successive grid points, as well as changes in their slopes, are less than a user specified tolerance.

Include Equilibrium Flamelet
specifies that an equilibrium flamelet (that is, $\chi=0$) will be generated in ANSYS Fluent and appended to the flamelet library before the PDF table is calculated. This option is available only when you are generating more than one laminar flamelet.

Calculate PDF Table
generates the look-up table.

Display PDF Table
opens the PDF Table Dialog Box (p. 2240) where you can display 2D plots and 3D surfaces showing the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy.

Properties
tab contains parameters needed to modify the piecewise-linear points. See Modifying the Unburnt Mixture Property Polynomials (p. 1110) for the details.

Partially Premixed Mixture Properties
contains the list of properties that you can modify. **Edit...** opens the **Quadratic Mixture Fraction** dialog box where you can modify the values of the polynomial coefficients.

For each polynomial function of $\overline{f}$ under **Partially Premixed Mixture Properties** you can click **Edit...** and specify values for **Coefficient 1**, **Coefficient 2**, **Coefficient 3**, and **Coefficient 4** in the appropriate **Quadratic of Mixture Fraction** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Non-Adiabatic Laminar Flame Speed
when enabled includes the non-adiabatic effects on the laminar flame speed by tabulating the laminar speeds in the PDF table. See Laminar Flame Speed in the Theory Guide.

Recalculate Properties
will calculate the partially premixed properties.

Premix
tab contains the options and the parameters for the **Turbulent Flame Speed Model**, the **Variance Settings**, and the **Turbulence-Chemistry Interaction**.

Turbulent Flame Speed Model
contains the **Flame Speed Model** drop-down list, which allows you to choose between the **zimont** or the **peters** model constants for the Zimont premixed combustion model. (This section will appear only if **Premixed Combustion** or **Partially Premixed Combustion** is the selected **Model** and if the **C Equation** or **G Equation** premixed model is chosen.)

Turbulent Length Scale Constant
specifies the value of C_D in Equation 9.11 in the Theory Guide.

Turbulent Flame Speed Constant
specifies the value of A in Equation 9.9 in the Theory Guide.

Stretch Factor Coefficient
specifies the value of μ_{str} in Equation 9.16 in the Theory Guide.

Turbulent Schmidt Number
specifies the value of Sc_t in Equation 9.1 in the Theory Guide.

Wall Damping Coefficient
specifies the value of α_w in Equation 9.19.

Ewald Corrector
is enabled by default and described in Peters Flame Speed Model.

G Equation Settings
allows you to select either the **transport equation** or **algebraic** option for the calculation of the flame distance variance. Consult Peters Flame Speed Model in the Theory guide for the variance transport and algebraic equation expressions (Equation 9.6 and Equation 9.7).

Flame Curvature Source
includes the curvature source term in the G-Equation, which is the last term in Equation 9.4.

Turbulence-Chemistry Interaction
is available if you select **Flamelet Generated Manifold** for the partially premixed combustion model. The three available options (**Finite-Rate**, **Turbulent Flame Speed**, and **Finite-Rate/Turbulent Flame Speed**) are discussed in FGM Turbulent Closure in the Theory Guide.

Variance Settings
is available for the **G Equation** and **C Equation**. (This section will appear only if **Premixed Combustion** or **Partially Premixed Combustion** is the selected **Model**.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Variance Method
contains a drop-down list of the available two options: **transport equation** and **algebraic**. Consult Peters Flame Speed Model in the Theory Guide for the variance transport and algebraic equation expressions (Equation 9.6 and Equation 9.7). It is recommended that you use the **transport equation** option for RANS and the **algebraic** option for LES.

Premixed Combustion Model Options
contains options for the premixed combustion model. (This section will appear only if **Premixed Combustion** is the selected **Model**.)

Adiabatic
enables the adiabatic premixed combustion model, which calculates temperature using Equation 9.65 in the Theory Guide.

Non-Adiabatic
enables the non-adiabatic premixed combustion model, which calculates temperature using Equation 9.66 in the Theory Guide.

Premixed Model
contains options for choosing a premixed model.

C Equation
allows you to choose the C equation as described in C-Equation Model Theory.

Extended Coherent Flamelet Model
allows you to choose the Extended Coherent Flamelet model as described in Extended Coherent Flamelet Model Theory.

G Equation
allows you to choose the G equation as described in G-Equation Model Theory.

Extended Coherent Flamelet Model Constants
contains model constants for the Extended Coherent Flame Model. (This section will appear only if **Premixed Combustion** or **Partially Premixed Combustion** is the selected **Model** and if the **Extended Coherent Flame Model** flame speed model is chosen.) See Modifying the Constants for the ECFM Flame Speed Closure (p. 1095) for details.

ITNFS Treatment
contains a drop-down list of the available ITNFS treatments: **constant-delta**, **meneveau**, **blint**, **poinsot**, and **constant**.

ITNFS Flame Thickness
sets the flame thickness (Equation 9.29 in the Theory Guide).

Turbulent Schmidt Number
set the turbulent Schmidt number (Sc_t).

Wall Flux Coefficient
set the wall flux coefficient.

PDF Transport Options
contains options for the Composition PDF Transport combustion model. (This section will appear only if **Composition PDF Transport** is the selected **Model**.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lagrangian
solves the composition PDF transport equation by stochastically tracking Lagrangian particles through the domain.

Eulerian
assumes a shape for the PDF, allowing Eulerian transport equations to be derived.

Mixing
tab contains the mixing models.

Mixing Model
contains options to specify the method for modeling molecular diffusion. (This section will appear only if **Composition PDF Transport** is the selected **Model**.) See Particle Mixing in the Theory Guide for details.

Modified Curl
enables the modified curl model for molecular diffusion.

IEM
enables the IEM model for molecular diffusion.

EMST
enables the EMST mixing model for molecular diffusion.

Mixing Constant
specifies the value of the mixing constant C_φ in Equation 11.6 and Equation 11.8 in the Theory Guide.

Boundary
tab allows you to define the fuel and oxidizer compositions. This is only available if you select **Eulerian** as the **PDF Transport Option**.

Species
consists of the fuel species and the oxidizer.

Fuel
is the mole or mass fraction of the fuel stream. The sum of mass or mole fractions of all species in the fuel stream should be 1.

Oxidizer
is the mole or mass fraction of the oxidizer stream. The sum of mass or mole fractions of all species in the fuel oxidizer stream should be 1.

Specify Species in
specifies the species as a **Mass Fraction** or **Mole Fraction**.

Control
tab contains Lagrangian PDF transport parameters.

PDF Transport Parameters
allows you to set the **Particles Per Cell**.

Particles Per Cell
sets the number of PDF particles per cell. Higher values of this parameter will reduce statistical error, but increase computational time.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Local Time Stepping
toggles the calculation of local time steps. If this option is disabled, then you will need to specify the **Time Step** directly (see Equation 11.4 in the Theory Guide). This option is available for steady-state simulations.

Convection #
specifies the particle convection number (see Δt_{conv} in Equation 11.4 in the Theory Guide).

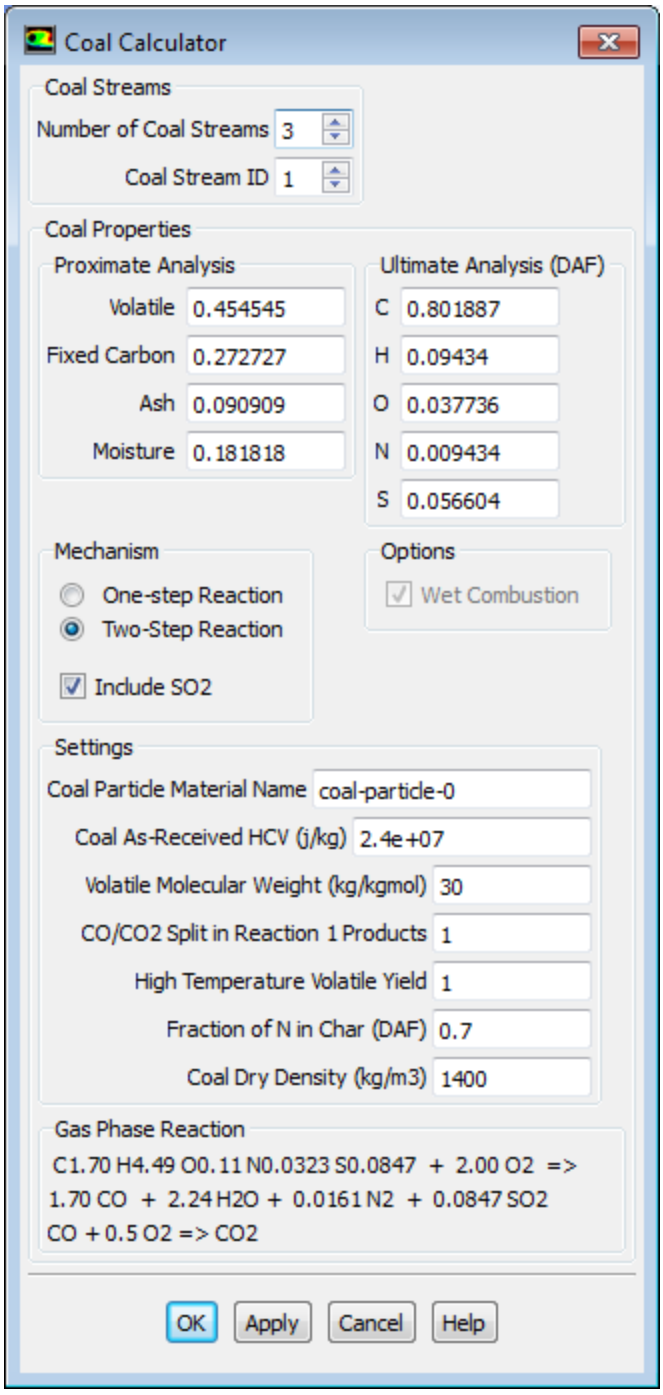
Diffusion #
specifies the particle diffusion number (see Δt_{diff} in Equation 11.4 in the Theory Guide).

Mixing #
specifies the particle mixing number (see Δt_{mix} in Equation 11.4 in the Theory Guide).

37.4.19. Coal Calculator Dialog Box

The **Coal Calculator** dialog box (opened by clicking **Coal Calculator...** in the **Species Model** dialog box) automates the calculations described in Additional Coal Modeling Inputs in ANSYS Fluent (p. 1049).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Coal Streams

allows you to set up to three coal streams (Species Transport model only).

Number of Coal Streams

specifies the total number of coal streams.

ID

sets the ID of the coal stream for which you want to specify **Coal Properties**.

Coal Properties

contains inputs for the current coal stream.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Proximate Analysis
is the mass fraction of **Volatile**, **Fixed Carbon**, **Ash**, and **Moisture** in the coal.

Volatile
is the fraction of the volatile component.

Fixed Carbon
is calculated as one minus the sum of the actual **Volatile**, **Ash**, and **Moisture** fractions.

Ash
is the fraction of ash.

Moisture
is the moisture fraction in the coal.

Ultimate Analysis (DAF)
is the mass fraction of atomic **C, H, O, N** and optionally **S**, in the Dry-Ash-Free (DAF) coal.

Mechanism
allows you to set the mechanisms.

Secondary Stream
when enabled, allows you to set the two mixture fraction model with the primary stream representing char as C <s> , and an empirical secondary stream representing the volatiles. This is available when using the non-premixed combustion model.

One-step Reaction
is defined in Equation 14.6 (p. 988).

Two-step Reaction
involves oxidation of volatiles to CO in the first reaction and oxidation of CO to CO_2 in the second reaction, as described in Equation 14.7 (p. 988).

Include SO2
when enabled, allows you to specify the atomic mass fraction of sulphur, **S**, which appears under **Ultimate Analysis**.

Options

Wet Combustion
when enabled will enable the DPM **Wet Combustion** option by default in all injections created after the **OK** button is clicked in the **Coal Calculator** dialog box.

Settings
is where you will specify the values used in the calculation.

Coal Particle Material Name
is the name of the DPM combusting particle material. The default name is *coal-particle*.

Coal As-Received HCV
is the higher caloric value of the coal.

Volatile Molecular Weight
is the molecular weight of pure volatiles.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CO/CO2 Split in Reaction 1 Products
can be used to specify the molar fraction of CO to CO_2 in the first reaction of Equation 14.7 (p. 988). The default value of 1 implies that all carbon is reacted to CO, with no CO_2 produced.

High Temperature Volatile Yield
is where the enhanced devolatization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction.

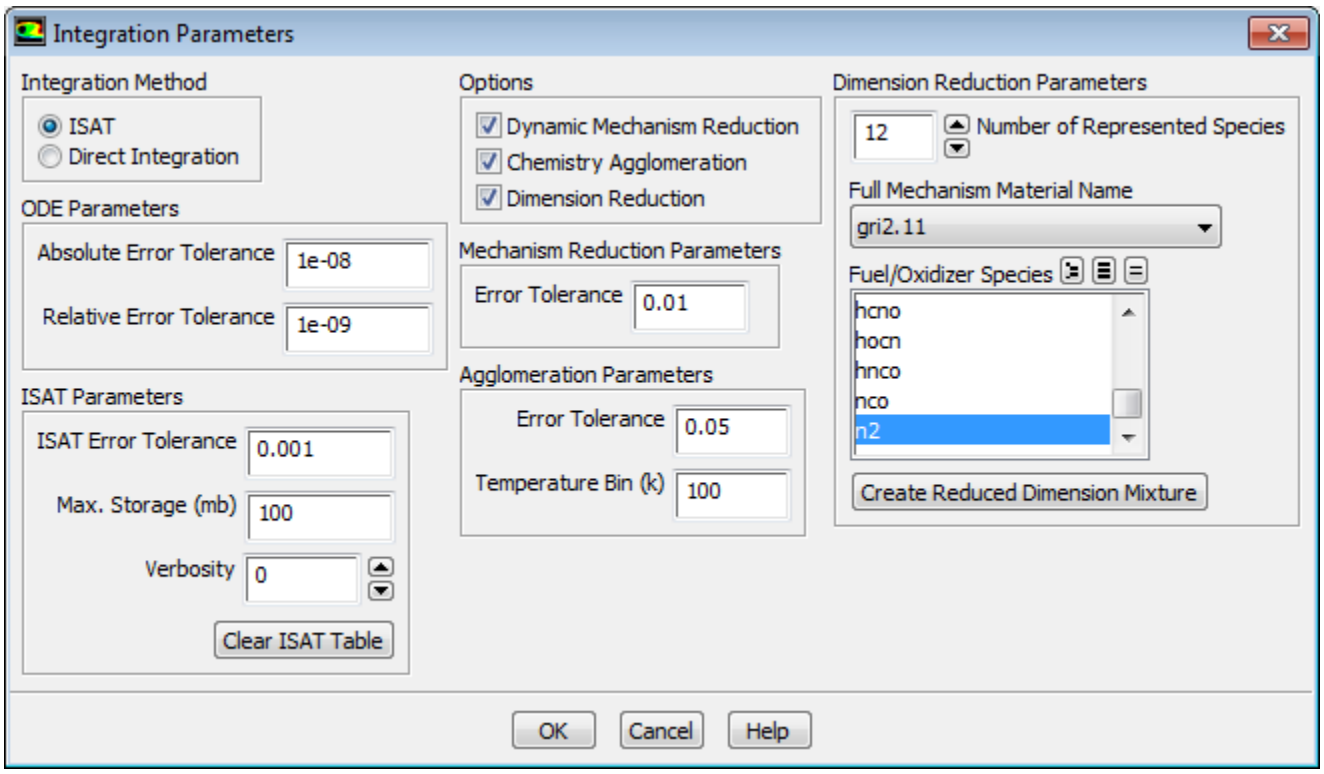
Fraction of N in Char (DAF)
is used in calculating the split of atomic nitrogen for the Fuel NOx model.

Coal Dry Density
is used to calculate the **Volume Fraction** of liquid-water for the **Wet Combustion** option in the **Injections** dialog box.

Gas Phase Reaction
lists the reaction based on your entries for the proximate and ultimate analyses.

37.4.20. Integration Parameters Dialog Box

The **Integration Parameters** dialog box allows you to set the parameters for the integration of the chemical source term S in Equation 11.10 in the Theory Guide. See Using ISAT (p. 1128) for details.



Integration Method
contains options to choose the method for integration.

ISAT
enables the ISAT option and expands the dialog box to include inputs for **ISAT Parameters**.

Direct Integration
enables the direct integration method to integrate the chemical source term in the calculation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ODE Parameters
contains options to specify the error tolerances.

Absolute Error Tolerance
specifies the absolute error tolerance.

Relative Error Tolerance
specifies the relative error tolerance.

ISAT Parameters
contains inputs required for ISAT integration method.

ISAT Error Tolerance
controls the numerical error in ISAT liner interpolation. Decrease this value to get accurate minor species and pollutant predictions.

Max. Storage
is the maximum RAM used by the ISAT table, and has a default value is 100 MB.

Verbosity
specifies the level of detail at which you can monitor the ISAT performance.

Clear ISAT Table
purges the ISAT table.

Options
contains options to choose the method for chemistry acceleration.

Dynamic Mechanism Reduction
accelerates chemistry by reducing the chemical kinetics mechanism on-the-fly to include only important species and reactions, with a corresponding decrease in accuracy. This method is available for **Stiff Chemistry Solver** only.

Chemistry Agglomeration
when enabled, provides additional run-time improvement, with a corresponding decrease in accuracy. This method is available for **Stiff Chemistry Solver** and **Relax to Chemical Equilibrium** only.

Dimension Reduction
is a chemistry acceleration method in addition to ISAT storage-retrieval and Cell Agglomeration, providing faster chemistry calculations with a corresponding loss of accuracy. This method is available for **Stiff Chemistry Solver** only.

Dynamic Cell Clustering
(transient flow) enables a computationally efficient dynamic cell clustering method (DCC) that groups computational cells of high similarity into clusters using two DCC parameters:
- **Max. Temperature Dispersion** (default =10 K)
- **Max. Equiv. Ratio Dispersion** (default =0.05)

This option is enabled by default and recommended. It is available only with the **CHEMKIN-CFD Solver**.

Agglomeration Parameters
contains settings for the agglomeration chemistry method.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Error Tolerance
determines the size of the clusters for species. By default, the value is 0.05.

Temperature Bin
specifies the maximum bin size for temperature. The default value is 100 K.

Dimension Reduction Parameters
contains settings to accelerate the chemistry.

Number of Represented Species
must be greater than 10 and less than the number of species in the full mechanism. The **Number of Represented Species** must also be less than 50 minus the number of unrepresented elements (the number of chemical elements in the unrepresented species).

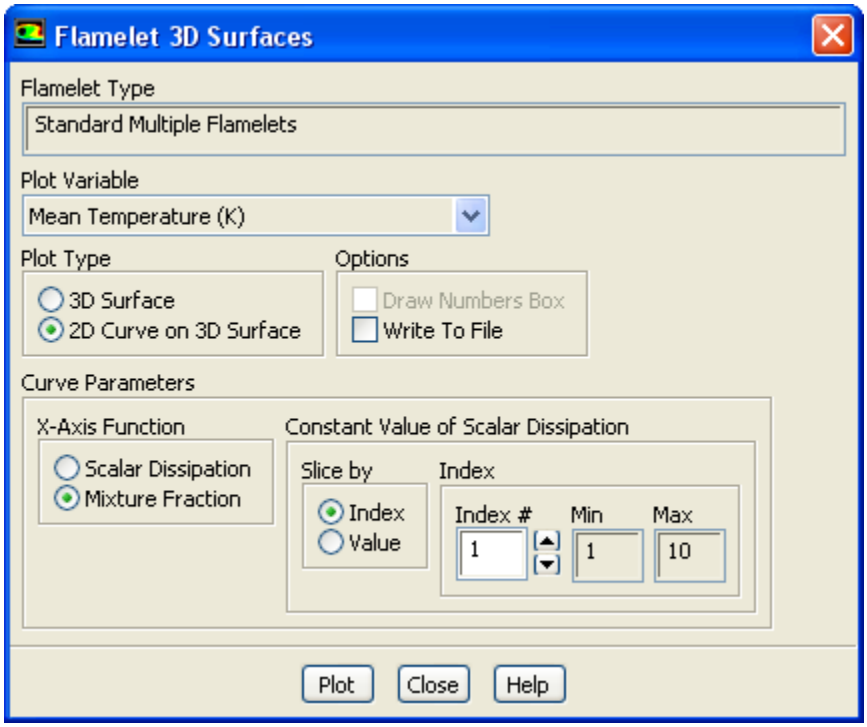
Full Mechanism Material Name
is typically the name of the CHEMKIN mechanism that you imported.

Fuel/Oxidizer Species
is where the boundary and initial fuel and oxidizer, as well as product species, are set as represented species.

Create Reduced Dimension Mixture
creates a new mixture material called `reduced-dimension-mixture`, which contains the represented species as well as proxy 'species' for the unrepresented elements.

37.4.21. Flamelet 3D Surfaces Dialog Box

The **Flamelet 3D Surfaces** dialog box allows you to display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation. See Postprocessing the Flamelet Data (p. 1060) for details.



Flamelet Type
indicates the type of flamelets whose surfaces will be displayed.

Plot Variable
enables you to choose temperature or species fraction as the variable to be plotted.

Plot Type
consists of options for plot type.

3D Surface
enables plotting on 3D surfaces.

2D curve on 3D surface
enables plotting of a 2D curve on a 3D surface.

Options
consists of the following parameters:

Draw Numbers Box
enables the display of a wireframe box with the numerical limits in each coordinate direction.

Write To File
enables saving the plot data to a file.

Curve Parameters
consists of controls related to plot display.

X-Axis Function
consists of the function against which the plot variable will be displayed.

Scalar Dissipation
enables display of plot variable against the scalar dissipation function.

Mixture Fraction
enables display of plot variable against the mixture fraction.

Constant Value of Scalar Dissipation
consists of the controls to specify the type of discretization (that is, how the flamelet data will be sliced) for the variable that is being held constant.

Slice by
consists of the controls to specify discretization.

Index
enables you to specify discretization index of the variable that is being held constant.

Value
enables you to specify the numerical value of the variable that is being held constant.

Index
consists of the controls that are displayed when you enable **Index** under **Slice by**.

Index #
displays the index number.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Min
displays the minimum of the range of integer values that you are allowed to choose from.

Max
displays the maximum of the range of integer values that you are allowed to choose from.

Value
consists of the controls that are displayed when you enable **Value** under **Slice by**.

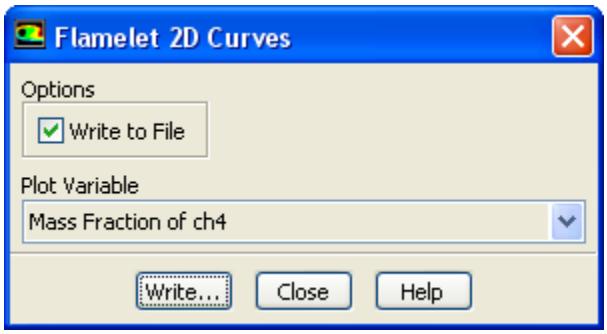
Value
enables you to enter the numerical value of the variable that is being held constant.

Min
displays the minimum of the range of integer values that you are allowed to choose from.

Max
displays the minimum of the range of integer values that you are allowed to choose from.

37.4.22. Flamelet 2D Curves Dialog Box

The **Flamelet 2D Curves** dialog box allows you to display or write 2D curves of the unsteady flamelet. See Postprocessing the Flamelet Data (p. 1060) for details.



Options
gives you the option to plot or **Write to File** 2D curves.

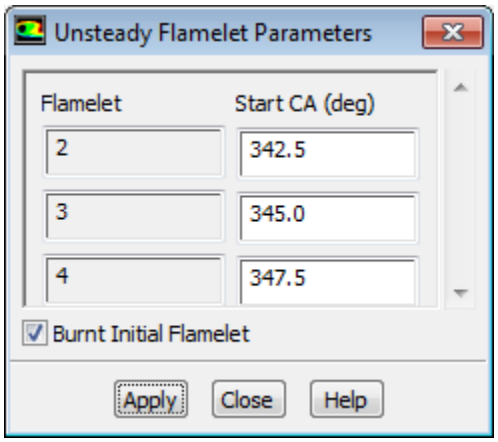
Plot Variable
consists of a drop-down list of variables that you can plot or write.

Plot
is available by default. When the **Write to File** option is enabled the **Plot** button changes to a **Write...**.

37.4.23. Unsteady Flamelet Parameters Dialog Box

The **Unsteady Flamelet Parameters** dialog box (opened by clicking **Set Flamelet Parameters** in the **Flamelet** tab of the **Species Model** dialog box) allows you to specify the initiation time of the unsteady flamelets. See Using the Diesel Unsteady Laminar Flamelet Model (p. 1038) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

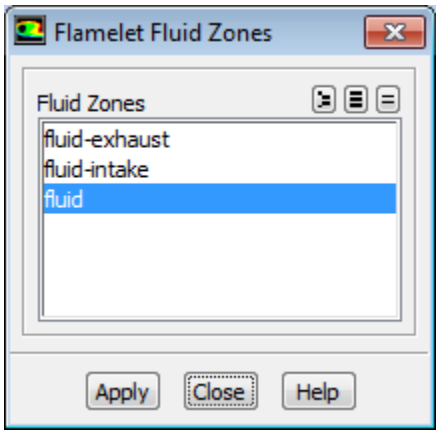


Start CA (deg)
is the time at which each unsteady laminar flamelet will be generated during your simulation. The time is specified in terms of seconds or degrees of crank angle if the dynamic mesh is enabled.

Burnt Initial Flamelet
if enabled, sets the initial flamelet condition to a chemical equilibrium burnt state. Otherwise, the initial flamelet condition is set to unburnt state (default).

37.4.24. Flamelet Fluid Zones Dialog Box

The **Flamelet Fluid Zones** dialog box allows you to select the fluid zones for computing zone-averaged pressure and scalar dissipation. The dialog box is opened by clicking **Set Flamelet Fluid Zones** in the **Flamelet** tab of the **Species Model** dialog box. See Using the Diesel Unsteady Laminar Flamelet Model (p. 1038) for details.



Fluid Zones
is a selectable list of the fluid zones over which the average pressure and scalar dissipation are computed.

37.4.25. PDF Table Dialog Box

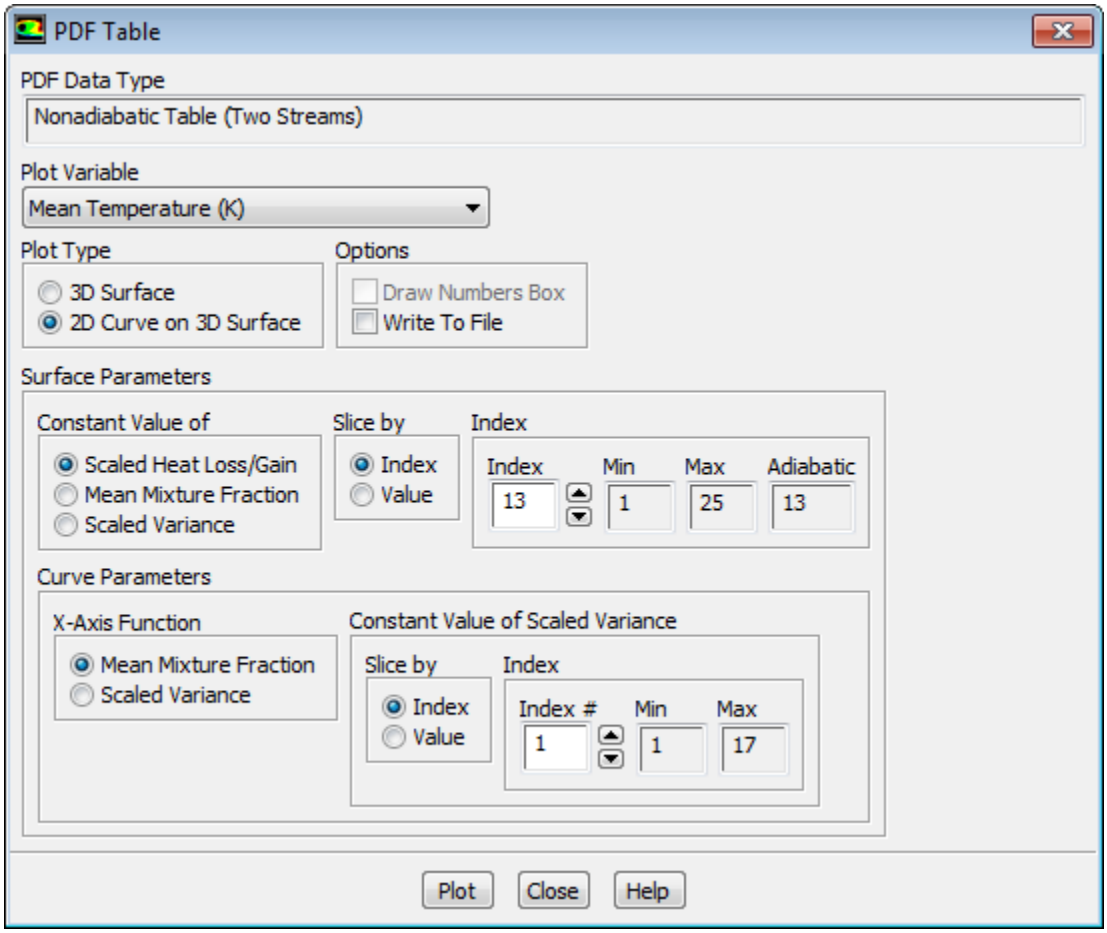
You can display 2D plots and 3D surfaces showing the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy. For the Flamelet Generated Manifold (FGM) model, additional variables are available for generating plots for PDF lookup tables. See Postprocessing the Look-Up Table Data (p. 1068) for details about the items below.

The **PDF Table** dialog box can be accessed in one of two ways:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- by clicking the **Display PDF Table...** button in the **Table** tab of the **Species Model** dialog box (as shown in Figure 15.23: The Species Model Dialog Box (Table) Tab Excluding Automated Grid Refinement (p. 1065))
- by using the following path:

  Postprocessing → **Model Specific** → **PDF Table...**



Controls

PDF Data Type

describes the system that you are displaying.

Plot Variable

contains a drop-down list from which you can select temperature, density, or species mole fraction as the variable to be plotted. For the FMG model, you can also select mean rate of reaction progress.

Enthalpy Slice, Adiabatic = *slice number*

(FGM model only) specifies the value of the enthalpy slice level. By default, the enthalpy level is fixed at the adiabatic level displayed in the label as **Adiabatic = *slice number***. Enthalpy slice numbers below the adiabatic slice number are associated with heat loss, while enthalpy slice numbers above the adiabatic slice number are associated with enthalpy gain.

Scalar Dissipation

(multiple flamelets only) specifies the value of the **Scalar Dissipation**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plot Type
gives you the choice of plotting a 3D surface or a slice of a 3D surface.

3D Surface
displays a 3D plot of the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy.

2D Curve on 3D Surface
consists of a 2D curve that is a slice of a 3D surface.

Options
contains options specific to the display of 3D surfaces or 2D curves on 3D surfaces.

Draw Numbers Box
enabling this option displays a wireframe box with the numerical limits in each coordinate direction. This option is available only when **3D Surface** is selected.

Write To File
specifies whether you want to write the plot data to a file. This option is available only when **2D Curve on 3D Surface** is selected. The **Plot** button changes to a **Write** button when this option is enabled.

Volume Parameters
(FGM model only) contains settings for selecting and fixing a discrete independent variable.

Constant Value of
contains the discrete independent variables that can be held constant in the lookup table. The choices are **Mean Reaction Progress**, **Scaled Reaction Progress Variance**, **Mean Mixture Fraction**, and **Scaled Variance**.

Slice by
allows you to select whether the 3D array of data points available in the look-up table will be sliced by **Index** or **Value**.

Index/Value
contains index/values and their ranges.

Index/Value
allows you to specify the discretization index or numerical value of the variable that is being held constant.

Min/Max
are the range of integer values that you are allowed to choose from or display.

Surface Parameters
contains settings where discrete independent variables are held constant and where curve parameters are defined.

Constant Value of
contains the discrete independent variables that can be held constant in the lookup table. The choices are **Scaled Heat Loss/Gain**, **Mean Mixture Fraction**, and **Scaled Variance**. For a two-mixture-fraction case, the **Scaled Heat Loss/Gain** is the only available option. For the FGM model, this group box contains the discrete independent variables that have not been fixed in the **Volume Parameters** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Slice by
allows you to select whether the 3D array of data points available in the look-up table will be sliced by **Index** or **Value**.

Index/Value
contains index/values and their ranges.

Index/Value
allows you to specify the discretization index or numerical value of the variable that is being held constant.

Min/Max
are the range of integer values that you are allowed to choose from or display.

Adiabatic
is the enthalpy slice index corresponding to the adiabatic case for which the enthalpy (**Scaled Heat Loss/Gain**) is held constant.

Curve Parameters
allows you to specify the **X-Axis Function** against which the plot variable will be displayed when **2D Curve on 3D Surface** is selected.

X-Axis Function
contains the remaining discrete independent parameters that have not been fixed yet.

Constant Value of *`Independent Parameter`*
allows you to specify the type of discretization for the variable that is being held constant using the controls in the **Slice by** and **Index/Value** group boxes. These items are similar to those described above.

Display
displays the plot variable of the 3D surface.

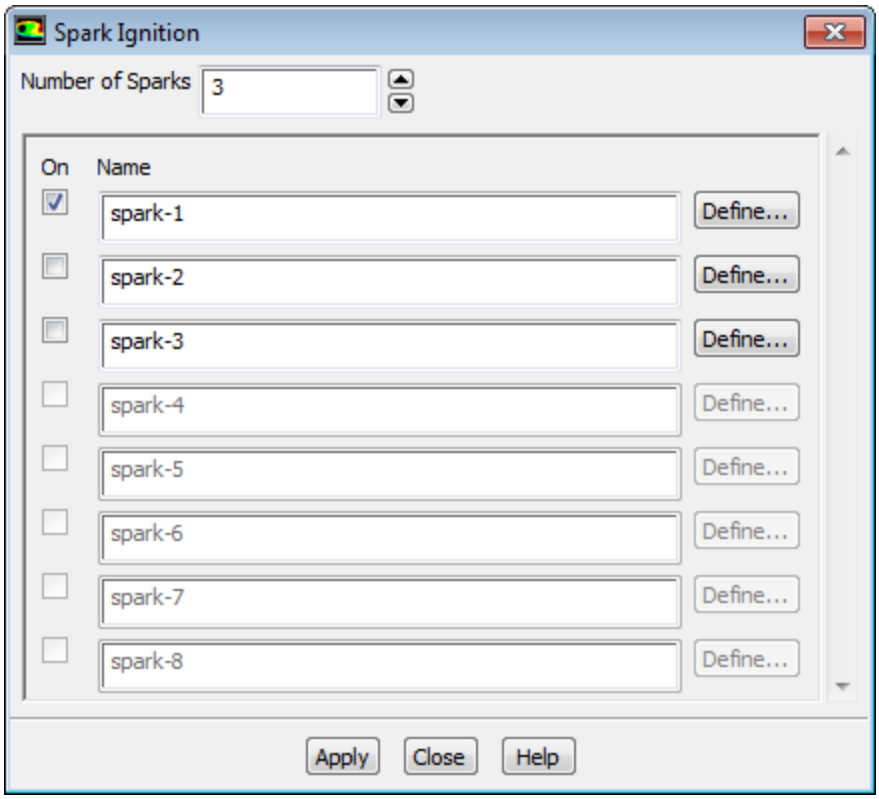
Plot
plots the plot variable for the 2D curve on 3D surface.

Write
opens The Select File Dialog Box (p. 19) where you will specify a name for the file containing plot data. This button appears when **Write To File** is enabled for the **2D Curve on 3D Surface** plot type.

37.4.26. Spark Ignition Dialog Box

The **Spark Ignition** dialog box allows you to define multiple sparks (see Spark Model (p. 1139) for details).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of Sparks
is the quantity of sparks you would like to include in your simulation. You can define up to 16 sparks.

On
if enabled, turns on those sparks that will be included in the simulation.

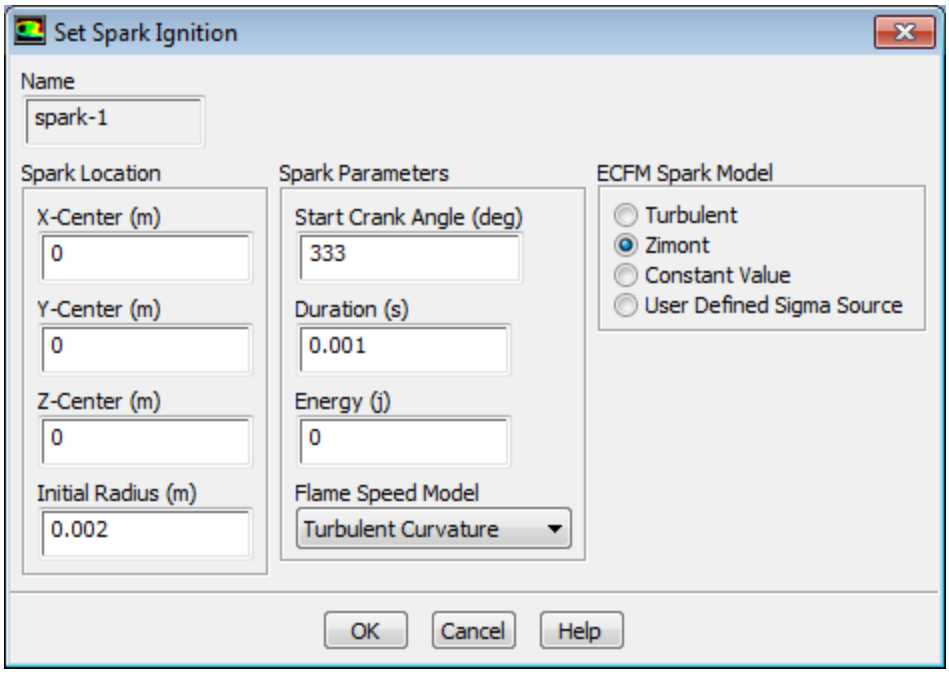
Name
is the name of the spark. You can specify a name, or use the default name.

Define...
opens the Set Spark Ignition Dialog Box (p. 2244).

37.4.27. Set Spark Ignition Dialog Box

The **Set Spark Ignition** dialog box allows you to set the parameters related to the spark ignition model (see Spark Model (p. 1139) for details).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
displays the name of the spark being defined.

Spark Location
contains the parameters needed to define the location and size of the spark.

X, Y, and Z-Center
specifies x, y, and z coordinates of the spark center.

Initial Radius
specifies the initial spark radius.

Spark Parameters
contains the parameters needed to define the spark.

Start Time
is the time of spark ignition initialization in seconds. When the in-cylinder model is turned on, this control is replaced by the **Start Crank Angle** control.

Start Crank Angle
is the time of spark ignition initialization in crank angle degrees. When the in-cylinder model is turned off, this control is replaced by the **Start Time** option.

Duration
is the duration of the spark ignition in seconds.

Energy
contains the total energy input by the spark. The default energy value is 0. A positive value for energy will cause the temperature of the spark kernel to rise above the combustion process temperature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Flame Speed Model
allows you to select the turbulent flame speed model for controlling the rate at which the flame front moves.

Turbulent Curvature
includes the effect of flame curvature as specified in Turbulent Curvature in the *Fluent Theory Guide*.

Turbulent Length
neglects the effects of flame curvature on the flame speed as described in Turbulent Length in the *Fluent Theory Guide*.

Herweg-Maly
calculates the turbulent flame speed using Herweg-Maly model. See Herweg-Maly in the *Fluent Theory Guide* for details.

Laminar
specifies the turbulent flame speed as the laminar flame speed. This option can be used to apply user-defined function (UDF) for the turbulent flame speed definition.

Flame Surface Density
allows you to specify the flame surface density as a constant value when **Constant Value** is selected under **ECFM Spark Model**. The value of the flame surface density must be set within the spark region.

User Sigma Source
allows you to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, refer to Hooking an ECFM Spark Source UDF to ANSYS Fluent in the *Fluent Customization Manual*. This selection is available when **User Defined Sigma Source** is enabled under **ECFM Spark Model**.

ECFM Spark Model
contains model variants used to define the value of the flame surface density. These portions of the dialog box only appear when the **Extended Coherent Flamelet Model** (Setting Up the Extended Coherent Flame Model (p. 1094)) is selected in the **Species Model** dialog box.

Turbulent
takes into account flame wrinkling as described in Turbulent Model in the *Fluent Theory Guide*.

Zimont
operates in the same way as the spark model used with the Zimont combustion model. See Zimont Model in the *Fluent Theory Guide*.

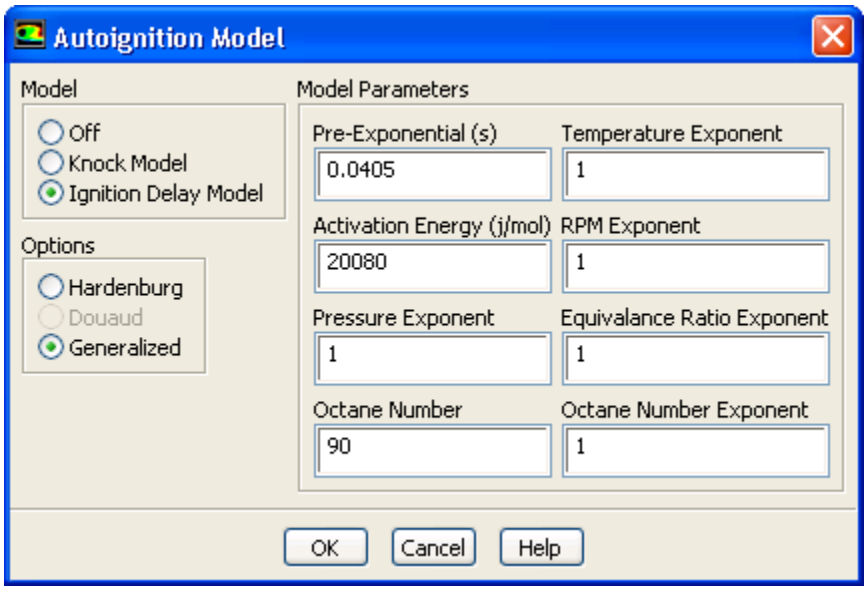
Constant Value
allows you to specify the **Flame Surface Density**.

User Sigma Source
allows you to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel.

37.4.28. Autoignition Model Dialog Box

The **Autoignition Model** dialog box allows you to set the parameters related to the **Knock Model** or the **Ignition Delay Model**. See Modeling Engine Ignition (p. 1139) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model
contains options to disable or enable models.

Off
disables the model.

Knock Model
enables the knock model. With the **Premixed Combustion** or **Partially Premixed Combustion** models selected, only the **Knock Model** can be turned on.

Ignition Delay Model
enables the ignition delay model.

Options
contains two correlation options that exist with each model.

Douaud
option is used for knock in spark ignition engines. The modeling parameters that are specified for this option are the **Pre Exponential**, **Pressure Exponent**, **Activation Temperature**, **Octane Number**, and **Octane Exponent** (Equation 13.9 in the Theory Guide).

Generalized
enables generalized correlation described by Equation 13.10 in the Theory Guide. It requires the same parameters as in the ignition delay model.

Hardenburg
enables Hardenburg correlation, which is used for heavy-duty diesel engines. This option is enabled only for the ignition delay model.

Model Parameters
contains parameters related to the selected model. See Using the Autoignition Models (p. 1143) for the details about the parameters in this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pre-Exponential
see Equation 13.10 and Equation 13.9 in the Theory Guide.

Activation Temperature
see Equation 13.9 in the Theory Guide.

Pressure Exponent
see Equation 13.10 and Equation 13.9 in the Theory Guide.

Octane Number
see Equation 13.10 and Equation 13.9 in the Theory Guide.

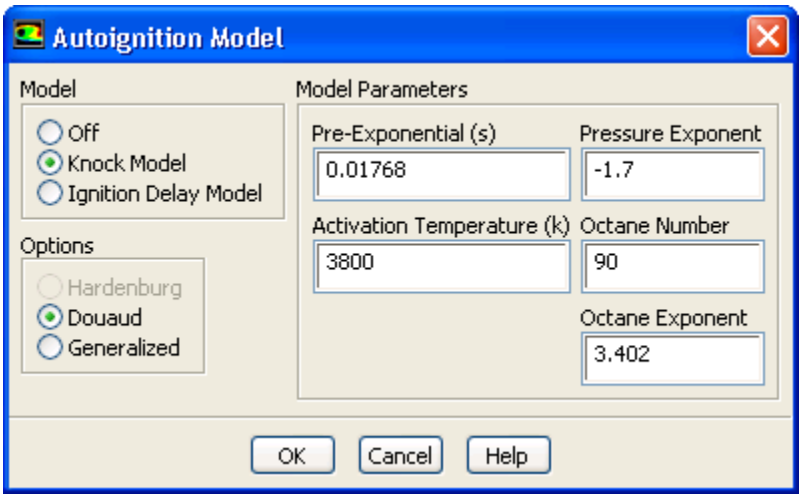
Octane Number Exponent
see Equation 13.10 and Equation 13.9 in the Theory Guide.

Activation Energy
see Equation 13.10 and Equation 13.12 in the Theory Guide.

Temperature Exponent
see Equation 13.10 in the Theory Guide.

RPM Exponent
see Equation 13.10 in the Theory Guide.

Equivalence Ratio Exponent
see Equation 13.10 in the Theory Guide.



Options
contains two correlation options that exist with this model.

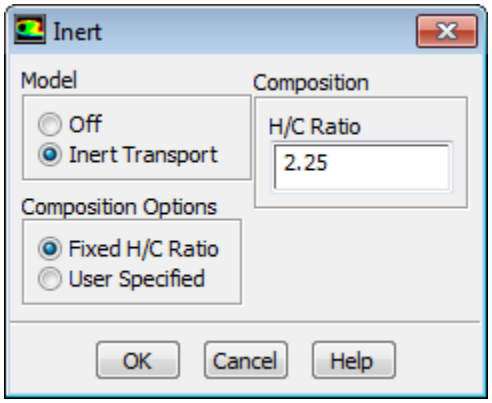
Douaud
enables Douaud correlation (Equation 13.9 in the Theory Guide) used for knock in SI engines.

Generalized
option (Equation 13.10 in the Theory Guide) in the knock model require the same parameters as in the ignition delay model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.4.29. Inert Dialog Box

The **Inert** dialog box allows you to set the parameters related to the inert model. For details, see Setting Up the Inert Model (p. 1075).



Controls

Model
allows you to enable or disable the inert model.

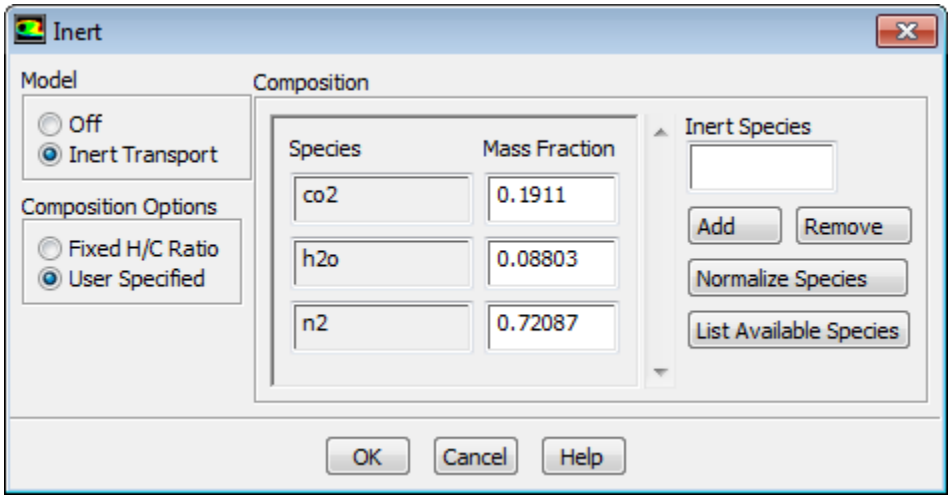
Off
disables the model.

Inert Transport
enables the inert model.

Composition Options
allows you to select a fixed H/C ratio or to specify the composition.

Fixed H/C Ratio
allows you to specify a fixed ratio of hydrogen to carbon in the **H/C Ratio** field.

User Specified
allows you to specify an arbitrary composition for the inert stream.



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Composition
allows you to set the H/C ratio or the mass fraction.

When **Fixed H/C Ratio** is selected under **Composition Options**, the following option(s) are available:

H/C Ratio
specifies the fixed ratio of hydrogen to carbon when the **Fixed H/C Ratio** option is enabled.

When **User Specified** is selected under **Composition Options**, the following option(s) are available:

Species
lists the inert species name.

Mass Fraction
displays the mass fraction of the corresponding species.

Inert Species
allows you to specify the name of the inert species.

Add
adds the specified inert species to the species list.

Remove
removes the specified inert species from the species list.

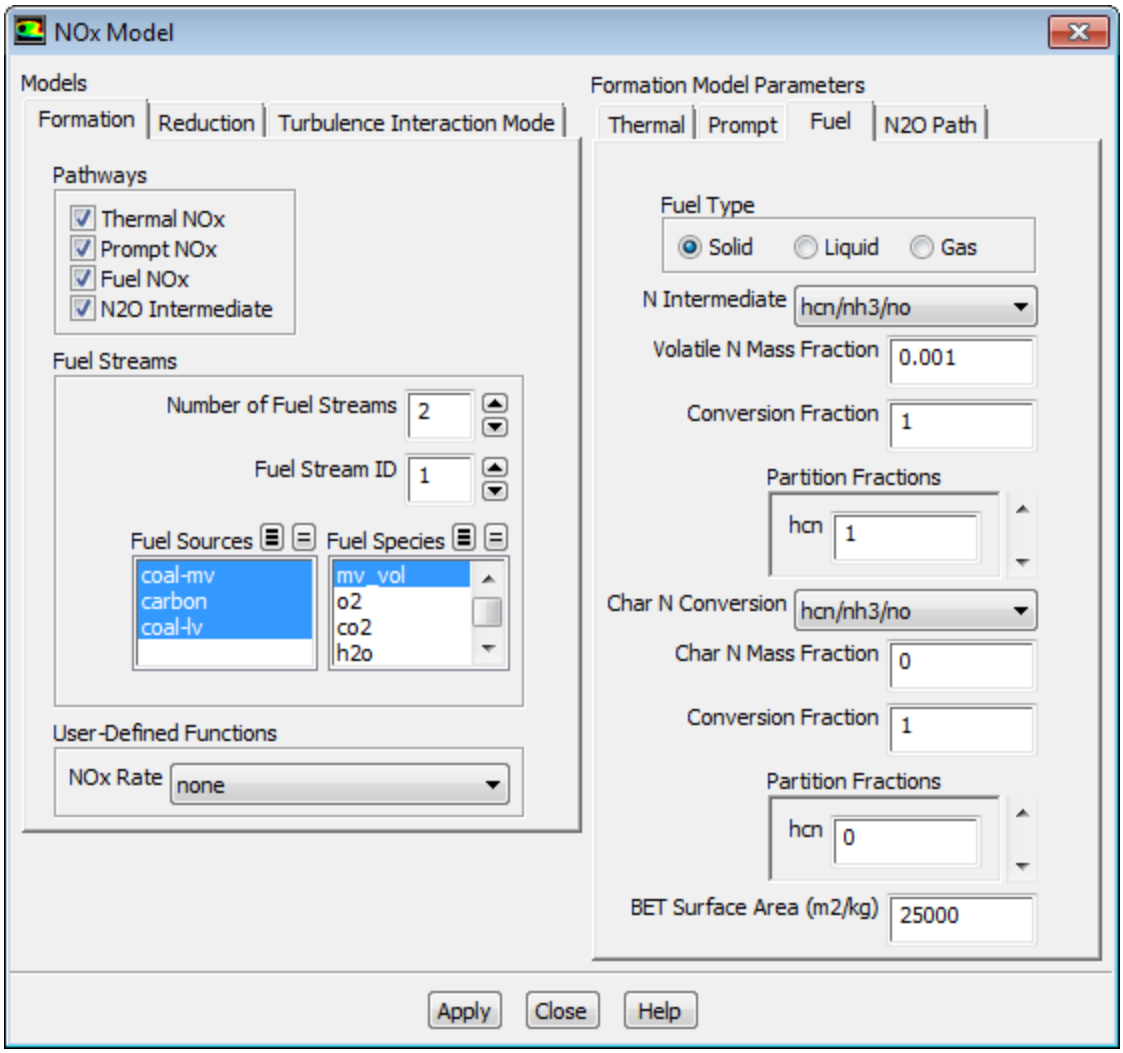
Normalize Species
makes sure the species mass fractions add up to 1.

List Available Species
lists all species in the thermodynamic database file (`thermo.db`) in the console window,

37.4.30. NOx Model Dialog Box

The **NOx Model** dialog box allows you to set parameters related to the NOx postprocessor. See Using the NOx Model (p. 1153) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Models

contains tabs for defining the models used to calculate the NOx production.

Formation

contains the parameters to define the NOx model formation.

Pathways

contains toggle buttons for enabling the NOx models to be used for the calculation of NO and HCN concentrations.

Thermal NOx

enables calculation of thermal NOx.

Prompt NOx

enables the calculation of prompt NOx.

Fuel NOx

enables the calculation of fuel NOx. When using the non-premixed combustion model, the **Fuel NOx** option is only available if the DPM model is also enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

N2O Intermediate
enables the formation of NOx through an N_2O intermediate. This option will only appear if one of the previously listed NOx models is enabled.

Fuel Streams
allows you to define multiple fuel streams for prompt NOx and fuel NOx formation.

Number of Fuel Streams
sets the number of fuel streams. You are allowed up to three fuel streams.

Fuel Stream ID
specifies the fuel stream you are defining in the **PDF Stream** drop-down list, the **Fuel Species** selection list, the **Prompt** tab, and the **Fuel** tab.

PDF Stream
specifies the PDF stream species associated with a particular **Fuel Stream ID**, when calculating fuel NOx formation in conjunction with the non-premixed combustion model. You can select either the **primary** or **secondary** fuel streams, as defined in the PDF table.

Fuel Species
is a list containing all of the defined species, which allows you to specify the species that is the fuel associated with a particular **Fuel Stream ID**. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10. Note that when the non-premixed combustion model is enabled, your selection in the **Fuel Species** list only applies to prompt NOx calculations.

Fuel Sources
is a list containing all of the fuel N sources. This list is available when **Fuel NOx** is enabled and your case contains injections with different DPM materials defined, such as combusting particles and droplets.

User-Defined Functions
contains the **NOx Rate** drop-down list, which allows you to use a user-defined function (UDF) to contribute to the rate of NOx production. See the separate Fluent Customization Manual for details. Note that you may also use a UDF to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

Reduction
allows you to specify the reduction methods.

Methods
contains the list of reduction methods.

Reburn
enables the calculation of NOx reburning effects.

SNCR
enables the calculation of NOx reduction by the SNCR method.

Turbulence Interaction Mode
contains parameters related to the effect of turbulent fluctuations on the NOx formation. See NOx Formation in Turbulent Flows in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PDF Mode
is a drop-down list containing options that take into account turbulent fluctuations when you compute the specified NOx formation. See Setting Turbulence Parameters (p. 1166) for details.

none
specifies the use of laminar NOx rate calculations, so that the effects of turbulence are ignored.

temperature
includes fluctuations of temperature.

temperature/species
includes fluctuations of the temperature and the mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction
includes fluctuations of the mixture fraction(s). This is available for non-premixed combustion calculations only.

PDF Type
allows you to specify the shape of the PDF.

beta
models the PDF using Equation 14.108 in the Theory Guide.

gaussian
models the PDF using Equation 14.111 in the Theory Guide.

PDF Points
controls the number of points at which the beta function in Equation 14.105 or Equation 14.106 in the Theory Guide will be integrated. The default value of 10, which indicates that the beta function will be integrated at 10 points on a histogram basis. The default value should yield an accurate solution with a reasonable computation time. Increasing this value may improve accuracy, but will also increase the computation time. This field is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance
allows you to specify the form of the transport equation that is solved to calculate the temperature variance.

algebraic
is an approximate form of the transport equation (see Equation 14.114 in the Theory Guide).

transported
solves Equation 14.113 in the Theory Guide.

Tmax Option
provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax
sets the limit as the maximum temperature in the flow field.

local-tmax-factor
yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specified-tmax
sets the limit for each cell to be the value entered in **Tmax**.

user-defined
allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a user-defined function and selected it in the **Formation** tab.

Species
is a drop-down list that appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the NOx rate calculations.

Formation Model Parameters
contains the tabs used to define the NOx pathways.

Thermal
contains parameters for modeling thermal NOx. (The contents of this tab will appear only if **Thermal NOx** is enabled in the **Formation** tab.)

[O] Model
is a drop-down list in which you can select the method to be used for calculation of thermal NOx. To choose the equilibrium method, select **equilibrium**. To choose the partial equilibrium method, select **partial-equilibrium**. To choose the predicted O concentration method, select **instantaneous**. See Method 1: Equilibrium Approach, Method 2: Partial Equilibrium Approach, and Method 3: Predicted O Approach in the Theory Guide for details.

[OH] Model
is a drop-down list in which you can select the method to be used for calculation of thermal NOx. To exclude OH, select **none**. To choose the partial equilibrium method, select **partial-equilibrium**. To choose the predicted OH concentration method, select **instantaneous**. See Method 1: Exclusion of OH Approach, Method 2: Partial Equilibrium Approach, and Method 3: Predicted OH Approach in the Theory Guide for details.

UDF Rate
provides options for the treatment of the NOx production specified by the user-defined function selected in the **Formation** tab.

Replace Fluent Rate
replaces ANSYS Fluent's thermal NOx rate calculations with the custom NOx rate produced by your user-defined function.

Add to Fluent Rate
adds the custom NOx rate produced by your user-defined function to ANSYS Fluent's thermal NOx rate calculations.

Prompt
contains parameters for modeling prompt NOx. (The contents of this tab will appear only if **Prompt NOx** is enabled in the **Formation** tab.) The settings made in this tab will be associated with a particular fuel stream, specified in the **Fuel Stream ID** field in the **Formation** tab.

Fuel Carbon Number
specifies the number of carbon atoms per fuel molecule.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Equivalence Ratio
is the ratio of the actual fuel/air ratio to the stoichiometric fuel/air ratio.

UDF Rate
provides options for the treatment of the NOx production specified by the user-defined function selected in the **Formation** tab.

Replace Fluent Rate
replaces ANSYS Fluent's prompt NOx rate calculations with the custom NOx rate produced by your user-defined function.

Add to Fluent Rate
adds the custom NOx rate produced by your user-defined function to ANSYS Fluent's prompt NOx rate calculations.

Fuel
contains parameters for modeling fuel NOx. (The contents of this tab will appear only if **Fuel NOx** is enabled in the **Formation** tab.) The settings made in this tab will be associated with a particular fuel stream, specified in the **Fuel Stream ID** field in the **Formation** tab.

Fuel Type
specifies the type of fuel NOx to be calculated.

Solid
enables the calculation of solid fuel NOx.

Liquid
enables the calculation of liquid fuel NOx.

Gas
enables the calculation of gas fuel NOx.

N Intermediate
allows you to specify any one of the **hcn**, **nh3**, or **hcn/nh3/no** as the intermediate species. See Fuel NOx Formation in the Theory Guide for details.

Volatile N Mass Fraction
specifies the mass fraction of nitrogen in the volatiles. This parameter appears only for **Solid** fuel NOx calculations.

Fuel N Mass Fraction
specifies the mass fraction of nitrogen in the fuel. This parameter appears only for **Gas** or **Liquid** fuel NOx calculations.

Conversion Fraction
specifies the overall mass fraction of fuel N (for gas and liquid fuels), or volatile N or char N (for solid fuels), that will be converted to intermediate species and/or product NO.

Partition Fractions
specifies the mass fraction of the converted fuel N (for gas and liquid fuels), or volatile N or char N (for solid fuels), that will become **hcn** and **nh3**. The fraction that will become NO will be calculated by the remainder. This option will appear only if you have selected **hcn/nh3/no** for the **N Intermediate** or **Char N Conversion** drop-down lists.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Char N Conversion
is a drop-down list in which you can select **no**, **hcn**, **nh3**, or **hcn/nh3/no** as the species to which the char N is converted (when you are calculating solid fuel NOx). This parameter appears only for **Solid** fuel NOx calculations. See Setting Solid (Coal) Fuel NOx Parameters (p. 1161) for details.

Char N Mass Fraction
specifies the mass fraction of nitrogen in the char. This parameter appears only for **Solid** fuel NOx calculations.

BET Surface Area
sets the BET internal pore surface area (see BET Surface Area in the Theory Guide for details) of the particles. This parameter appears only for **Solid** fuel NOx calculations.

UDF Rate
provides options for the treatment of the NOx production specified by the user-defined function selected in the **Formation** tab.

Replace Fluent Rate
replaces ANSYS Fluent's fuel NOx rate calculations with the custom NOx rate produced by your user-defined function.

Add to Fluent Rate
adds the custom NOx rate produced by your user-defined function to ANSYS Fluent's fuel NOx rate calculations.

N2O Path
contains the method to be used for formation of NO through an N_2O intermediate. (The contents of this tab will appear only if **N20 Intermediate** is enabled in the **Formation** tab.)

N2O Model
contains the drop-down list of available N_2O models.

quasi-steady
enables the quasi-steady-state method of calculation (The transport equation for the species N_2O will not be solved).

transported-simple
enables the transported simple method of calculation (The pollutant species N_2O is added in the species list and it's mass fraction will be calculated using the transport equations).

UDF Rate
provides options for the treatment of the NOx production specified by the user-defined function selected in the **Formation** tab.

Replace ANSYS Fluent Rate
replaces the NOx rate calculated by ANSYS Fluent using N_2O intermediates with the custom NOx rate produced by your user-defined function.

Add to ANSYS Fluent Rate
adds the custom NOx rate produced by your user-defined function to the NOx rate calculated by ANSYS Fluent using N_2O intermediates.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reduction Method Parameters
contains tabs that allow you to define the methods of reduction. (These tabs are do not appear unless a reduction method has been enabled in the **Reduction** tab.)

Reburn
allows you to define the NOx reduction when **Reburn** is enabled in the **Reduction** tab.

Reburn Model
contains the drop-down list of reburn methods.

instantaneous[CH]
enables the instantaneous method in the **Reburn Model**. When you choose this method a warning to include CH, CH_2, and CH_3 will be displayed.

partial-equilibrium
activates partial method in the **Reburn Model**.

Reburn Fuel Species
contains reburn fuel species drop-down list.

Equivalent Fuel Type
contains equivalent fuel type drop-down list.

SNCR
allows you to define the NOx reduction when **SNCR** is enabled in the **Reduction** tab.

Injection Method
contains the parameters for NOx reduction by SNCR method.

gaseous
includes ammonia or urea as a gas-phase pollutant species from the injection locations.

liquid
includes ammonia or urea as a liquid-phase pollutant species from the injection locations.

Reagent Species
allows you to specify the reagent species as either ammonia (**nh3**) or urea (**co<nh2>2**)

Reagent Fraction in Stream
allows you to specify the mass fraction of the reagent in the reagent stream. The remaining mass fraction is assumed to be water. If you enabled a secondary stream in your PDF calculation, by default the secondary stream will act as the reagent stream. Note that the **Reagent Fraction in Stream** field is only available when using the non-premixed combustion model with a liquid-phase reagent injection.

Urea Decomposition
allows you to specify the decomposition model to use when the selected **Reagent Species** is **co<nh2>2**.

rate-limiting
specifies that the source terms be calculated according to the rates given in Table 14.3: Two-Step Urea Breakdown Process.

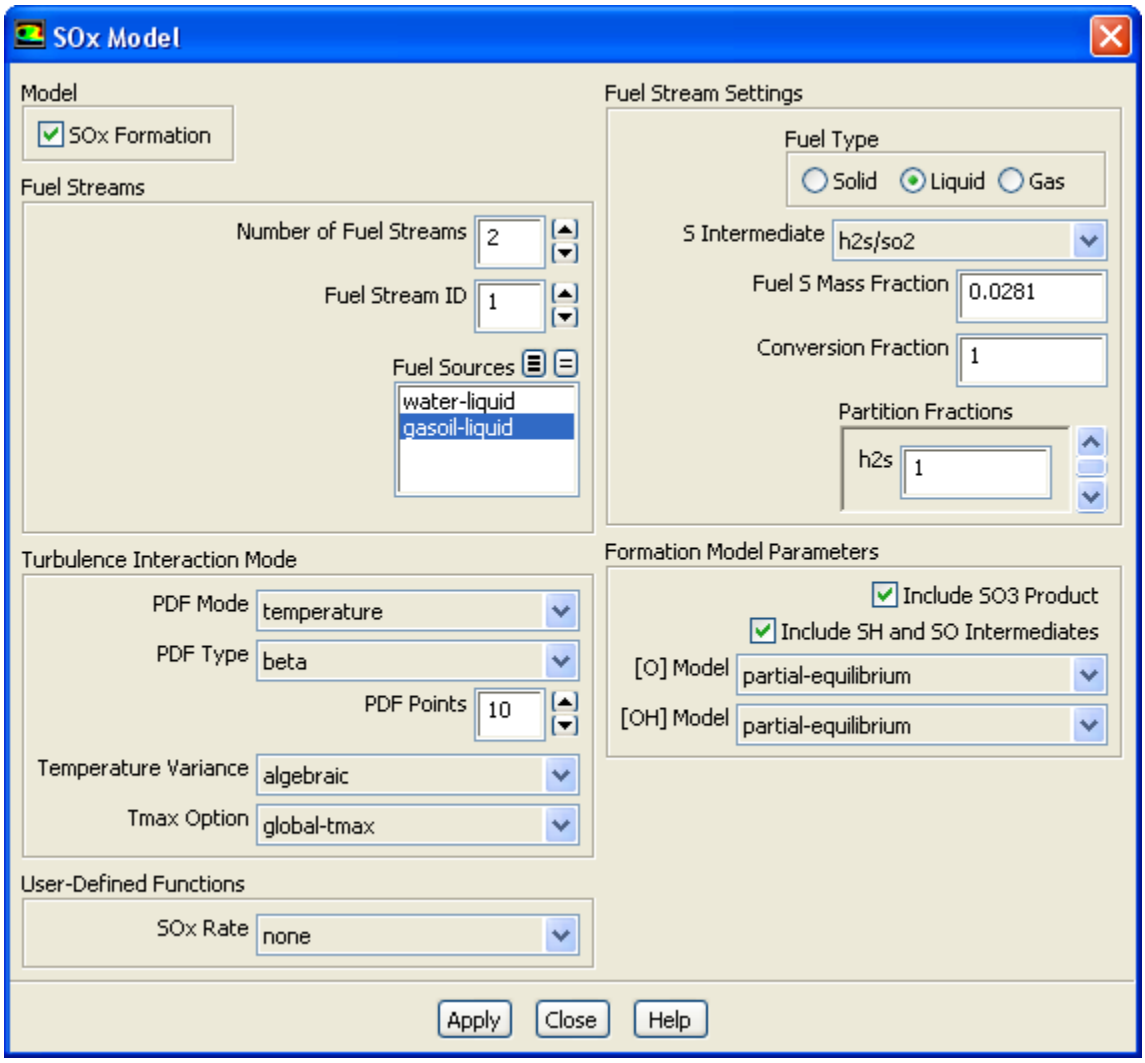
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

user-specified
allows you to specify the molar conversion fraction for ammonia, assuming that the rest of the urea is converted to HNCO.

NH3 Conversion
is the mole fraction of NH_3 in the mixture of NH_3 and HNCO instantly created from the reagent injection. The **NH3 Conversion** field only appears when **user-specified** is selected for **Urea Decomposition**.

37.4.31. SOx Model Dialog Box

The **SOx Model** dialog box allows you to set parameters related to the SOx postprocessor. See Using the SOx Model (p. 1171) for details about the items below.



Controls

Model
contains the control to enable the model.

SOx Formation
enables the model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fuel Streams
allows you to define multiple fuel streams for SOx formation.

Number of Fuel Streams
sets the number of fuel streams. You are allowed up to three fuel streams.

Fuel Stream ID
specifies the fuel stream you are defining in the **Fuel Species** selection list and the **Formation Model Parameters** group box.

Fuel Species
is a list containing all of the defined species. This list is used to specify the species that is the fuel associated with a particular **Fuel Stream ID**, for any combustion model other than non-premixed combustion. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10, the list of fuel species is available when **Gas** is the selected **Fuel Type**.

Fuel Sources
is a list containing all of the fuel S sources. This list is available when **Fuel Type** is **Liquid** or **Solid** and your case contains injections with different DPM materials defined, such as combusting particles and droplets.

PDF Stream ID
specifies the PDF stream species associated with a particular **Fuel Stream ID**, when calculating SOx formation in conjunction with the non-premixed combustion model.

primary
indicates the primary fuel stream species, as defined in the PDF table.

secondary
indicates the secondary fuel stream species, as defined in the PDF table.

Turbulence Interaction Mode
contains parameters related to the effect of turbulent fluctuations on the SOx formation. See SOx Formation in Turbulent Flows in the Theory Guide for details.

PDF Mode
is a drop-down list containing options that take into account turbulent fluctuations when you compute the specified SO_2 formation. See Setting Turbulence Parameters (p. 1166) for details.

none
specifies the use of laminar SOx rate calculations, so that the effects of turbulence are ignored.

temperature
includes fluctuations of temperature.

temperature/species
includes fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction
includes fluctuations of the mixture fraction(s). This is available for non-premixed combustion calculations only.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PDF Type
allows you to specify the shape of the PDF.

beta
models the PDF using Equation 14.108 in the Theory Guide.

gaussian
models the PDF using Equation 14.111 in the Theory Guide.

PDF Points
controls the number of points at which the beta function in Equation 14.105 or Equation 14.106 in the Theory Guide will be integrated. The default value of 10, which indicates that the beta function will be integrated at 10 points on a histogram basis, will yield an accurate solution with reasonable computation time. Increasing this value may improve accuracy, but will also increase the computation time. This field is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance
allows you to specify the form of transport equation that is solved to calculate the temperature variance.

algebraic
is an approximate form of the transport equation (see Equation 14.114 in the Theory Guide).

transported
solves Equation 14.113 in the Theory Guide.

Tmax Option
provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax
sets the limit as the maximum temperature in the flow field.

local-tmax-factor
yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

specified-tmax
sets the limit for each cell to be the value entered in **Tmax**.

user-defined
allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a user-defined function and selected it in the **SOx Rate** drop-down list in the **User-Defined Functions** group box.

Species
is a drop-down list which appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the SOx rate calculations.

User-Defined Functions
allows you to use a user-defined function (UDF) to contribute to the rate of SOx production. See the separate Fluent Customization Manual for details. Note that you may also use a UDF to specify custom values

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

SOx Rate
allows you to select a compiled user-defined function.

UDF Rate
provides options for the treatment of the SOx production specified by the user-defined function.

Replace Fluent Rate
replaces ANSYS Fluent's SOx rate calculations with the custom SOx rate produced by your user-defined function.

Add to Fluent Rate
adds the custom SOx rate produced by your user-defined function to ANSYS Fluent's SOx rate calculations.

Fuel Stream Settings
contains the parameters associated with a particular fuel stream of the SOx model, as specified in the **Fuel Stream ID** field in the **Fuel Streams** group box.

Fuel Type
enables selection of the fuel.

Solid
enables the calculation of solid fuel SOx.

Liquid
enables the calculation of liquid fuel SOx.

Gas
enables the calculation of gas fuel SOx.

S Intermediate
drop-down list enables you to select intermediate species (**h2s**, **so2**, or **h2s/so2**).

Volatile S Mass Fraction
specifies the mass fraction of sulfur in the volatiles. This parameter appears only for **Solid** fuel streams.

Fuel S Mass Fraction
field sets the value for correct mass fraction of sulfur in the fuel (kg sulfur per kg fuel). This parameter appears only for **Liquid** and **Gas** fuel streams.

Conversion Fraction
specifies the overall mass fraction of the fuel S (for liquid or gas fuels), or the volatile S or char S (for solid fuels), that will be converted to the intermediate species and/or product SO_2. The **S Intermediate Conversion Fraction** has a default value of 1.

Partition Fractions
specifies the mass fraction of the fuel S (for liquid or gas fuels), or the volatile S or char S (for solid fuels) that will become **h2s**. The remainder will become SO_2. This parameter only appears when you select **h2s/so2** for the **S Intermediate** or **Char S Conversion** drop-down lists.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Char S Conversion
drop-down list selects the char S conversion path as **so2**, **h2s**, or **so2/h2s**. This parameter appears only for **Solid** fuel streams.

Char S Mass Fraction
specifies the mass fraction of sulfur in the char. This parameter appears only for **Solid** fuel streams.

Formation Model Parameters
allows you to include SOx products and intermediates.

Include SO3 Product
includes **SO3** as a product in all of the fuel streams, as described in Reaction Mechanisms for Sulfur Oxidation in the Theory Guide.

Include SH and SO Intermediaries
includes **SH** and **SO** as intermediates in all of the fuel streams, as described in Reaction Mechanisms for Sulfur Oxidation in the Theory Guide.

[O] Model
drop-down list specifies the method by which **O** will be calculated in all of the fuel streams, that is, **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[O] Model**.

[OH] Model
drop-down list specifies the method by which **OH** will be calculated in all of the fuel streams, that is, **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[OH] Model**.

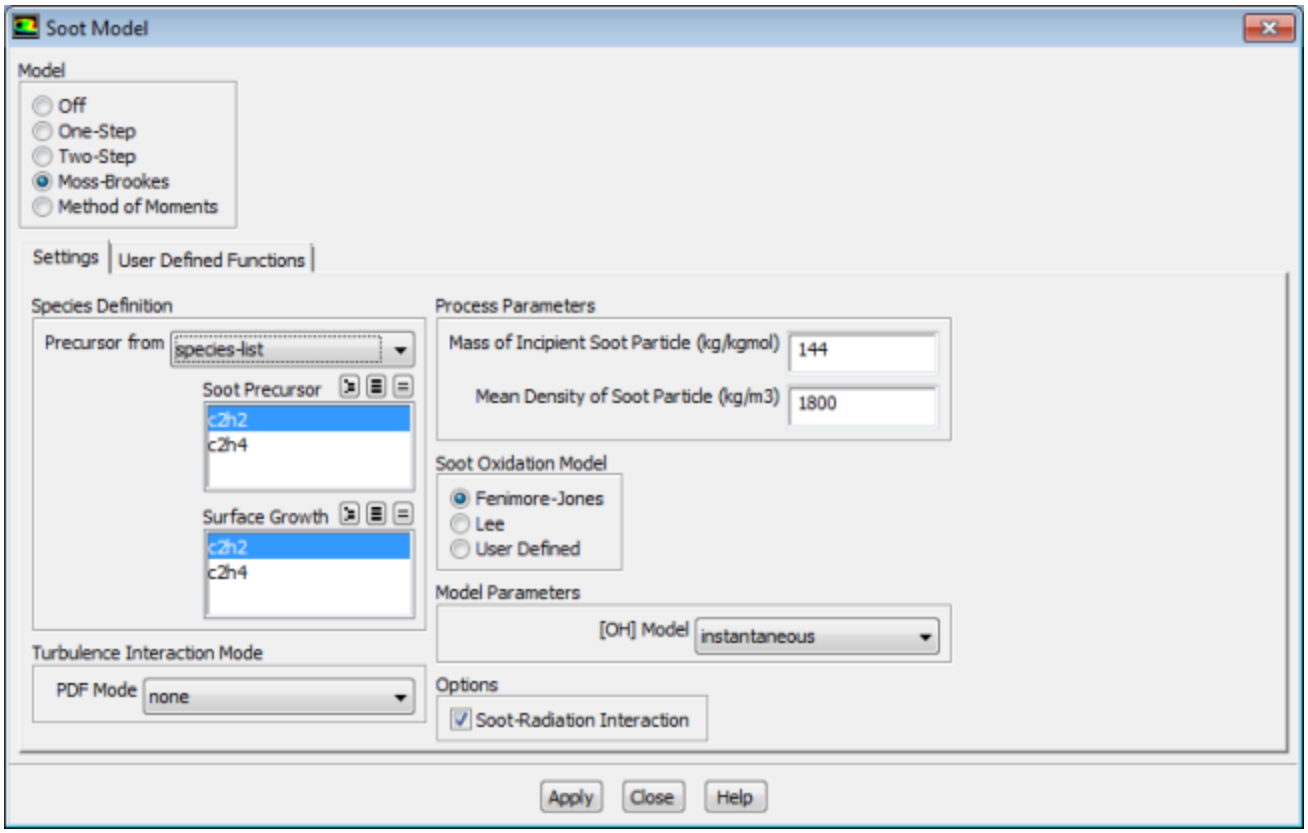
Important

To use the predicted O and/or OH concentration, select **instantaneous** in the **[O] Model** or **[OH] Model** drop-down list.

37.4.32. Soot Model Dialog Box

The **Soot Model** dialog box allows you to set parameters related to the soot model. See Using the Soot Models (p. 1184) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

specifies which model should be used for computing soot formation.

Off

disables the calculation of soot formation.

One-Step

enables the one-step soot model described in The One-Step Soot Formation Model in the Theory Guide.

Two-Step

enables the two-step soot model described in The Two-Step Soot Formation Model.

Moss-Brookes

enables the Moss-Brookes soot model described in The Moss-Brookes Model in the Theory Guide.

Moss-Brookes-Hall

enables the Moss-Brookes-Hall soot model described in The Moss-Brookes-Hall Model in the Theory Guide. This option is only available when C_2H_2, C_6H_6, C_6H_5, and H_2 are present in the gas phase species list.

Method of Moment

enables the Method of Moment soot model described in Setting Up the Method of Moments Soot Model (p. 1196).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Number of Moments
(only for the method of moments soot model) specifies the number of moments to be used in the Method of Moments soot model. ANSYS Fluent will solve an equal number of moment transport equations. The default value of three moments works reasonably well for wide range of problems. You can specify up to six moments.

Species Definition
contains inputs for specifying the chemical species for your model.

Fuel
is a drop-down list containing all of the defined species. Here you will select the species that is the fuel for the **One-Step** and **Two-Step** models, as well as the **Moss-Brookes** model when a precursor species is not identified in the defined species list.

Oxidant
is a drop-down list containing all of the defined species. Here you will select the species that is the oxidizer for the **One-Step** and **Two-Step** models.

Precursor from
allows you to select from a list of species, enter the correlation values of species, or enables you to hook a user-defined function, used to define the user defined precursor species. This selection is available when using the **Moss-Brookes** and **Moss-Brookes-Hall** models.

User Defined Precursor
allows you to hook a user-defined function to specify the user defined soot precursor. This selection is available when using the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Soot Precursor
is a selection list containing all of the possible precursor species found via a query of the defined species list. By default, ANSYS Fluent only considers c2h2, c6h6, and c2h4 as possible precursor species. For information about including other species in the possible precursor species search, contact your ANSYS Fluent support engineer. From this list you will select the species that are the soot precursor species for the **Moss-Brookes**, **Moss-Brookes-Hall**, or **Method of Moments** models.

Surface Growth
is a selection list containing all of the possible surface growth species, as explained previously for the **Soot Precursor** selection list. Here you will select the species that are the surface growth species for the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Fuel Carbon Number
is the number of carbon atoms in the species selected in the **Fuel** drop-down list. This field appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

Fuel Hydrogen Number
is the number of hydrogen atoms in the species selected in the **Fuel** drop-down list. This field appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

Molecular Weight of Precursor
is the molecular weight of the precursor species. This field appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list. The default value is the weight of acetylene.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Precursor Correlation
is a drop-down list you can use to define a laminar diffusion profile that relates mixture fraction to precursor mass fraction. This field appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

piecewise-polynomial
specifies that the precursor mass fraction is a piecewise-polynomial function of mixture fraction. The default values used by ANSYS Fluent correspond to a methane diffusion flame simulation, in which both the air and fuel initial temperatures are set to 290 K, and acetylene is assumed as the soot precursor. These values can be revised via the **Edit...** button.

constant
specifies that the precursor mass fraction is a constant function of mixture fraction, the value of which is specified in the field below the **Precursor Correlation** drop-down list.

Edit...
opens the Piecewise-Polynomial Profile Dialog Box (p. 2319) when **piecewise-polynomial** is selected from the **Precursor Correlation** drop-down list, thus allowing you to revise the default values.

Sticking Coefficients...
(only for the method of moments soot model) opens Sticking Coefficients Dialog Box (p. 2269) where you can provide the correction factors to be used for calculating the nucleation rates. This button is available only when **User Precursor** is the selected soot nucleation model.

Turbulence Interaction Mode
contains inputs that specify how turbulent fluctuations are accounted for in the soot formation calculations for the **Moss-Brookes** and **Moss-Brookes-Hall** models. For further details on these inputs, see Setting Up the Moss-Brookes Model and the Hall Extension (p. 1190).

PDF Mode
is a drop-down list that contains the options for addressing turbulent fluctuations in the soot rate calculations. Note that **mixture fraction** is the most accurate option, and should be used if it is available.

none
specifies the use of laminar soot rate calculations, so that the effects of turbulence are ignored.

temperature
specifies that the soot rate calculations include the effect of temperature fluctuations.

temperature/species
specifies that the soot rate calculations include the effect of fluctuations of temperature, as well as fluctuations of the mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction
is the most accurate option, specifying that the soot rate calculations include the effect of fluctuations of mixture fraction(s). Note that this option is not available if you are using the eddy-dissipation model.

PDF Type
allows you to specify the shape of the PDF.

beta
models the PDF using Equation 14.108 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

gaussian
models the PDF using Equation 14.111 in the Theory Guide.

PDF Points
controls the number of points at which the beta function will be integrated on a histogram basis. Increasing this number may improve accuracy, but will also increase compute time. This field is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance
allows you to specify the form of transport equation that is solved to calculate the temperature variance.

algebraic
is an approximate form of the transport equation (see Equation 14.114 in the Theory Guide).

transported
solves Equation 14.113 in the Theory Guide.

Tmax Option
provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax
sets the limit as the maximum temperature in the flow field.

local-tmax-factor
yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

specified-tmax
sets the limit for each cell to be the value entered in **Tmax**.

user-defined
allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a user-defined function.

Species
is a drop-down list which appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the soot rate calculations.

Process Parameters
contains parameters that control the combustion process modeling.

Mean Diameter of Soot Particle
is the assumed average diameter of the soot particles in the combustion system. For the **Two-Step** model, it is used to compute the soot particle mass m_p in Equation 14.134 in the Theory Guide.

Mean Density of Soot Particle
is the assumed average density of the soot particles in the combustion system. For the **Two-Step** model, it is used to compute the soot particle mass m_p in Equation 14.134 in the Theory Guide. For the **Moss-Brookes** and **Moss-Brookes-Hall** models, it is ρ_{soot} in Equation 14.141 and ρ in Equation 14.144 in the Theory Guide. The default value supplied by ANSYS Fluent is 1800 kg/m^3 (as was used in the work of Brookes and Moss [18] (p. 2887)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Normalization Parameter for Moments
(only for the method of moments soot model) is used to solve the normalized soot moment transport equations to minimize the numerical errors. The default value of this input is sufficient and you may not need to change this.

Stoichiometry for Soot Combustion
is the mass stoichiometry ν_{soot} in Equation 14.131 in the Theory Guide, which computes the soot combustion rate in the **One-Step** and **Two-Step** models. The default value supplied by ANSYS Fluent (2.6667) assumes that the soot is pure carbon and that the oxidizer is O_2.

Stoichiometry for Fuel Combustion
is the mass stoichiometry ν_{fuel} in Equation 14.131 in the Theory Guide, which computes the soot combustion rate in the **One-Step** and **Two-Step** models. The default value supplied by ANSYS Fluent (3.6363) is for combustion of propane ($C_3 H_8$) by oxygen (O_2).

Mass of Incipient Soot Particle
is M_P in Equation 14.142 and Equation 14.144, which is used in the **Moss-Brookes** and **Moss-Brookes-Hall** model computations. The default value supplied by ANSYS Fluent (144 kg/mol) is the mass of 12 carbon atoms. Note that for the original implementation of the Hall extension, the model assumed this mass to be 100 carbon atoms.

Soot Oxidation Model
contains model options that determine the form of the soot oxidation term in the calculations of the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Fenimore-Jones
takes into account the soot oxidation due to the hydroxyl radical.

Lee
takes into account the soot oxidation due to the hydroxyl radical and molecular oxygen.

User Defined
enables you to select a user-defined function for soot oxidation rate. This selection is available when using the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Soot Nucleation Model
(only for the method of moments soot model) contains model options related to soot nucleation modeling.

Use Precursor
enables you to define the precursor species. The nucleation rates are calculated considering coagulation between precursor species using kinetic theory.

Specify Mechanism
enables you to specify nucleation in terms of reactions.

User Defined Oxidation Rate
allows you to hook the user-defined function to specify the soot oxidation rate. This selection is available when using the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Model Parameters
contains parameters that control the soot formation model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Soot Formation Constant
is the parameter C_s in Equation 14.128 in the Theory Guide. This item appears only for the **One-Step** soot model.

Equivalence Ratio Exponent
is the exponent r in Equation 14.128 in the Theory Guide. This item appears only for the **One-Step** soot model.

Equivalence Ratio Minimum
and **Equivalence Ratio Maximum** are the minimum and maximum values of the fuel equivalence ratio φ in Equation 14.128 in the Theory Guide. Equation 14.128 will be solved only if **Equivalence Ratio Minimum** $< \varphi <$ **Equivalence Ratio Maximum**; if φ is outside of this range, there is no soot formation. This item appears only for the **One-Step** soot model.

Activation Temperature of Soot Formation Rate
is the term E / R in Equation 14.128 in the Theory Guide. This item appears only for the **One-Step** soot model.

Magnussen Constant for Soot Combustion
is the constant A used in the rate expressions governing the soot combustion rate (Equation 14.130 and Equation 14.131) in the Theory Guide. This item appears only for the **One-Step** and the **Two-Step** soot models. For the **Two-Step** model, this input will be called **Magnussen Constant for Soot and Nuclei Combustion**.

Limiting Nuclei Formation Rate
is the limiting value of the kinetic nuclei formation rate η_0 in Equation 14.137 in the Theory Guide. Below this limiting value, the branching and termination term, $(f-g)$ in Equation 14.136 in the Theory Guide, is not included. This item appears only for the **Two-Step** soot model.

Nuclei Branching-Termination Coefficient
is the term $\left(f-g\right)$ in Equation 14.136 in the Theory Guide. This item appears only for the **Two-Step** soot model.

Nuclei Coefficient of Linear Termination on Soot
is the term g_0 in Equation 14.136 in the Theory Guide. This item appears only for the **Two-Step** soot model.

Pre-Exponential Constant of Nuclei Formation
is the pre-exponential term a_0 in the kinetic nuclei formation term, Equation 14.137 in the Theory Guide. This item appears only for the **Two-Step** soot model.

Activation Temperature of Nuclei Formation Rate
is the term E / R in the kinetic nuclei formation term, Equation 14.137 in the Theory Guide. This item appears only for the **Two-Step** soot model.

Alpha for Soot Formation Rate
is α, the constant in the soot formation rate equation, Equation 14.134 **Two-Step** soot model.

Beta for Soot Formation Rate
is β, the constant in the soot formation rate equation, Equation 14.134 in the Theory Guide. This item appears only for the **Two-Step** soot model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Magnussen Constant for Soot and Nuclei Combustion
is the constant A used in the rate expressions governing the soot combustion rate (Equation 14.130 and Equation 14.131 in the Theory Guide). This item appears only for the **One-Step** and the **Two-Step** soot models.

[OH] Model
is a drop-down list that allows you to specify the method by which the OH radical concentration is calculated, that is, **instantaneous** or **partial-equilibrium**. This list appears only for the **Moss-Brookes**, **Moss-Brookes-Hall**, and **Method of Moments** soot models.

[O] Model
is a drop-down list that specifies the method by which the O radical concentration is calculated, that is, **equilibrium**, **partial-equilibrium**, or **instantaneous**. This list appears only for the **Moss-Brookes** and the **Moss-Brookes-Hall** soot models, when you have selected **partial-equilibrium** for the **[OH] Model**.

Important

To use the concentration of OH or O predicted by the combustion model, select **instantaneous** for **[OH] Model** or **[O] Model**.

Options
contains an option for modeling the effect of soot on a variable radiation absorption coefficient. This group box will appear only when one of the radiation models in the Radiation Model Dialog Box (p. 2190) is active.

Soot-Radiation Interaction
enables the soot-radiation interaction model described in The Effect of Soot on the Absorption Coefficient in the Theory Guide.

Soot Surface Growth Options
(only for the method of moments soot model) contains an option for modeling the soot surface growth.

Site Density
is the number of sites/cm^2 available on the soot surface for surface growth and oxidation reactions with the method of moment soot model.

Enable Aggregation Model
(only for the method of moments soot model) enables the modeling of soot aggregates.

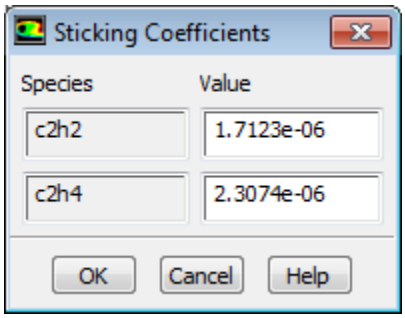
Critical diameter
is the value of the soot particle diameter above which the coagulation regime is switched from coalescent to aggregate.

Fractal dimension
is the parameter that describes the aggregate nature. For soot particles, a value between 1.7 and 2.0 is found to be reasonably good.

37.4.33. Sticking Coefficients Dialog Box

The **Sticking Coefficients** dialog box allows you to set sticking coefficients for the soot model with method of moments. It is opened from the Soot Model Dialog Box (p. 2262). See Setting Up the Method of Moments Soot Model (p. 1196) for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

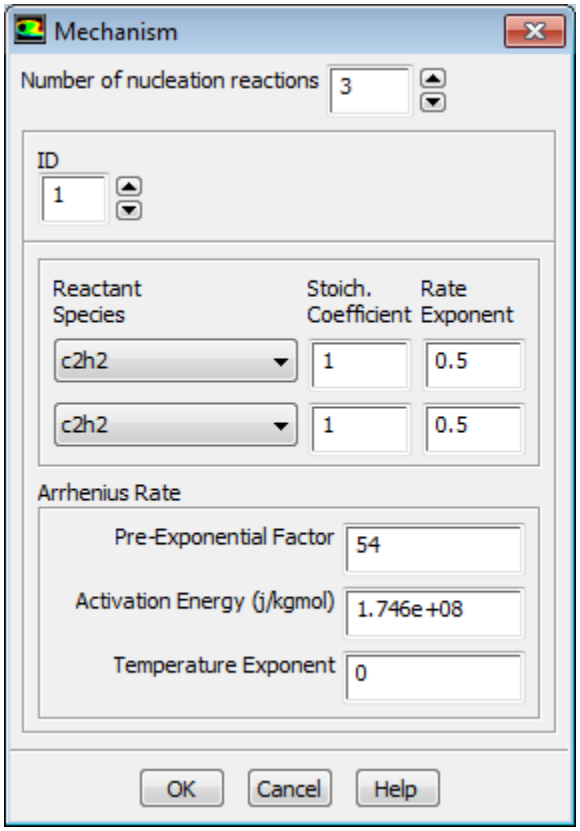


Controls

Species
shows the name of the species for which you specify the **Value**.

37.4.34. Mechanism Dialog Box

The **Mechanism** dialog box allows you to set parameters related to nucleation reactions for the soot model with method of moments. It is opened from the Soot Model Dialog Box (p. 2262). See Setting Up the Method of Moments Soot Model (p. 1196) for details about using this dialog box.



Controls

Number of nucleation reactions
allows you to specify nucleation process as with a single or multi-step reaction mechanism. For each reaction, you must specify all appropriate reaction parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ID
displays the ID of the current nucleation reaction setup.

Reactant Species
is a drop-down list that enables you to select the species for the current nucleation reaction.

Stoich. Coefficient
specifies the stoichiometric coefficient of the reactant species in the nucleation reaction.

Rate Exponent
specifies the rate constant for the reactant species in the current nucleation reaction.

Arrhenius Rate
contains the inputs for the Arrhenius rate parameters related to the current nucleation reaction.

Pre-exponential Factor
is the constant A_r in Equation 7.9 in the Theory Guide. The units of A_r depend on the other rate constant inputs, but must be defined such that the units of the reaction rate $R_{i,r}$ (Equation 7.5 in the Theory Guide) are in (kg/m^3-s) if you are using SI units.

Important

It is important to note that if you have selected the British units system, the Arrhenius factor should still be specified in SI units. This is because ANSYS Fluent applies no conversion factor to the value you enter for A_r (the conversion factor is 1.0) when you work in British units, as the correct conversion factor depends on your values for $\nu_{j,r}$, β_r, and so on.

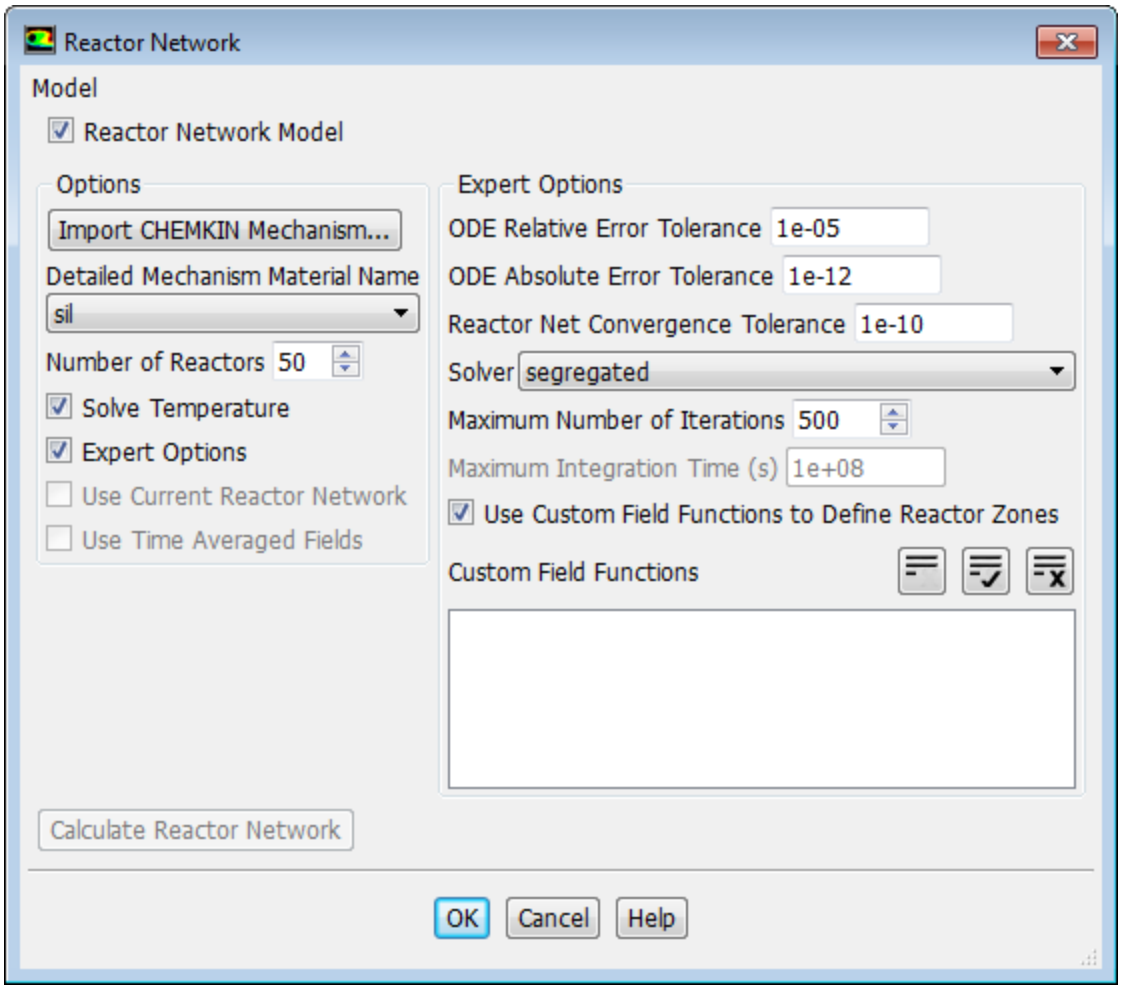
Activation Energy
is the constant E_r in the forward rate constant expression, Equation 7.9 in the Theory Guide).

Temperature Exponent
is the value for the constant β_r in Equation 7.9 in the Theory Guide.

37.4.35. Reactor Network Dialog Box

The **Reactor Network** dialog box allows you to set parameters related to the reactor network model and calculate the reactor network for species transport/combustion. See Reactor Network Model (p. 1020) for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

contains the option for enabling (or disabling) the reactor network model.

Reactor Network Model

enables/disables the modeling of the reactor network.

Options

contains the options for reactor network model. This portion of the dialog box appears only if **Reactor Network Model** is selected.

Import CHEMKIN Mechanism

allows you to import a detailed chemical mechanism in CHEMKIN format.

Detailed Mechanism Material Name

is a drop-down list of available mixture materials from which you can select a mixture material for your reactor network simulation.

Number of Reactors

sets the number of reactors in which cells are grouped based on specified criteria.

Solve Temperature

specifies whether or not the reactor network algorithm solves the temperature. By default, this option is selected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Expert Option
when selected, displays the advanced options related to the solver settings.

Use Current Reactor Network
allows you to perform additional reactor network simulations with the existing network of connected reactors. This option can be enabled once the Fluent solver agglomerates cells and obtains the reactor-network solution.

Use Time Averaged Fields
enables you to select the time-averaged composition fields to be used for clustering reactors and the time-averaged velocity fields for calculating reactor mass flux matrix. This option is available only for unsteady simulations with enabled **Data Sampling For Unsteady Statistics** option.

Expert Options
contains advanced options for ODE solver and for reactor cell clustering control. This portion of the dialog box appears only if **Expert Options** is selected.

ODE Relative Error Tolerance
specifies relative error control for ODE integrator.

ODE Absolute Error Tolerance
specifies absolute error control for ODE integrator.

Reactor Network Convergence Tolerance
allows you to specify tolerance to control the accuracy of the reactor network calculations.

Solver
allows you to select the solver for your simulation. The default segregated solver typically converges faster than the coupled solver. However, if residuals stall above an acceptable tolerance, the coupled solver should be used.

Maximum Number of Iterations
(segregated solver only) sets the maximum number of solver iterations.

Maximum Integration Time
(coupled solver only) sets the maximum elapsed run time for ODE solver. ANSYS Fluent terminates the run at this time if the residuals fail to converge.

Use Custom Field Functions to Define Reactor Zones
enables the use of custom field functions (Custom Field Functions (p. 2003)) for reactor network cell clustering.

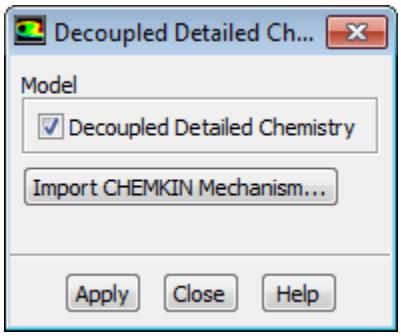
Custom Field Functions
contains the list of available user-defined field functions from which you can select the functions for reactor network cell clustering. This selection list will not appear if the **Use Custom Field Functions to Define Reactor Zones** option is not selected.

Calculate Reactor Network
calculates a chemically reactive flow using reactor network model.

37.4.36. Decoupled Detailed Chemistry Dialog Box

The **Decoupled Detailed Chemistry** dialog box allows you to postprocess slowly-forming, trace pollutant species on a steady-state flow field using detailed chemical kinetic mechanisms.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model
includes the option to enable **Decoupled Detailed Chemistry**.

Import CHEMKIN Mechanism...
opens the CHEMKIN Mechanism Import Dialog Box (p. 2642).

Integration Parameters...
opens the Integration Parameters Dialog Box (p. 2235).

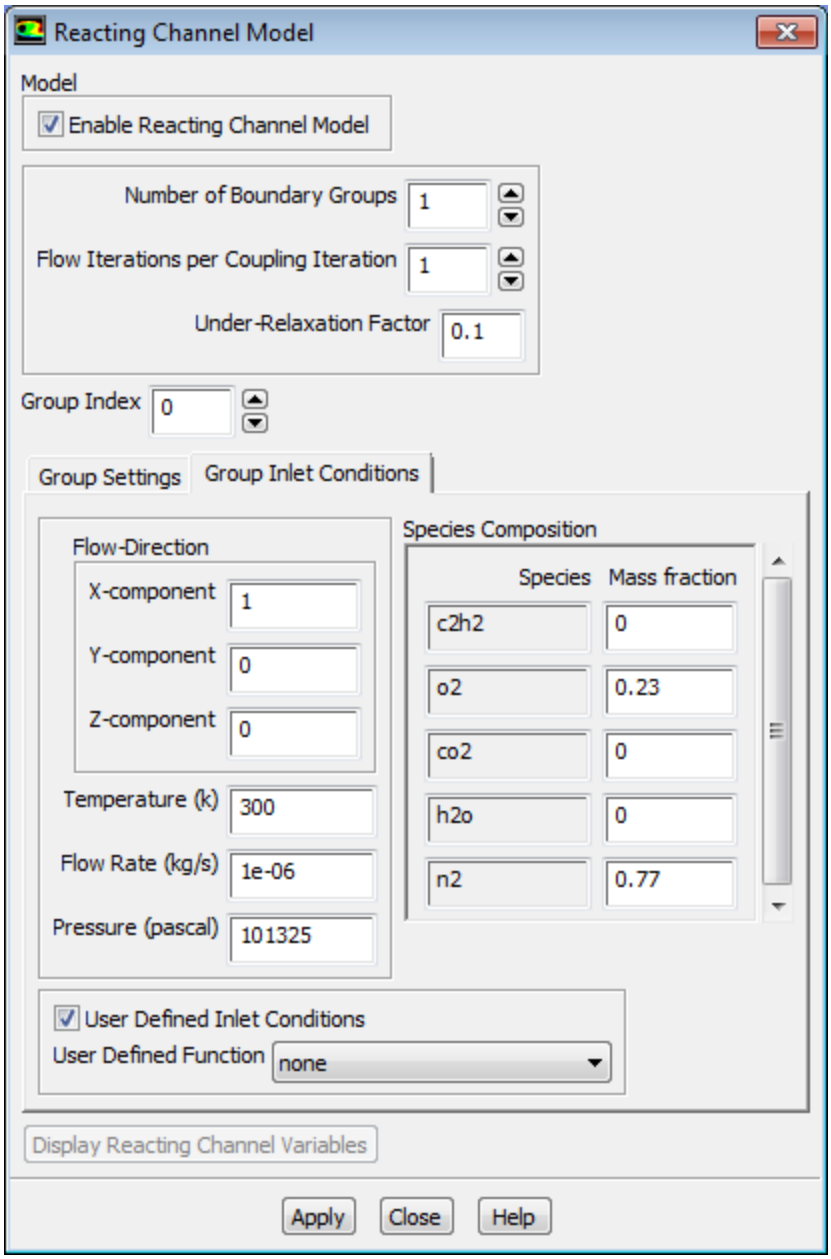
Original Species
are the species that are in the original case setup.

Pollutant Species
are typically slowly forming (far from chemical equilibrium), and occur at miniscule mass fractions.

37.4.37. Reacting Channel Model Dialog Box

The **Reacting Channel Model** dialog box allows you to solve reacting flow in shell and tube heat exchangers with long and thin channels.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model

includes the option to **Enable Reacting Channel Model**.

Number of Boundary Groups

allows you to group together channels with common flow direction, mixture materials, inlet compositions, temperature, pressure, and mass flow rate in cases where you have multiple channels.

Flow Iterations per Coupling Iteration

is the number of outer flow iterations for each channel flow iteration.

Under-Relaxation Factor

is used to update the heat flux from the reacting channel. See Equation 7.107 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Group Index
is used to identify the boundary group.

Group Settings
contains **Group Settings** that you will set.

Channel Walls in Group
are wall boundary zones that correspond to the reacting channels in the group.

Material
is the group material.

Import CHEMKIN Mechanism...
opens the CHEMKIN Mechanism Import Dialog Box (p. 2642).

Model Options
allows you to enable **Surface Reactions** and **Porous Medium** models and set related parameters.

Group Inlet Conditions
is where you specify the **Temperature**, the **Flow Rate**, the **Pressure**, and other inlet conditions of the reacting channel group.

Flow Direction
is the **X-**, **Y-**, and **Z-component** of the flow at the inlets of the channels in the current group.

Species Composition
is where you will specify the inlet mass fractions of the group.

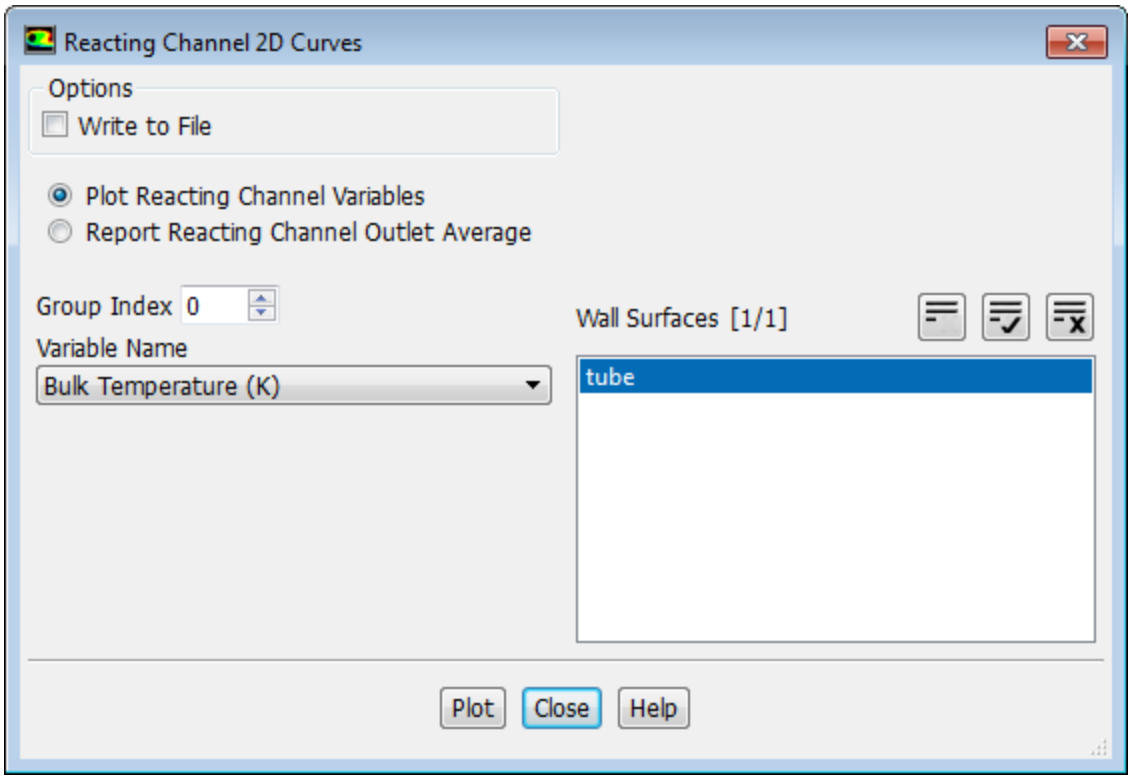
User Defined Inlet Conditions
enables you to hook a user-defined function to specify the reacting channel inlet conditions. When this option is selected, the **User Defined Function** drop-down list becomes visible.

Display Reacting Channel Variables
opens the Reacting Channel 2D Curves Dialog Box (p. 2276) for postprocessing reacting channel variables.

37.4.38. Reacting Channel 2D Curves Dialog Box

The **Reacting Channel 2D Curves** dialog box allows you to display or write 2D curves of the reacting channel.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
gives you the option to **Plot**, **Report**, or **Write to File** channel variables.

Group Index
is used to identify the reacting channel boundary group.

Plot Reacting Channel Variables
enables the plotting of reacting channel variables.

Report Reacting Channel Outlet Average
enables the reporting of reacting channel outlet average.

Variable Name
specifies the channel variable for plotting.

Variable Names
contains a selectable list of channel variables for reporting.

Wall Surfaces
contains a selectable list of wall surfaces on which you can plot, report or write the selected channel variables.

Plot
generates an X-Y plot. The **Plot** button is available when **Plot Reacting Channel Variables** is selected. When the **Write to File** option is enabled, the **Plot** button changes to the **Write...** button.

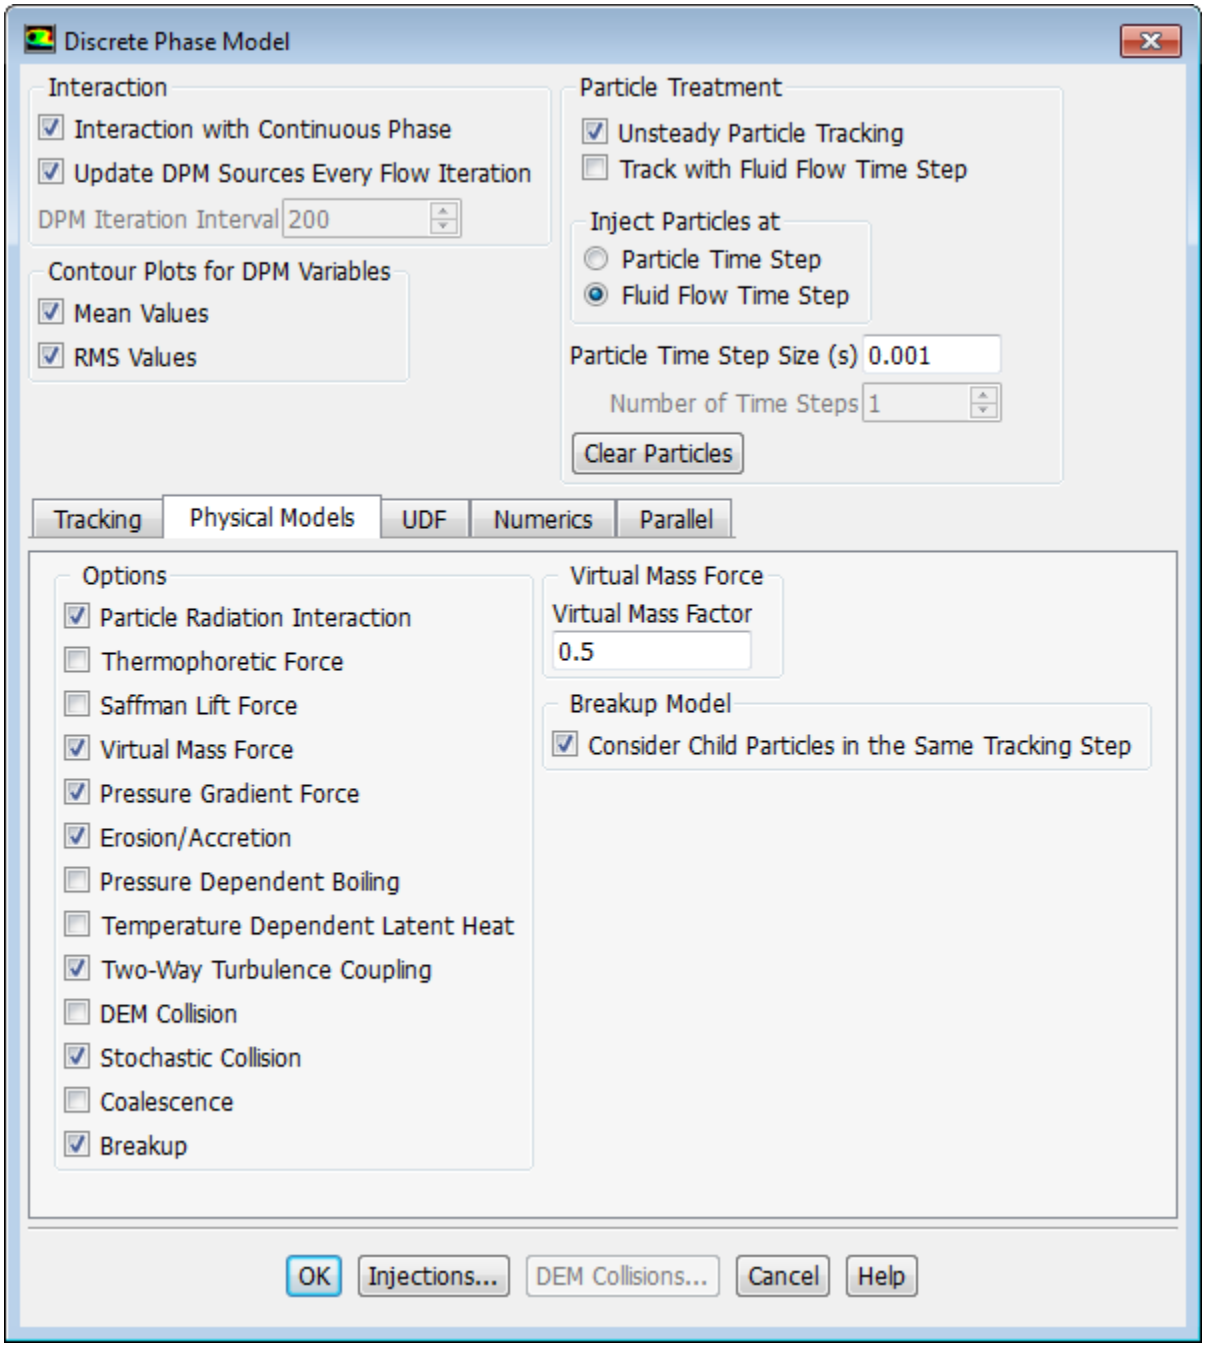
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report

generates the report of the channel variables. The **Report** button is available when **Report Reacting Channel Outlet Average** is selected. When the **Write to File** option is enabled, the **Report** button changes to the **Write...** button.

37.4.39. Discrete Phase Model Dialog Box

The **Discrete Phase Model** dialog box allows you to set parameters related to the calculation of a discrete phase of particles. See Modeling Discrete Phase (p. 1235) for details.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interaction
contains parameters used for performing coupled calculations of the continuous and discrete phase flow. See Procedures for a Coupled Two-Phase Flow (p. 1327) for details.

Interaction with Continuous Phase
enables a coupled calculation of the discrete phase and the continuous phase.

Update DPM Sources Every Flow Iteration
enables calculation of particle source terms at every DPM Iteration. For unsteady simulations, it is the default and is recommended.

DPM Iteration Interval
allows you to control the frequency at which the particles are tracked and the DPM sources are updated.

Contour Plots for DPM Variables
contains options for enabling cell-averaged discrete phase variables for postprocessing.

Mean Values
enables additional cell-averaged discrete phase variables for postprocessing.

RMS Values
enables additional RMS values for several discrete phase variables for postprocessing.

Particle Treatment
contains options for choosing to treat the particles in an unsteady or a steady fashion.

Unsteady Particle Tracking
enables unsteady tracking of particles.

Track with Fluid Flow Time Step
enables the use of fluid flow time steps to inject the particles.

Inject Particles at
contains parameters to decide when to inject the particles for a new time step.

Particle Time Step
enables injection of particles for every particle time step.

Fluid Flow Time Step
enables injection of particles for every fluid flow time step.

In any case, the particles will always be tracked in such a way that they coincide with the flow time of the continuous flow solver, as long as the **Max. Number of Steps** (in the **Tracking** tab) used to compute a single trajectory is sufficient.

Particle Time Step Size
specifies particle time step size for the calculation.

Number of Time Steps
allows you to specify the number of time steps for the calculation.

Clear Particles
clears the particles that are currently in the domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tracking
contains two parameters to control the time integration of the particle trajectory equations.

Tracking Parameters
contains parameters that control the tracking of particle trajectories. For steady-state particle tracking, one simple rule of thumb to follow when setting the two parameters below is that if you want the particles to advance through a domain of length D, the **Length Scale** times the number of **Max. Number of Steps** should be approximately equal to D. See Integration of Particle Equation of Motion in the Theory Guide for details about the items below.

Max. Number of Steps
is the maximum number of time steps used to compute a single particle trajectory via integration of Equation 16.1 in the Theory Guide and Equation 16.58. The default value is 50,000 for steady-state particle tracking and 500 for unsteady particle tracking.

Specify Length Scale
when enabled allows you to specify the length scale.

Length Scale
controls the integration time step size used to integrate the equations of motion for the particle. It appears only when the **Specify Length Scale** option is enabled.

Step Length Factor
specifies the value of λ in Equation 23.3 (p. 1248).

Physical Models
contains optional discrete phase models and their relevant parameters.

Options
contains additional models that can be included in the calculation. See Physical Models for the Discrete Phase Model (p. 1249) for more information.

Particle Radiation Interaction
includes the effect of radiation heat transfer to the particles (Equation 5.34 in the Theory Guide). You will also need to define additional properties for the particle materials (emissivity and scattering factor), as described in Description of the Properties (p. 1317).

This item appears only if the P-1 or discrete ordinates model is selected in the Radiation Model Dialog Box (p. 2190).

Thermophoretic Force
enables the inclusion of a thermophoretic force on the particles as an additional force term. See Thermophoretic Force in the Theory Guide for details.

Saffman Lift Force
enables the inclusion of Saffman's lift force (lift due to shear) as an additional force term. See Saffman's Lift Force in the Theory Guide for details.

Virtual Mass Force

enables the inclusion of virtual mass forces in the particle force balance. See Including the Virtual Mass Force and Pressure Gradient Effects on Particles (p. 1251) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pressure Gradient Force

enables the inclusion of pressure gradient effects in the particle force balance. See Including the Virtual Mass Force and Pressure Gradient Effects on Particles (p. 1251) for details.

Erosion/Accretion

enables the monitoring of erosion/accretion rates at wall boundaries. See Monitoring Erosion/Accretion of Particles at Walls (p. 1251) for details. This item appears only if **Interaction with Continuous Phase** is enabled.

Pressure Dependent Boiling

allows you to switch from droplet vaporization (Law 2) to boiling (Law 3), as described in Enabling Pressure Dependent Boiling (p. 1251).

Temperature Dependent Latent Heat

allows you to include the droplet temperature effects on the latent heat, as described in Equation 16.111 in the Theory Guide.

Two-Way Turbulence Coupling

enables the effect of change in turbulent quantities due to particle damping and turbulence eddies.

DEM Collision

allows you to model DEM collision as described in Modeling Collision Using the DEM Model (p. 1253).

Stochastic Collision

enables the effect of droplet collisions, as described in Collision and Droplet Coalescence Model Theory in the Theory Guide.

Coalescence

enables the effect of droplet coalescence, as described in Collision and Droplet Coalescence Model Theory in the Theory Guide. This option is available when the **Stochastic Collision** option is enabled.

Breakup

enables breakup for all suitable injections. You can select the breakup model and parameters, or disable breakup, for each injection in the Set Injection Properties Dialog Box (p. 2796).

Breakup Model

contains an option to **Consider Child Particles in the Same Tracking Step**. This control appears only when **Breakup** is enabled under **Options**.

DEM Collision Model

contains model settings that allow you to continue your setup of the model.

Adaptive Collision Mesh Width

is enabled by default. This adjusts the width of the collision mesh to the largest parcel diameter multiplied by the **Edge Scale Factor**

Edge Scale Factor

is the factor by which the width of the collision mesh is adjusted to the largest parcel diameter.

Static Collision Mesh Width

is the fixed width of the collision mesh. This appears when the **Adaptive Collision Mesh Width** is disabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum Particle Velocity
limits the maximum particle velocity to a physically plausible range.

DEM Collisions...
opens the DEM Collisions Dialog Box (p. 2285). This button is available at the bottom of the **Discrete Phase Model** dialog box when the **DEM Collision** model is enabled.

UDF
contains parameters that can be used to customize the discrete phase model using a user-defined function. See the separate Fluent Customization Manual for details about user-defined functions.

User-Defined Functions
lists will show available user-defined functions that can be selected to customize the discrete phase model.

Body Force
contains a drop-down list of user-defined functions available for including additional body forces.

Erosion/Accretion
contains a drop-down list of user-defined functions available for incorporating non-standard erosion rate definitions. This item will appear only when the **Erosion/Accretion** option has been enabled.

Scalar Update
contains a drop-down list of user-defined functions available for calculating or integrating scalar values along the particle trajectory.

Source
contains a drop-down list of user-defined functions available for modifying interphase exchange terms.

Spray Collide Function
contains a drop-down list of user-defined functions available for modifying spray collide function.

DPM Timestep
contains a drop-down list of user-defined functions available for modifying DPM time step.

Impingement Model
contains a drop-down list of user-defined functions available for modifying the impingement model. If selected, the **Impingement Model** UDF will overwrite the impingement/splashing model selected for the Lagrangian or Eulerian wall film boundary condition. This item is available only when either **wall-film** is selected for **Boundary Cond. Type** in the **DPM** tab of the **Wall** dialog box or the **Eulerian Wall Film** model is enabled.

Film Regime
contains a drop-down list of user-defined functions available for setting the film regime of particle impingement. This item is available only when either **wall-film** is selected for **Boundary Cond. Type** in the **DPM** tab of the **Wall** dialog box or the **Eulerian Wall Film** model is enabled.

Splashing Distribution
contains a drop-down list of user-defined functions available for modifying distribution of splashed particle variables. If selected, the **Splashing Distribution** UDF will overwrite the impingement/splashing model selected for the Lagrangian or Eulerian wall film boundary condition. This item is available only when either **wall-film** is selected for **Boundary Cond. Type** in the **DPM** tab of the **Wall** dialog box or the **Eulerian Wall Film** model is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Variables
lists the user input variables.

Number of Scalars
sets the number of scalar values used in the calculations with user-defined functions.

Numerics
tab gives you control over the numerical schemes for particle tracking as well as solutions of heat and mass equations. See Numerics of the Discrete Phase Model (p. 1260) for details.

Tracking Options
contains parameters of solutions of heat and mass equations.

Accuracy Control
enables the solution of equations of motion within a specified tolerance.

Tolerance
is the maximum relative error that has to be achieved by the tracking procedure.

Max. Refinements
is the maximum number of step size refinements in one single integration step. If this number is exceeded the integration will be conducted with the last refined integration step size.

Track in Absolute Frame
enables tracking the particles in the absolute reference frame.

Tracking Scheme Selection
contains parameters for selection of numerical schemes.

Automated
enables a mechanism to switch in an automated fashion between numerically stable lower order schemes and higher order schemes, which are stable only in a limited range.

High Order Scheme
can be chosen from the group consisting of **trapezoidal** and **runge-kutta** scheme.

Low Order Scheme
consists of **implicit** and the exponential **analytic** integration scheme.

Tracking Scheme
allows you to choose any of the tracking schemes. You also can combine each of the tracking schemes with Accuracy Control. It is selectable only if **Automated** is switched off.

Coupled Heat-Mass Solution
enables the solution of the corresponding equations using a coupled ODE solver with error tolerance control for the **Droplet**, **Combusting**, or **Multicomponent** particles. See Including Coupled Heat-Mass Solution Effects on the Particles (p. 1262) for details.

Vaporizing Limiting Factors
for the **Mass** and **Heat** are set at the default values of 0.3 and 0.1, respectively. See Including Coupled Heat-Mass Solution Effects on the Particles (p. 1262) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Averaging

contains settings for node based averaging of DPM quantities. See Node Based Averaging of Particle Data (p. 1263) for details.

Enable Node Based Averaging
enables node based averaging and displays additional related options.

Average DPM Source Terms
enables averaging of source terms for the discrete phase.

Average in Each Integration Time Step
enables averages during each integration time step.

Average DDPM Variables
enables averaging of DDPM variables when the DDPM model is active.

Kernel Settings

contains settings for the kernel used by the node based averaging algorithm.

Averaging Kernel
selects the kernel to use for averaging

Gaussian Factor
sets the constant for the Gaussian distribution when **gaussian** is selected for **Averaging Kernel**.

Source Terms

Linearize Source Terms
enables the linearization of source terms for the discrete phase.

Parallel
contains parameters that control the compute nodes for performing discrete phase calculations in parallel. See Parallel Processing for the Discrete Phase Model (p. 1360) for details.

Methods
allows you to select the mode for parallel processing. This group box is editable only for the parallel version of ANSYS Fluent; for the serial version, the **Shared Memory** option (see the description that follows) is selected by default.

Message Passing
enables cluster computing and also works on shared-memory machines. With this option, the compute node processes themselves perform the particle work on their local partitions and particle migration to other compute nodes is implemented using message passing primitives. No special requirements are placed on the host machine. Note that this model is not available if the **Cloud Model** option is enabled in the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box. The **Message Passing** option is irrelevant for the serial ANSYS Fluent code while the **Shared Memory** option remains valid.

Shared Memory
allows you to specify parameters for performing the calculations on shared-memory multiprocessor machines.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Hybrid
allows you to combine **Message Passing** (as previously described) and **OpenMP** for a dynamic load balancing without migration of cells. This option enables multicore cluster computing, and also works on shared-memory machines. When using the **Hybrid** option, you can control the maximum number of threads on each machine via the **Thread Control** dialog box (see Controlling the Threads (p. 2058) for details). Note that this option is not available if the **Cloud Model** option is enabled in the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box.

Shared Memory Options
contains settings for the **Shared Memory** option. This group box is only available if **Shared Memory** is selected from the **Methods** list.

Workpile Algorithm
specifies that the discrete phase calculations are to be performed on a shared-memory multiprocessor machine.

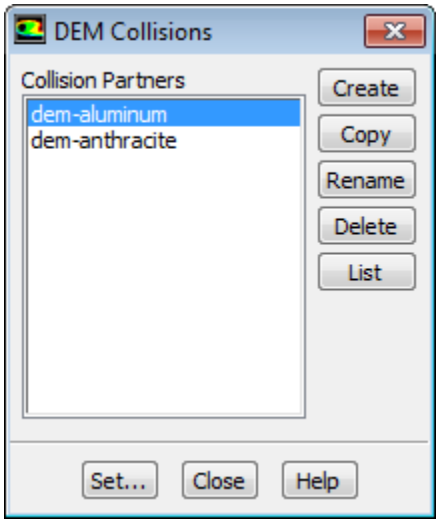
Number of Threads
specifies the number of threads to be used in performing the particle calculations. By default, this parameter is equal to the number of compute nodes you specified for the parallel solver. (This item appears only if **Workpile Algorithm** is enabled.)

Hybrid Options
contains settings for the **Hybrid** option. This group box is only available if **Hybrid** is selected from the **Methods** list.

Use DPM Domain
enables the use of a separate computational domain for particle tracking, which improves load balancing and scalability at the expense of some additional memory overhead.

37.4.40. DEM Collisions Dialog Box

The **DEM Collisions** dialog box allows you to manage the collision partners.



Controls

Collision Partners
contains a list from which you can select one or more collision partners in order to set, create, copy, rename, delete, or list.

Create
creates a new collision partner and opens the Create Collision Partner Dialog Box (p. 2286), in which you can enter the collision partner name.

Copy
creates a new injection with the same properties as the selected collision partner and opens the Copy Collision Partner Dialog Box (p. 2286).

Rename
allows you to change the name of the collision partner. It opens the Copy Collision Partner Dialog Box (p. 2286).

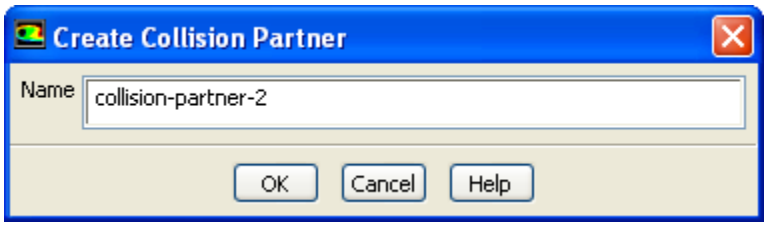
Delete
deletes the collision partner selected in the **Collision Partners** list.

List
lists the collision partners with their corresponding laws.

Set...
opens the DEM Collision Settings Dialog Box (p. 2287) for the collision partner selected in the **Collision Partners** list.

37.4.41. Create Collision Partner Dialog Box

The **Create Collision Partner** dialog box allows you to specify the name of the collision partner.

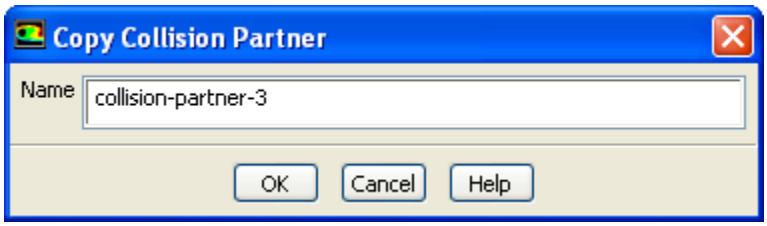


Controls

Name
is the name of the collision partner being created.

37.4.42. Copy Collision Partner Dialog Box

The **Copy Collision Partner** dialog box allows you to copy the selected collision partner.



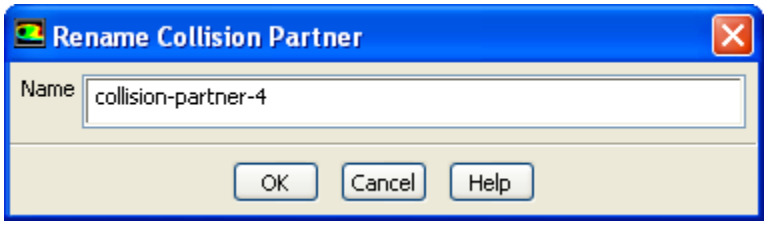
Controls

Name
is the name of the new collision partner copied from the selected partner.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.4.43. Rename Collision Partner Dialog Box

The **Rename Collision Partner** dialog box allows you to rename the selected collision partner.

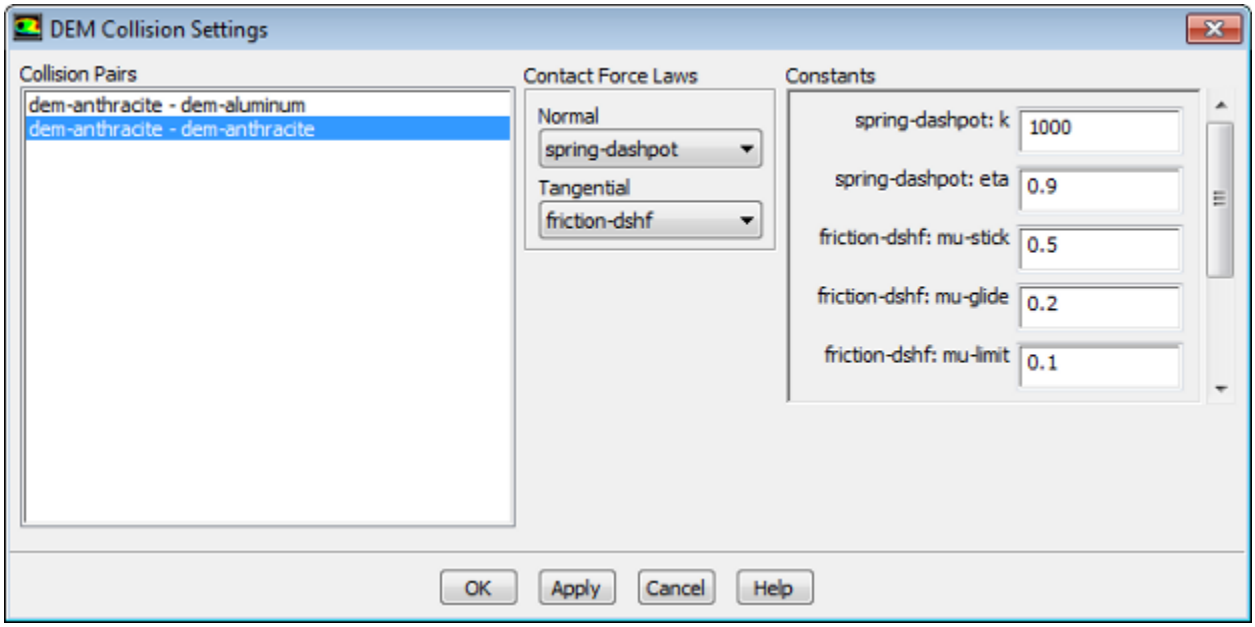


Controls

Name
is the new name of the collision partner selected in the list.

37.4.44. DEM Collision Settings Dialog Box

The **DEM Collision Settings** dialog box allows you to specify the collision laws of the collision partners.



Controls

Collision Pair
contains the list of created collision partners.

Contact Force Laws
is where you will define the collisions laws.

Normal
allows you to choose between **spring**, **spring-dashpot**, **hertzian**, and **hertzian-dashpot**. You can also choose **none** if you do not want to include a contact force.

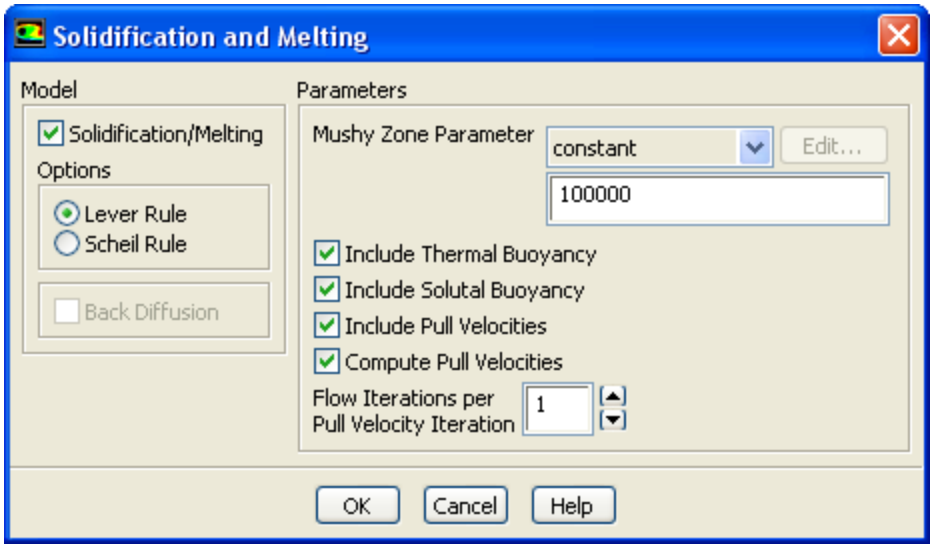
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tangential
allows you to choose between the **friction-dhsf** and **friction-dshf-rolling** force laws. You can also exclude a force law, in which case you would select **none**.

Constants
contains the list of contact force constants. Depending on the contact force law in effect, different constants will be visible.

37.4.45. Solidification and Melting Dialog Box

The **Solidification and Melting** dialog box allows you to set parameters related to the solidification/melting model. See Modeling Solidification and Melting (p. 1527) for details about the items below.



Controls

Model
contains the option for turning on the model.

Solidification/Melting
enables/disables the modeling of solidification and/or melting.

Options
gives you the option of selecting one of two model rules.

Lever Rule
allows you to use the Lever rule (Equation 18.14 in the Theory Guide).

Scheil Rule
allows you to use the Scheil rule (Equation 18.18 in the Theory Guide). If you select **Scheil Rule**, then you can enable **Back Diffusion**. Enter either a **constant** or a user-defined function to specify the value of the **Back Diffusion Parameter**, used in Equation 18.19 to Equation 18.21 in the Theory Guide. Refer to `DEFINE_SOLIDIFICATION_PARAMS` of the Fluent Customization Manual for detailed information about the user-defined function.

Parameters
contains parameters related to the solidification/melting model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mushy Zone Constant
sets the value of A_{mush} in Equation 18.6 in the Theory Guide.

Include Thermal Buoyancy
includes the gravitational force due to the variation of density with temperature. Refer to Thermal and Solutal Buoyancy in the Theory Guide for more information.

> **Note**
>
> This option is available only when solidification is modeled with species transport.

Include Solutal Buoyancy
includes the gravitational force due to the variation of density with the change in the species composition of the melt. Refer to Thermal and Solutal Buoyancy in the Theory Guide for more information.

> **Note**
>
> This option is available only when solidification is modeled with species transport.

Include Pull Velocities
includes pull velocities in the model, as described in Momentum Equations and Pull Velocity for Continuous Casting in the Theory Guide.

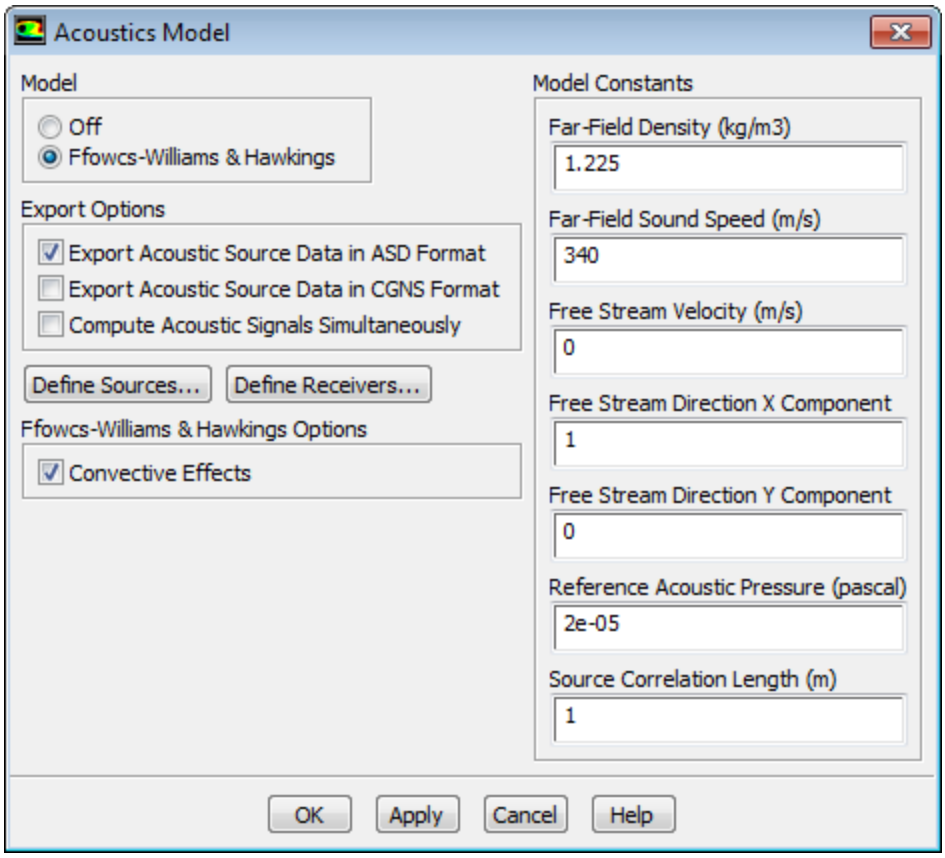
Compute Pull Velocities
enables the calculation of pull velocities based on the specified velocity boundary conditions, as described in Pull Velocity for Continuous Casting in the Theory Guide. This option appears when **Include Pull Velocities** is turned on.

Flow Iterations per Pull Velocity Iteration
specifies the number of times the pull velocity equations will be solved after each iteration of the solver. This option appears when **Compute Pull Velocities** is turned on.

37.4.46. Acoustics Model Dialog Box

The **Acoustics Models** dialog box allows you to set parameters related to the acoustics model. See Using the Ffowcs-Williams and Hawkings Acoustics Model (p. 1207) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Model
contains the option for turning on the acoustics model.

Off
disables the acoustics model.

Ffowcs-Williams & Hawkings
enables the Ffowcs Williams and Hawkings (FW-H) acoustics model. See Postprocessing the FW-H Acoustics Model Data (p. 1219) for details.

Broadband Noise Sources
enables the broadband noise acoustics model. See Using the Broadband Noise Source Models (p. 1231) for details.

Export Options
contains the parameters related to **Ffowcs-Williams & Hawkings** model.

Export Acoustic Source Data in ASD Format
enables/disables the saving of source data files in ASD format.

Export Acoustic Source Data in CGNS Format
enables/disables the saving of source data files in CGNS format.

Compute Acoustics Signals Simultaneously
enables "on-the-fly" calculation of sound. When this option is chosen, the ANSYS Fluent console window will print a message at the end of each time step indicating that the sound pressure signals have been

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

computed (for example, `Extracting sound signals at x receiver locations...`, where `x` is the number of receivers you specified). Enabling this option instructs ANSYS Fluent to compute sound pressure signals at the end of each time step, which will slightly increase the computation time.

Ffowcs-Williams & Hawkings Options
contains the **Convective Effects** option, which should be enabled for all cases dealing with external flows around bodies. When this option is enabled, you will need to specify the proper **Free Stream Velocity** and **Free Stream Direction**.

Define Sources...
opens the Acoustic Sources Dialog Box (p. 2292), which allows you to specify the acoustics sources.

Define Receivers...
opens the Acoustic Receivers Dialog Box (p. 2293), which allows you to specify the location of the receivers.

Model Constants
contains parameters related to the acoustics model.

Far-Field Density
sets the value of the far-field fluid density (ρ_0 in Equation 15.1 in the Theory Guide).

Far-Field Sound Speed
sets the speed of the sound at the far-field (a_0 in Equation 15.5 and Equation 15.6 in the Theory Guide).

Free Stream Velocity
is available when the **Convective Effects** option for the **Ffowcs-Williams & Hawkings** model is enabled.

Free Stream Direction
is available when the **Convective Effects** option for the **Ffowcs-Williams & Hawkings** model is enabled.

Reference Acoustic Pressure
is used to calculate the sound pressure level in dB.

Reference Acoustic Power

is used to non-dimensionalize the acoustic power, giving the sound pressure level in dB (see Fast Fourier Transform (FFT) Postprocessing (p. 1873)). This parameter is equal to 4×10^{-10} W for airborne sound and 10^{-12} W for underwater sound.

Reference Acoustic Intensity

is defined as $P_{ref}^2 / \left(\rho_0 a_0\right)$, although this quantity is not currently used by ANSYS Fluent.

Source Correlation Length
is required when sound is to be computed using a 2D flow result. The FW-H integrals will be evaluated over this length in the depthwise direction using the identical source data.

Number of Realizations
is the number of times the noise source terms will be computed through the generation of stochastic turbulent velocity field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Number of Fourier Modes
is the number of terms in the Fourier summation from which the turbulent velocity field and its derivatives are computed.

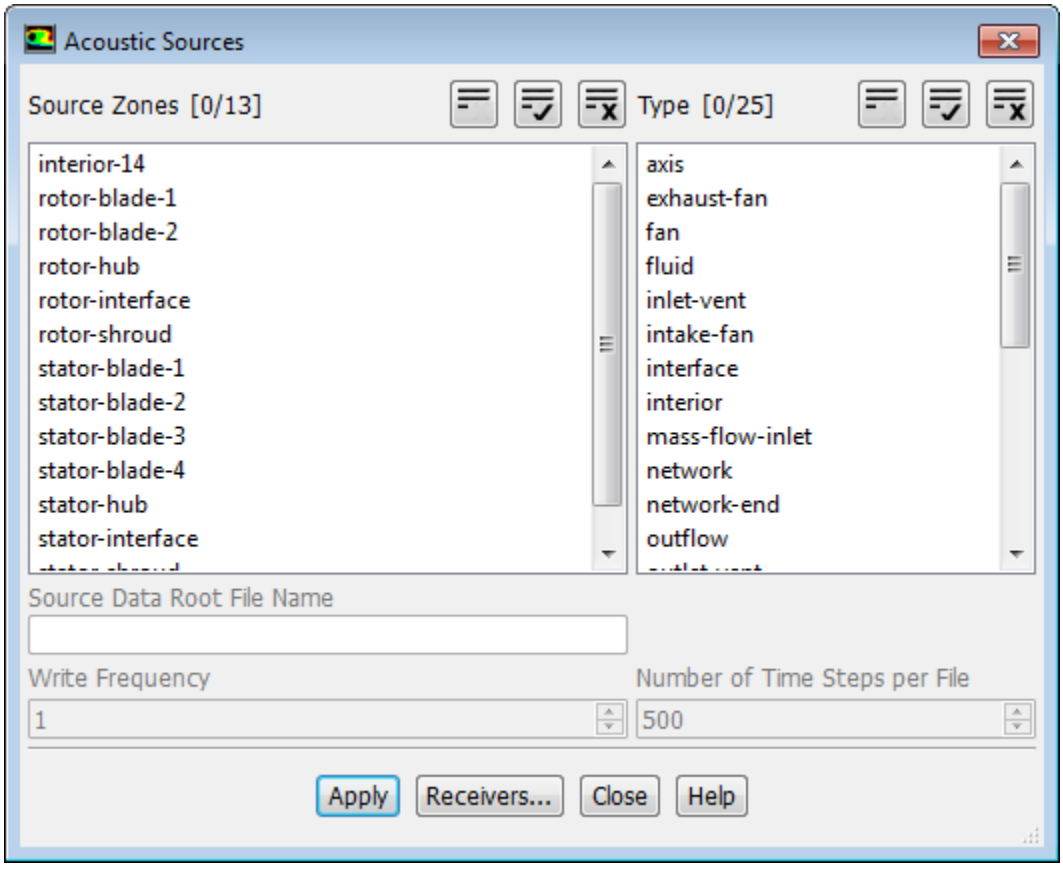
Number of Time Steps Per Revolution
is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of equivalent time steps that it will take for the rotating zone to complete one revolution.

Number of Revolutions
is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of revolutions that will be simulated in the model.

Apply
saves the acoustics model settings.

37.4.47. Acoustic Sources Dialog Box

The **Acoustic Sources** dialog box allows you to specify the acoustics sources. See Using the Ffowcs-Williams and Hawkings Acoustics Model (p. 1207) for details about the items below.



Controls

Source Zones
contains a list of zones from which you can select one or more emission (source) surfaces.

Type
contains a list of all possible types of zones from which you can select one or more types of the available zones. If you select an available type of zone, the relevant zones will then be selected in the **Source Zones**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

list. If you specify any valid **interior** zones as source surfaces, the Interior Cell Zone Selection Dialog Box (p. 2294) will appear.

Source Data Root File Name
is used to give the names of the source data files (for example, `acoustic_example_xxxx.asd`, where `xxxx` is the global time-step index of the transient solution) and an index file (for example, `acoustic_example.index`) that will store the information associated with the source data.

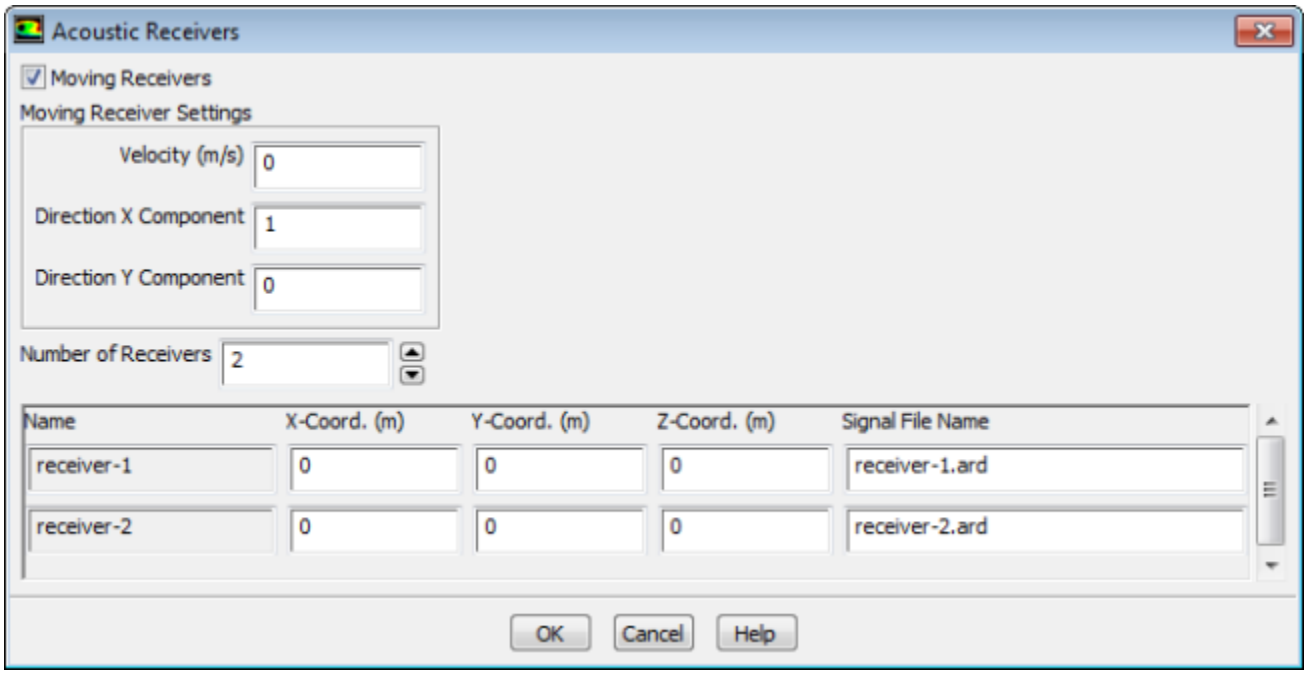
Write Frequency
allows you to control how often the source data will be written. This will enable you to save disk space if the time-step size used in the transient flow simulation is smaller than necessary to resolve the sound frequency you are attempting to predict.

Number of Time Steps per File
allows you to write the source data to multiple files, each containing the source data for a number of time steps specified by you.

Receivers...
opens the Acoustic Receivers Dialog Box (p. 2293), which allows you to specify the location of the receivers.

37.4.48. Acoustic Receivers Dialog Box

The **Acoustic Receivers** dialog box allows you to specify the location of the acoustic receivers. See Using the Ffowcs-Williams and Hawkings Acoustics Model (p. 1207) for details about the items below.



Controls

Moving Receivers
allows you to specify the locations of the moving receivers.

Moving Receiver Settings
allows you to specify the **Velocity** and the **Direction** of the moving receivers.

Number of Receivers
allows you to specify the total number of receivers for which you want to compute sound.

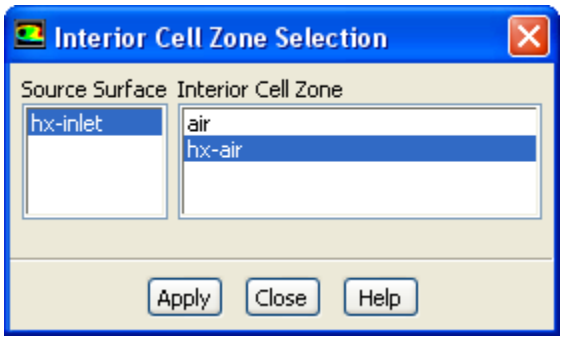
Name
shows the name of the receiver. If you edit the field, the new name will take effect after you click the **OK** button.

X-Coord., Y-Coord., Z-Coord.
specifies the coordinates for each receiver. Note that because ANSYS Fluent's acoustics model is ideally suited for far-field noise prediction, the receiver locations you define should be at a reasonable distance from the sources of sound (that is, the selected acoustic surface), and can fall outside of the computational domain if needed.

Signal File Name
specifies the name of the file used to store sound pressure signals for the corresponding receivers. By default, the files will be named `receiver-1.dat`, `receiver-2.dat`, and so on.

37.4.49. Interior Cell Zone Selection Dialog Box

The **Interior Cell Zone Selection** dialog box allows you to specify the acoustics sources. See Specifying Source Surfaces (p. 1214) for details about the items below.



Controls

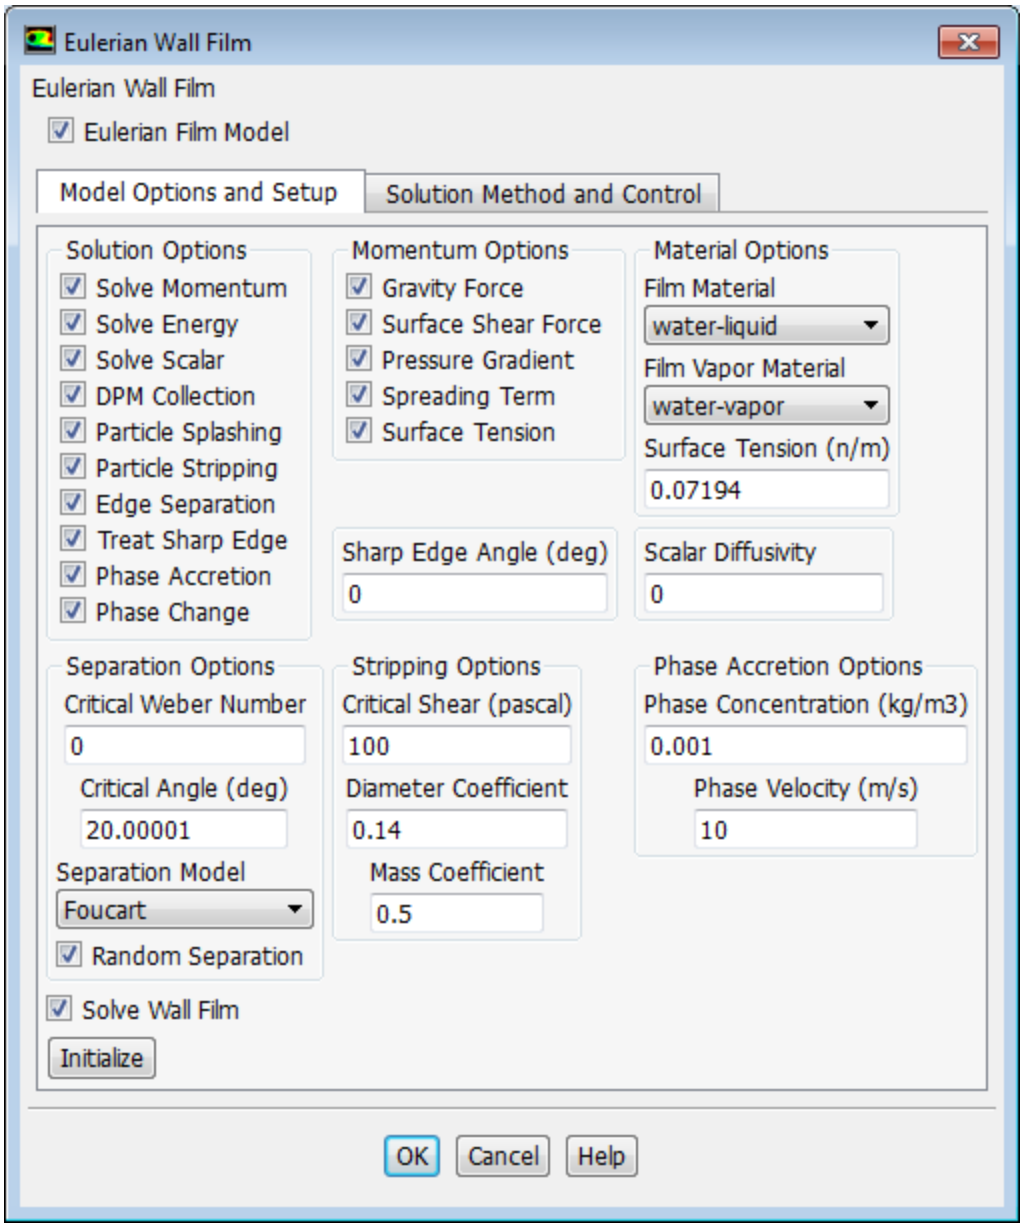
Source Surface
displays the selected interior surface.

Interior Cell Zone
contains a list of two interior cell zones, from which you will select the zone that is occupied by the quadrupole sources.

37.4.50. Eulerian Wall Film Dialog Box

The **Eulerian Wall Film** dialog box allows you to set various model and solution method controls for the Eulerian Wall Film model. For more information, see Modeling Eulerian Wall Films (p. 1535).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Eulerian Wall Film

enables/disables the use of the Eulerian Wall Film model in the calculations.

Model Options and Setup

contains controls for specific solution, discrete phase model (DPM), and material options for the Eulerian Wall Film model.

Solution Options

includes options for enabling/disabling the momentum equation and DPM calculations.

Solve Momentum

allows the momentum equation (see Equation 19.2 in the *Fluent Theory Guide*) to be solved.

Solve Energy

allows the energy equation (see Equation 19.3 in the *Fluent Theory Guide*) to be solved.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solve Scalar
allows the passive scalar equation (see Equation 19.36 in the *Fluent Theory Guide*) to be solved. Once you enable this option, you can set **Scalar Diffusivity**.

DPM Collection
allows for the effect of discrete particle streams or discrete particles hitting a face on a wall boundary that are then absorbed into the film. Once enabled, the **Particle Splashing**, **Particle Stripping**, and **Edge Separation** options become available (see DPM Collection in the Theory Guide). In addition, you can also set **Impingement Parameters** in the Wall Dialog Box (p. 2456).

Particle Splashing
(available when **DPM Collection** is enabled) enables particle splashing globally. You can specify splashing options on selected film wall boundaries in the Wall Dialog Box (p. 2456).

Particle Stripping
(available when **DPM Collection** is enabled) allows you to set the **Critical Shear**, **Diameter Coefficient**, and **Mass Coefficient**, available under **Stripping Options**.

Edge Separation
(available when **DPM Collection** is enabled) allows you to set the **Critical Weber Number**, **Critical Angle**, and **Separation Model**, available under **Separation Options**.

Treat Sharp Edge
allows you to set the **Sharp Edge Angle** when handling the effects of sharp edges and the wall film.

Phase Accretion
(available when the Eulerian Multiphase or Mixture (with Slip Velocity) model is enabled) allows for the interaction of the wall film with a secondary phase in a multiphase flow. Once enabled, the **Phase Concentration** and **Phase Velocity** can be set under **Phase Accretion Options** (see Secondary Phase Accretion in the Theory Guide).

Phase Change
allows you to account for phase changes between the film material (liquid) and the gas species (vapor). When this option is selected, you can specify the phase change parameters on the selected film wall boundaries in the **Wall Film** tab of the Wall Dialog Box (p. 2456). (See Coupling of Wall Film with Mixture Species Transport in the *Fluent Theory Guide*).

Momentum Options
are available when the **Solve Momentum** option is enabled.

Gravity Force
is the second term on the right hand side of Equation 19.2, and is responsible for accelerating the film in the direction of gravity component that is parallel to the wall.

Surface Shear Force
is the third term on the right hand side of Equation 19.2, and is responsible for accelerating the film in the direction of the external flow.

Pressure Gradient
is the first term on the right hand side of Equation 19.2, and is the term accelerating the film in the direction opposing the gradient in external pressure. For example, if a film on the surface of a wing is being modeled and there is a high pressure region at the leading edge with low pressure on the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

top of the wing, this term will tend to move a uniform film towards the low pressure region on the top of the wing.

Spreading Term
is the P_h term on the right hand side of Equation 19.2, and is responsible for spreading. This term will accelerate the flow in the direction opposing the gradient in height, moving the film towards regions of lower thickness. This term becomes available only when both **Pressure Gradient** and **Gravity Term** are selected.

Surface Tension
is the P_σ term on the right hand side of Equation 19.2. This term becomes available only when **Pressure Gradient** is selected.

Sharp Edge Angle
allows you to account for sharp edges alongside the wall film, when the **Treat Sharp Edge** option is enabled.

Material Options
allows you to apply material properties to the wall film model.

Film Material
is the material assigned to the wall film.

Film Vapor Material
(available only when **Phase Change** is selected) is the material assigned to the wall film vapor.

Surface Tension
is the surface tension for the designated wall film material.

Separation Options
(available when **DPM Collection** and **Edge Separation** are enabled) allows you to set DPM particle separation options (see Film Separation in the Theory Guide).

Critical Weber Number
is the critical value for the Weber number.

Separation Angle
is the critical angle, θ, that separation occurs.

Separation Model
allows you to specify one of three different models to calculate the number and diameter of the shed particle stream at an edge once separation occurs. Available models include: **Foucart** (the default, see Foucart Separation in the Theory Guide), **O'Rourke** (see O'Rourke Separation), and **Friedrich** (see Friedrich Separation).

Random Separation
(available when **DPM Collection** and **Edge Separation** are enabled) allows the random selection of the locations at which the newly spawn particles are injected (due to film separation) along the edge at which the separation takes place.

Stripping Options
(available when **DPM Collection** and **Particle Stripping** are enabled) allows you to set DPM particle stripping options (see Film Stripping in the Theory Guide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Critical Shear
is the critical value of the shear rate on the face where liquid film exists, which, when exceeded, causes mass to be taken from the film.

Diameter Coefficient
is the value of F used in Equation 19.20 in the Theory Guide.

Mass Coefficient
is the value of C used in Equation 19.21 in the Theory Guide.

Splashing Options
(available when **DPM Collection** and **Particle Splashing** are enabled) allows you to set DPM particle splashing options (see Film Sub-Models in the Theory Guide).

Splashed Particles
is the number of splashed discrete particles.

Phase Accretion Options
(available when **Phase Accretion** is enabled) allows you to set secondary phase accretion options (see Secondary Phase Accretion in the Theory Guide).

Phase Concentration
is the value of C_d used in Equation 19.24 in the Theory Guide.

Phase Velocity
is the value of V_d used in Equation 19.24 in the Theory Guide.

Solve Wall Film
allows you to skip the wall film solution during the gas phase solution, but keep the variables and setup active.

Initialize
allows you to initialize the wall film variables and prepare the solver for the solution procedure. The film cannot be solved without first initializing the wall film model.

Solution Method and Control
contains controls for temporal or spatial discretization as well as wall film thickness for the Eulerian Wall Film model.

Discretization
allows you to set the temporal or spatial discretization methods.

Time
allows you to specify the temporal discretization methods. Available options include: **First Order Explicit**, **First Order Implicit**, or **Second Order Implicit**.

Continuity
allows you to specify the spatial discretization methods for continuity. Available options include: **First Order Upwind**, or **Second Order Upwind**.

Momentum
allows you to specify the spatial discretization methods for momentum. Available options include: **First Order Upwind**, or **Second Order Upwind**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Energy
allows you to specify the spatial discretization methods for momentum. Available options include: **First Order Upwind**, or **Second Order Upwind**.

Thickness Control
allows you to specify **Maximum Thickness**.

Time Marching and Time Step Control
allows you to set the number of sub-steps that the film model will take between time steps from the main solver. For example, if the flow time step is 0.001 seconds and the number of time steps is set to 10 in the film model, the film model will take 10 time steps of 0.0001 so that the film time and the flow time match at the end of the solution step. For implicit time stepping, the film model will take 5 additional sub iterations per implicit step, stopping the sub-step when the film residual drops below the value set in the **Sub-Iteration Stop** option.

Adaptive Time Stepping
(steady-state flow) enables the adaptive time stepping method to determine the film time step (Δt) using the maximum Courant number and the initial time step (see Steady Flow in the Theory Guide).

Max. Courant Number
is the maximum value of the Courant number used to compute the film time step.

Initial Time Step
is an initial value for the time step used to compute the film time step.

Time-Step
(steady-state flow; default) is the user-specified size of the time step, Δt (see Steady Flow in the Theory Guide).

Sub-Time Steps
(transient flow) is N_{film} used in Equation 19.50 in the Theory Guide.

Sub-Time Report Interval
(transient flow) specifies the number of iterations between the wall film solution reports.

Sub-Iterations
(available when either **First Order Implicit** or **Second Order Implicit** are enabled for **Time** under **Discretization**) is the number of additional sub iterations per implicit step.

Sub-Iteration Stop
(available when either **First Order Implicit** or **Second Order Implicit** are enabled for **Time** under **Discretization**) is the point at which the sub iterations stop (when the film residual drops below this value).

Sub-Iter Report Interval
(implicit time discretization calculation) specifies the number of sub-iterations between the wall film solution reports.

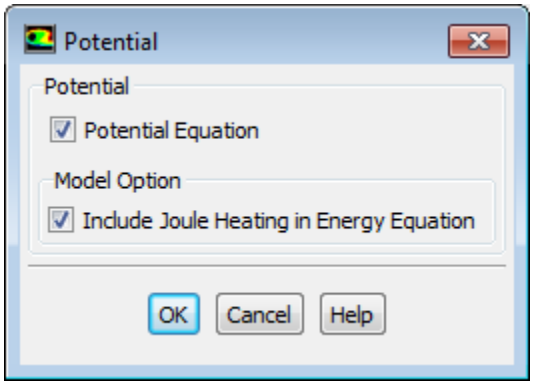
DPM Control
(available when **DPM Collection** is enabled in the **Model Options and Setup** tab) allows you to specify DPM-specific discretization.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Film Steps per DPM step
allows you to set how often the DPM phase is calculated for the film.

37.4.51. Potential Dialog Box

The **Potential** dialog box allows you to set parameters related to the electric potential field in your model. See Using the Electric Potential Model (p. 1547) for details.



Controls

Potential
contains inputs related to modeling of the electric potential field.

Potential Equation
enables/disables the simulation of the electric potential field in the model.

Model Option
allows you to enable/disable the **Include Joule Heating in Energy Equation** option. This option appears only if the energy equation is enabled.

37.5. Materials Task Page

The **Materials** task page allows you to set properties for any fluid or solid (or mixture, if applicable) materials in your ANSYS Fluent simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Materials
contains a listing of available fluid or solid (or mixture, if applicable) materials.

Create/Edit...
displays the Create/Edit Materials Dialog Box (p. 2302) for the selected item in the **Materials** list.

Delete
removes the selected material from the **Materials** list,

37.5.1. Create/Edit Materials Dialog Box

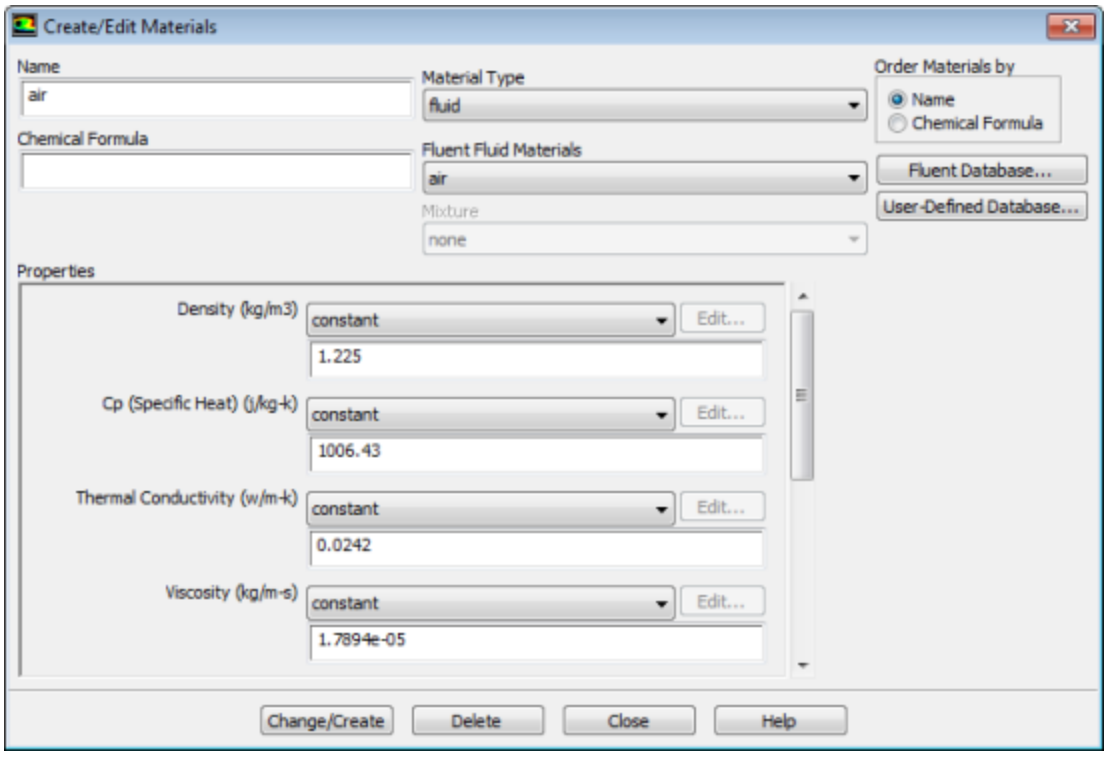
The **Create/Edit Materials** dialog box is used to create and modify materials. Materials can be downloaded from the global database or defined locally. See Physical Properties (p. 459) for details about defining material properties. Using the **Create/Edit Materials** Dialog Box (p. 461) describes how to use the dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name

shows the name of the material. If you edit this field, the new name will take effect when you click **Change/Create**.

Chemical Formula

displays the chemical formula for the material. You should generally not edit this field unless you are creating a material from scratch.

Material Type

is a drop-down list containing all of the available material types. By default, **fluid** and **solid** will be the only choices. If you are modeling species transport/combustion, **mixture** will also be available. For problems in which you have defined discrete-phase injections, **inert-particle**, **droplet-particle**, and/or **combusting-particle** will also appear.

Fluent Fluid Materials

allows you to choose the fluid material for which you want to modify properties. This option is available when **fluid** is selected in the **Material Type** drop-down list.

Fluent Solid Materials

allows you to choose the solid material for which you want to modify properties. This option is available when **solid** is selected in the **Material Type** drop-down list.

Fluent Mixture Materials

allows you to choose the mixture material for which you want to modify properties. This option is available when **mixture** is selected in the **Material Type** drop-down list.

Fluent Droplet Particle Materials

allows you to choose the droplet-particle for which you want to modify properties. This option is available when **droplet-particle** is selected in the **Material Type** drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Order Materials by
allows you to order the materials in the **Materials** list alphabetically by **Name** or alphabetically by **Chemical Formula**.

Fluent Database...
opens the Fluent Database Materials Dialog Box (p. 2312), from where you can copy materials from the global database into the current solver.

User-Defined Database...
opens the Open Database Dialog Box (p. 2313), where you can specify the user-defined database to be used.

Properties
contains input fields for the material properties that are required for the active physical models.

Density
sets the material density. You may set a constant value, or select one of the other methods from the drop-down list above the real number field. See Density (p. 479) for instructions on setting density.

Cp (Specific Heat)
sets the constant-pressure specific heat of the material. You may set a constant value, or select one of the other methods from the drop-down list above the real number field. See Specific Heat Capacity (p. 513) for instructions on setting specific heat.

Thermal Conductivity
sets the thermal conductivity of the material. You may set a constant value, or select one of the other methods from the drop-down list above the real number field. See Thermal Conductivity (p. 497) for instructions on setting thermal conductivity.

Viscosity
sets the viscosity of the material. You may set a constant value, or select one of the other methods from the drop-down list above the real number field. See Viscosity (p. 487) for instructions on setting viscosity.

Molecular Weight
sets the molecular weight of the material. It is used to derive the gas constant of the material.

Standard State Enthalpy
specifies the formation enthalpy of a fluid material for a reacting flow. See Standard State Enthalpies (p. 528) for details.

Standard State Entropy
specifies the standard state entropy of a fluid material for a reacting flow. This input is used only if the fluid material is involved in a reversible reaction. See Standard State Entropies (p. 528) for details.

Reference Temperature
specifies the reference temperature for the **Heat of Formation**.

L-J Characteristic Length
specifies the kinetic theory parameter σ for a fluid material. See Kinetic Theory Parameters (p. 529) for details.

L-J Energy Parameter
specifies the kinetic theory parameter ε / k for a fluid material. See Kinetic Theory Parameters (p. 529) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Absorption Coefficient

specifies the absorption coefficient a for radiation heat transfer. See Radiation Properties (p. 515) for details. If you choose the **wsggm-user-specified** option from the drop-down list next to **Absorption Coefficient**, the WSGGM User Specified Dialog Box (p. 2348) will open. If you choose the **user-defined-wsggm** option from the drop-down list next to **Absorption Coefficient**, the User-Defined Functions Dialog Box (p. 2321) will open.

Scattering Coefficient

specifies the scattering coefficient σ_s for radiation heat transfer (only for the P-1, Rosseland, DO, or MC radiation models). See Radiation Properties (p. 515) for details.

Scattering Phase Function

specifies an **isotropic** (by default) or **linear-anisotropic** scattering function. If you are using the DO model, **delta-eddington** and **user-defined** scattering functions are also available. See Radiation Properties (p. 515) for details. If you choose **delta-eddington**, the Delta-Eddington Scattering Function Dialog Box (p. 2349) will open.

Refractive Index

specifies the refractive index for the material. It is used only when semi-transparent media are modeled with the DO radiation model.

Mixture Species

specifies the names of the species that comprise a mixture material. To check or modify these names, click the **Edit...** button to open the Species Dialog Box (p. 2332). This property appears only for mixture materials.

Reaction

displays the reaction mechanism being used when you are modeling finite-rate reactions. **finite-rate** appears if **LaminarFinite-Rate** or **Eddy-Dissipation Concept** is selected in the Species Model Dialog Box (p. 2216), **eddy-dissipation** appears if **Eddy-Dissipation** is selected, and **finite-rate/eddy-dissipation** appears if **Finite-Rate/Eddy-Dissipation** is selected.

Click **Edit...** to open the Reactions Dialog Box (p. 2334).

Mechanism

allows you to enable different reactions selectively in different geometrical zones. Click the **Edit** button to open the Reaction Mechanisms Dialog Box (p. 2342). See Defining Zone-Based Reaction Mechanisms (p. 984) for details.

Mass Diffusivity

contains a drop-down list of available methods for specifying the diffusion coefficients for the species in a mixture material. If you select **constant-dilute-appx**, you will enter a constant value in the field below. If you select **dilute-approx** or **multicomponent**, the Mass Diffusion Coefficients Dialog Box (p. 2344) will open, and you can specify the coefficients there. If you select **kinetic-theory**, you will need to specify the kinetic theory parameters for the individual fluid materials (species) that comprise the mixture. See Mass Diffusion Coefficients (p. 519) for details about specifying mass diffusivity.

Thermal Diffusion Coefficient

contains a drop-down list of available methods for specifying the thermal diffusion coefficients for the species in a mixture material. If you select **kinetic-theory**, you will need to specify the kinetic theory materials (species) that comprise the mixture. If you select **specified**, the Thermal Diffusion Coefficients Dialog Box (p. 2346) will open, and you can specify the coefficients there. See Thermal Diffusion Coefficient Inputs (p. 523) for details about specifying thermal diffusion coefficients.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Density of Unburnt Reactants
sets the density (ρ_u in Equation 9.68 in the Theory Guide) of the unburnt products.

Temperature of Unburnt Reactants
sets the temperature (T_u in Equation 9.68 in the Theory Guide) of the unburnt products.

Adiabatic Temperature of Burnt Products
(only for adiabatic premixed combustion models) specifies the value of the burnt products under adiabatic conditions, T_{ad} in Equation 9.65 in the Theory Guide.

Unburnt Thermal Diffusivity
specifies the thermal diffusivity (α in Equation 9.9 in the Theory Guide) for use with the premixed combustion model. See Modeling Premixed Combustion (p. 1089) for details.

Laminar Flame Speed
specifies the value of U_l in Equation 9.9 in the Theory Guide.

Laminar Flame Thickness
specifies the thickness of the flame for which you have a choice of **constant**, **user-defined**, or **diffusivity-over-flame-speed**.

Critical Rate of Strain
specifies the value of g_{cr} in Equation 9.17 in the Theory Guide.

Heat of Combustion
(only for non-adiabatic premixed combustion models) specifies the value of H_{comb} in Equation 9.67 in the Theory Guide.

Unburnt Fuel Mass Fraction
(only for non-adiabatic premixed combustion models) specifies the value of Y_{fuel} in Equation 9.67 in the Theory Guide.

Thermal Expansion Coefficient
specifies the thermal expansion coefficient (β in Equation 12.3 (p. 833)) for use with the Boussinesq approximation. See Steps in Solving Buoyancy-Driven Flow Problems (p. 834) for details.

Droplet Surface Tension
specifies the value of the droplet surface tension (σ in Equation 16.333 in the Theory Guide).

Latent Heat
is the latent heat of vaporization, h_{fg}, required for phase change from an evaporating liquid droplet or for the evolution of volatiles from a combusting particle. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Latent Heat at NBP
is the latent heat of vaporization at the normal boiling point, available for droplet-particles. See Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 548) for details.

Normal Boiling Point (NBP)
is given by Equation 7.117 (p. 549). See Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 548) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thermophoretic Coefficient

specifies the thermophoretic coefficient ($D_{T,p}$ in Equation 16.11 in the Theory Guide), and appears when the thermophoretic force is included in the discrete phase calculation.

Vaporization Temperature

is the temperature, T_{vap}, at which the calculation of vaporization from a liquid droplet or devolatilization from a combusting particle is initiated by ANSYS Fluent. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Boiling Point

is the temperature, T_{bp}, at which the calculation of the boiling rate equation is initiated by ANSYS Fluent. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Vapor-Particle-Equilibrium

is the selected approach for the calculation of the vapor concentration of the components at the surface. This can be Raoult's law (Equation 16.191 in the Theory Guide), the Peng-Robinson real gas model (Equation 16.199 in the Theory Guide), or a user-defined function that provides this value.

Volatile Component Fraction

(f_{v0}) is the fraction of a droplet particle that may vaporize via Laws 2 and/or 3 (Droplet Vaporization (Law 2) in the Theory Guide). For combusting particles, it is the fraction of volatiles that may be evolved via Law 4 (Devolatilization (Law 4) in the Theory Guide). See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Binary Diffusivity

is the mass diffusion coefficient, $D_{i,m}$, used in the vaporization law, Law 2. This input is also used to define the mass diffusion of the oxidizing species to the surface of a combusting particle, $D_{i,m}$. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Diffusivity Reference Pressure

is the reference pressure P_{ref} for the pressure dependent binary diffusivity in Equation 16.110 in the *Fluent Theory Guide*.

Saturation Vapor Pressure

is the saturated vapor pressure, P_{sat}, defined as a function of temperature, which is used in the vaporization law, Law 2. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Heat of Pyrolysis

is the heat of the instantaneous pyrolysis reaction, h_{pyrol}, that the evaporating/boiling species may undergo when released to the continuous phase. The heat of pyrolysis should be entered as a positive number for exothermic reaction and as a negative number for endothermic reaction. The default value of zero implies that the heat of pyrolysis is not considered. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Composition Averaging Coefficient

is the coefficient α_Y in Equation 16.201 in the *Fluent Theory Guide*. To assume bulk gas composition for the physical properties in the particle vaporization and heating rates equations, select `none` from the **Composition Averaging Coefficient** drop-down in the **Create/Edit Materials** dialog box, under **Properties**. To enable property averaging, select `constant` and enter a value between 0 and 1 for

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the **Composition Averaging Coefficient**. $\alpha_Y = 1$ corresponds to bulk gas mixture. For $\alpha_Y = 0$, the composition reverts to the particle surface composition.

Important

When you define the **Composition Averaging Coefficient** with a `constant` value other than 1, you must also specify **Specific Heat**, **Viscosity** and **Thermal Conductivity** for the evaporating species (in the **Create/Edit Materials** dialog box, under **Properties**, for the corresponding fluid material of the continuous phase mixture).

The default and recommended value for the averaging coefficient is 1/3. However, to improve the simulation results, you must provide accurate temperature-dependent data for the vapor material.

Temperature Averaging Coefficient

is the coefficient α_T in Equation 16.200 in the *Fluent Theory Guide*. To assume bulk gas temperature for the physical properties in the particle vaporization and heating rates equations, select `none` from the **Temperature Averaging Coefficient** drop-down in the **Create/Edit Materials** dialog box, under **Properties**. To enable property averaging, select `constant` and enter a value between 0 and 1 for the **Temperature Averaging Coefficient**. $\alpha_T = 1$ corresponds to bulk gas conditions. For $\alpha_T = 0$, the temperature reverts to the particle surface temperature.

Important

When you define the **Temperature Averaging Coefficient** with a `constant` value other than 1, you must also specify **Specific Heat**, **Viscosity** and **Thermal Conductivity** for the evaporating species (in the **Create/Edit Materials** dialog box, under **Properties**, for the corresponding fluid material of the continuous phase mixture).

The default and recommended value for the averaging coefficient is 1/3. However, to improve the simulation results, you must provide accurate temperature-dependent data for the evaporating vapor material.

Vaporization Model

defines which vaporization model is used for pure droplets (Law 2) and for multicomponent droplets (Law 7). If you want to use the default diffusion controlled model, retain the selection of **diffusion-controlled** from the drop-down list to the right of **Vaporization Model**. This will apply Equation 16.101 in the Theory Guide.

To use the convection/diffusion controlled model for vaporization select **convection/diffusion-controlled** from the drop-down list. Equation 16.106 in the Theory Guide will be applied for the calculation of the vaporization rate, and Equation 16.116 in the Theory Guide will be applied in the particle heat transfer calculations This model is recommended when evaporation rates are high. For slowly evaporating droplets both models are expected to give similar results.

If you have selected the **convection/diffusion-controlled**, you can enable the **Variable Lewis Number Formulation** option in Convection/Diffusion Model Dialog Box (p. 2320) to compute the Spalding heat number from Equation 16.115 in the *Fluent Theory Guide*. If the option is disabled ANSYS Fluent uses Equation 16.116.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Degrees of Freedom

specifies the kinetic theory parameter f, which is the number of nodes of energy storage. This parameter is required only if you are defining specific heat via kinetic theory. See Kinetic Theory Parameters (p. 529) for details.

Particle Emissivity

is the emissivity of particles in your model, ε_p, used to compute radiation heat transfer to the particles when the P-1 or DO radiation model is active and particle radiation interaction is enabled in the Discrete Phase Model Dialog Box (p. 2278). See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Particle Scattering Factor

is the scattering factor, f, due to particles in the P-1 or DO radiation model. Note that this property will appear only if particle radiation interaction is enabled in the Discrete Phase Model Dialog Box (p. 2278). See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Swelling Coefficient

is the coefficient, C_{sw}, which governs the swelling of the coal particle during the devolatilization law, Law 4. A swelling coefficient of unity (the default) implies that the coal particle stays at constant diameter during the devolatilization process. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Burnout Stoichiometric Ratio

is the stoichiometric requirement, S_b, for the burnout reaction, in terms of mass of oxidant per mass of char in the particle. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Combustible Fraction

is the mass fraction of char, f_{comb}, in the coal particle (the fraction of the initial combusting particle that will react in the surface reaction) Law 5. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

React. Heat Fraction Absorbed by Solid

is the parameter f_h, which controls the distribution of the heat of reaction between the particle and the continuous phase. The default value of zero implies that the entire heat of reaction is released to the continuous phase. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Heat of Reaction for Burnout

is the heat released by the surface char combustion reaction, Law 5. This parameter is specified in terms of heat release (for example, Joules) per unit mass of char consumed in the surface reaction. See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Devolatilization Model

defines which version of the devolatilization model, Law 4, is being used. If you want to use the default constant rate devolatilization model, retain the selection of **constant** in the drop-down list to the right of **Devolatilization Model** and enter the rate constant A_0 in the field below the list.

Select **single-rate**, **two-competing-rates**, or **cpd-model** in the drop-down list to choose one of the optional devolatilization models (the single kinetic rate model, two kinetic rates model, or CPD model, as described in Devolatilization (Law 4) in the Theory Guide).

When the single kinetic rate model (**single-rate**) is selected, the Single Rate Devolatilization Dialog Box (p. 2350) will appear; when the two competing rates model (**two-competing-rates**) is selected, the Two Competing Rates Model Dialog Box (p. 2351) will appear; and when the CPD model (**cpd-model**) is selected, the CPD Model Dialog Box (p. 2352) will appear.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Combustion Model

defines which version of the surface char combustion law (Law 5) is being used. If you want to use the default diffusion-limited rate model, retain the selection of **diffusion-limited** in the drop-down list. No additional inputs are necessary, because the binary diffusivity defined above will be used in Equation 16.165 in the Theory Guide.

To use the kinetics/diffusion-limited rate model for the surface combustion model, select **kinetics/diffusion-limited** in the drop-down list and enter the parameters in the resulting Kinetics/Diffusion-Limited Combustion Model Dialog Box (p. 2352).

To use the intrinsic model for the surface combustion model, select **intrinsic-model** in the drop-down list and enter the parameters in the resulting Intrinsic Combustion Model Dialog Box (p. 2353).

To use the multiple surface reactions model, select **multiple-surface-reactions** in the drop-down list.

See Setting Material Properties for the Discrete Phase (p. 1313) for details.

Pure Solvent Melting Heat

specifies the latent heat for the melting and solidification model (L in Equation 18.3 in the Theory Guide).

Solidus Temperature

specifies the solidus temperature for the melting and solidification model ($T_{solidus}$ in Equation 18.3 in the Theory Guide). If you are solving for species transport, the solidus temperature is $T_{solidus}$ in Equation 18.8, and you specify the method by which it is calculated: either according to the **mixing-law** (which is based on the parameters of the solutes) or a **user-defined** function.

Liquidus Temperature

specifies the liquidus temperature for the melting and solidification model ($T_{liquidus}$ in Equation 18.3 in the Theory Guide). If you are solving for species transport, the liquidus temperature is T_{liquidus} in Equation 18.9, and you specify the method by which it is calculated: either according to the **mixing-law** (which is based on the parameters of the solutes) or a **user-defined** function.

Pure Solvent Melting Temperature

specifies the melting temperature of pure solvent (T_{melt} in Equation 18.8 and Equation 18.9 in the Theory Guide) for the melting and solidification model when species transport has also been enabled. The solvent is the last species listed under of the mixture material.

Eutectic Temperature

is the lowest alloy melting temperature, which depends on the relative proportions of the mixture composition of the Eutectic species mass fractions.

Slope of Liquidus Line

specifies the slope of the liquidus surface with respect to the concentration of the solute (m_i in Equation 18.8 and Equation 18.9 in the Theory Guide). It is not necessary to specify this value for the solvent. Note that this option is available only for the melting and solidification model when species transport has also been enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Partition Coefficient

specifies the partition coefficient with respect to the concentration of the solute fluid (K_i in Equation 18.8 and Equation 18.9 in the Theory Guide). It is not necessary to specify this value for the solvent. Note that this option is available only for the melting and solidification model when species transport has also been enabled.

Eutectic Mass Fraction

is the mass fraction of a solute in an alloy at which the melting temperature of the alloy is the lowest possible value ($Y_{i,\mathrm{Eut}}$ in Equation 18.10 in the Theory Guide). It is not necessary to specify this value for the solvent. Note that this option is available only for the melting and solidification model when species transport has also been enabled.

Solutal Expansion Coefficient

allows you to specify the coefficient in Equation 18.24 in the Theory Guide for all the species except the last one in the mixture. Note that this option is available only for the melting and solidification model when the **Include Solutal Buoyancy** option is enabled.

Diffusion in Solid

specifies the rate of diffusion in the solid. Note that this option is available only for the melting and solidification model when the Lever rule is selected and the species transport is enabled.

UDS Diffusivity

specifies the diffusion coefficient for a user-defined scalar. This material property is available in the Create/Edit Materials Dialog Box (p. 2302) when you specify one or more user-defined scalars in the User-Defined Scalars Dialog Box (p. 2829). If you select **defined-per-uds**, you will need to specify the diffusion coefficient for each user-defined scalar transport equation in the UDS Diffusion Coefficients Dialog Box (p. 2347).

Electrical Conductivity

sets the material electrical conductivity. You may set a constant value, or select one of the other methods from the drop-down list above the real number field. This material property only becomes available if the electric potential model is enabled.

Charge Number

specifies the charge number for a fluid material for a flow involving electrochemical reactions. The default setting of 0 means that the fluid species is neutral. This material property only becomes available if the electric potential model is enabled.

When you are viewing the database, additional properties may be displayed. However, after you copy the material to the local area, only the properties with relevance to the current problem will be displayed.

Change/Create

changes the properties of a locally stored material or creates a new one in the local area. If no material with the specified **Name** exists locally, ANSYS Fluent will create it. If you have modified the material without changing its name, ANSYS Fluent will simply update the material with your modifications. If you have assigned a new name to the material and a material with this name already exists locally, an error will be indicated; you must then specify a different name or delete the existing material with that name before trying to save the new material.

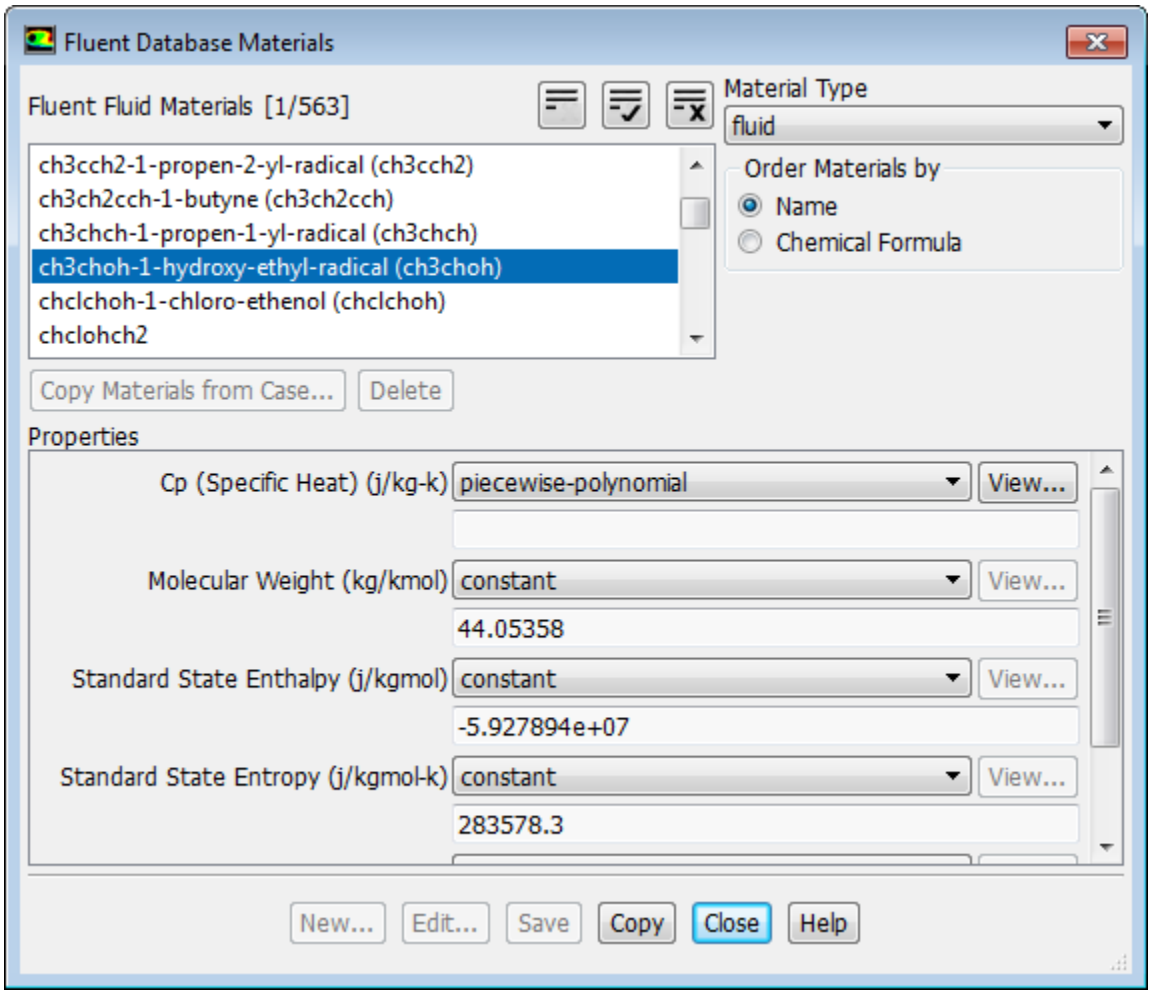
Delete

deletes the currently selected material from the local materials list. It has no effect on the global database.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.2. Fluent Database Materials Dialog Box

The **Fluent Database Materials** dialog box is opened by clicking the **Fluent Database...** button in the Create/Edit Materials Dialog Box (p. 2302). In this dialog box you can view the global (site-wide) material properties database and copy materials list in the solver. See Copying Materials from the ANSYS Fluent Database (p. 464) for details.



Controls

Fluent Fluid Materials

contains a list of all materials of the selected **Material Type** that are defined in the database. The name of this list will change depending on the selected material type (for example, **fluid**, **solid**, and so on). You can select one or more of these materials to be copied to the solver.

Material Type

is a drop-down list containing all of the available material types. By default, **fluid** and **solid** will be the only choices. If you are modeling species transport/combustion, **mixture** will also be available. For problems in which you have defined discrete-phase injections, **inert-particle**, **droplet-particle**, and/or **combusting-particle** will also appear.

Order Materials by

allows you to order the materials in the **Materials** list alphabetically by **Name** or alphabetically by **Chemical Formula**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Copy Materials from Case...
opens the Copy Case Material Dialog Box (p. 2315).

Delete
deletes the selected materials from the database.

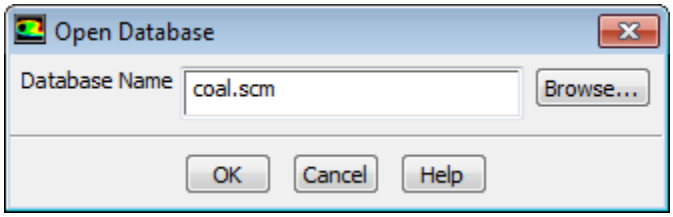
Properties
contains fields for the material properties that are defined for the selected material. These fields are for informational purposes only; they cannot be edited.

When you are viewing the database, not all properties displayed are relevant to your ANSYS Fluent solution. After you copy the material, only properties with relevance to the current physical models will be displayed.

Copy
copies the current material from the global database to the local materials list in the solver.

37.5.3. Open Database Dialog Box

The **Open Database** dialog box is opened by clicking the **User-Defined Database** button in the Create/Edit Materials Dialog Box (p. 2302).



Controls

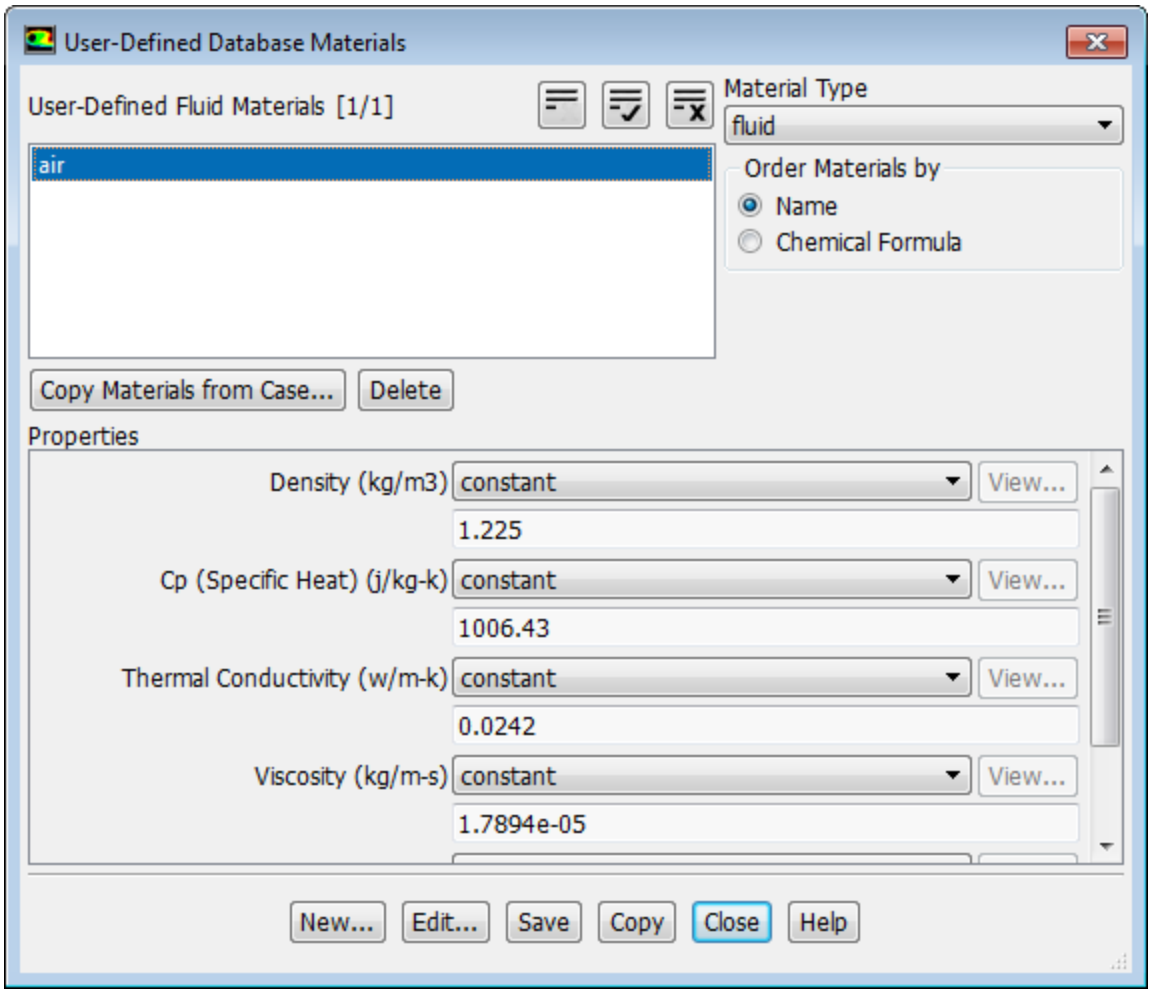
Browse...
opens The Select File Dialog Box (p. 19) where you can select the user-defined database to be used in the current solver session.

Database Name
allows you to enter the path and name of a new database. If you select an existing database, this field displays the path and name of the selected database.

37.5.4. User-Defined Database Materials Dialog Box

The **User-Defined Database Materials** dialog box is opened by clicking **OK** in the Open Database Dialog Box (p. 2313). In this dialog box you can view the user-defined material properties database and copy materials list in the solver. See Viewing Materials in a User-Defined Database (p. 468) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

User-Defined Materials
contains a list of all materials of the selected **Material Type** that are defined in the database. The name of this list will change depending on the selected material type (for example, **User-Defined Fluid Materials**, **User-Defined Solid Materials**, and so on). You can select one or more of these materials to copy to your local list or edit their properties.

Material Type
is a drop-down list containing all of the available material types.

Order Materials By
allows you to order the materials in the **User-Defined Materials** list alphabetically by **Name** or alphabetically by **Chemical Formula**.

Copy Materials from Case...
opens the Copy Case Material Dialog Box (p. 2315).

Delete
deletes the selected materials from the database.

Properties
lists the properties and values of the selected material.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

New...
opens a blank Material Properties Dialog Box (p. 2315) where you can define a new material.

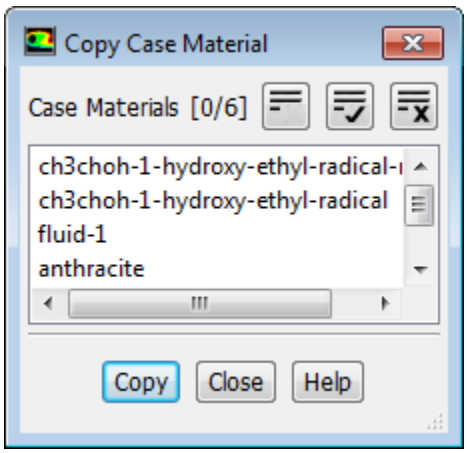
Edit...
opens the Material Properties Dialog Box (p. 2315) displaying the properties of the selected material.

Save
saves the information to the selected database.

Copy
copies the selected material to your local material list. If the material already exists the New Material Name Dialog Box (p. 2317) opens

37.5.5. Copy Case Material Dialog Box

This dialog box is opened by clicking the **Copy Materials from Case...** button in the User-Defined Database Materials Dialog Box (p. 2313).



Controls

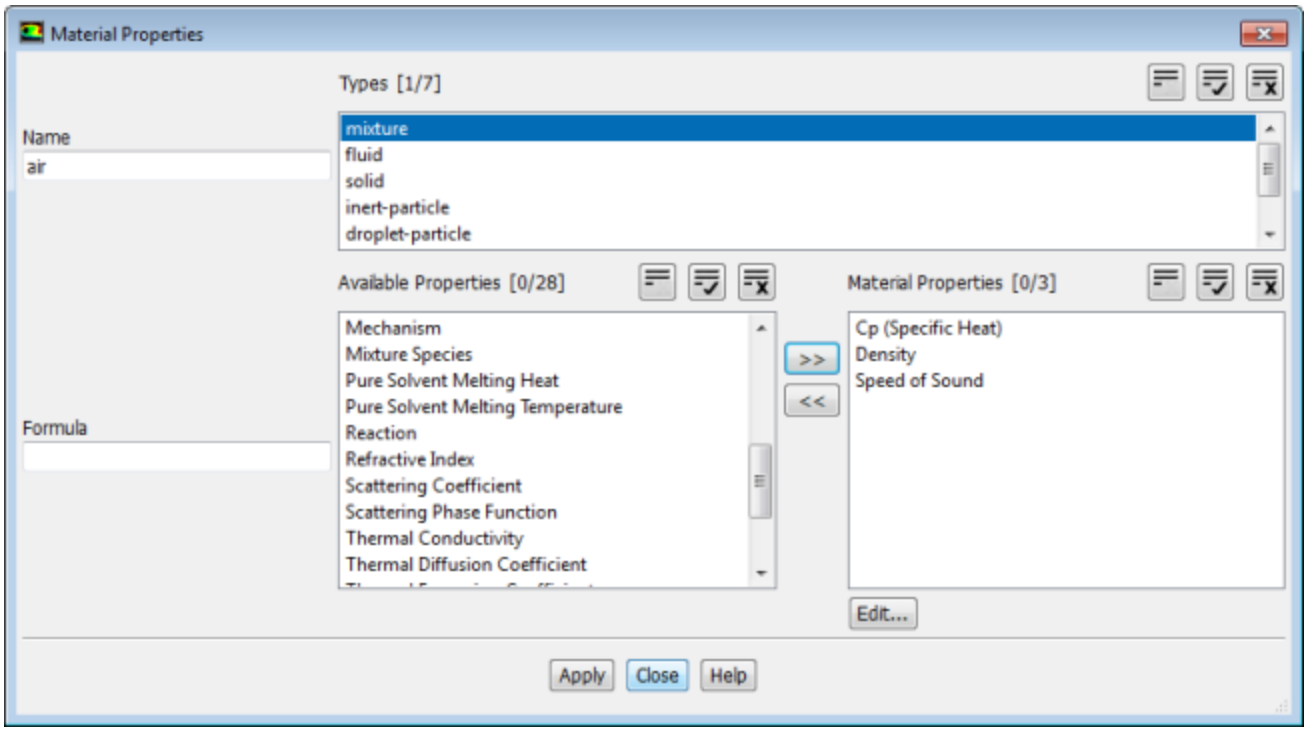
Case Materials
lists all the materials present in your local materials list.

Copy
copies the selected materials to the user-defined database.

37.5.6. Material Properties Dialog Box

This dialog box is opened by clicking **New...** button in the User-Defined Database Materials Dialog Box (p. 2313). See Creating a New Materials Database and Materials (p. 472) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
specifies the name of the material that you are creating.

Formula
(optional) specifies the chemical formula of the material that you are creating.

Types
allows you to select material type from fluid, solid, inter-particle, droplet-particle, combusting-particle, and mixture materials.

Available Properties
lists properties applicable to the selected material type.

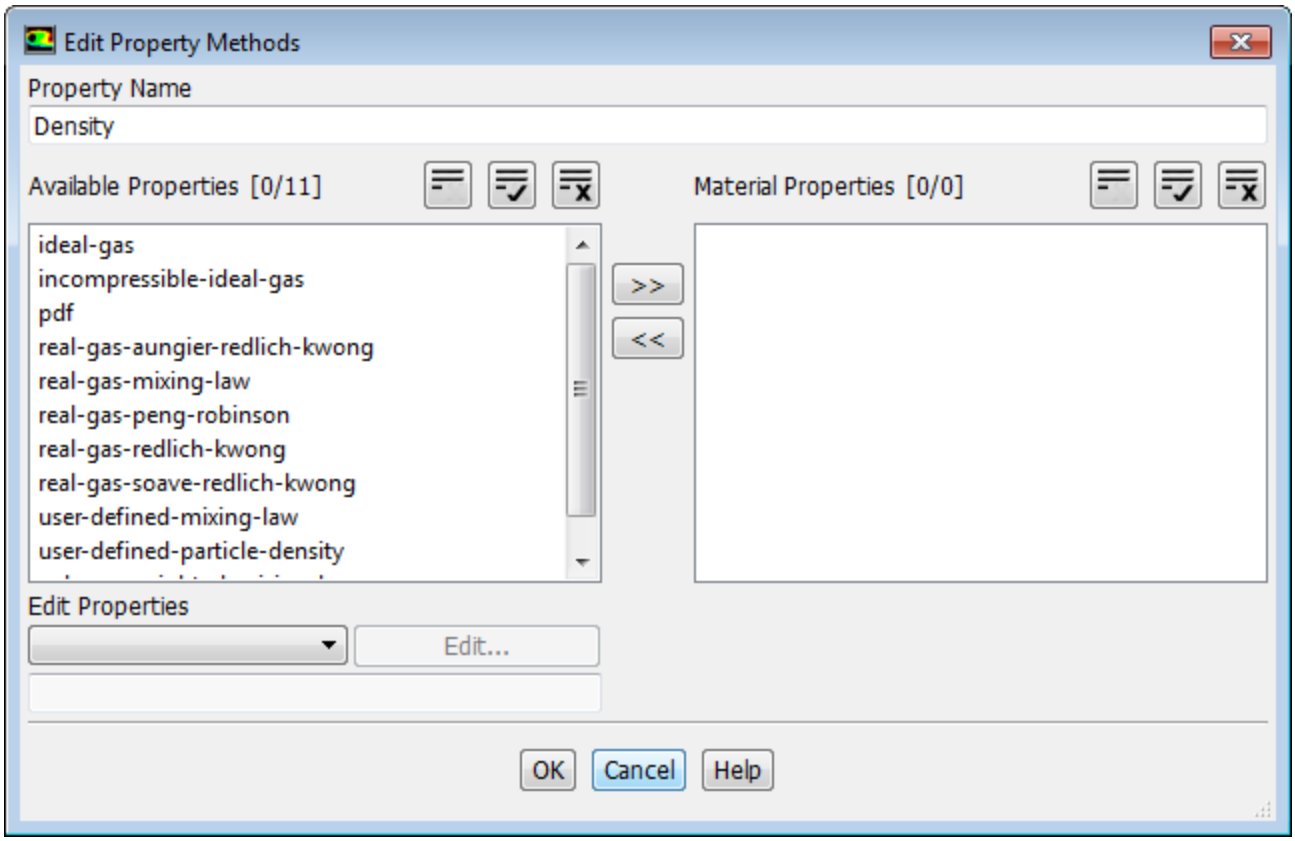
Material Properties
lists properties that you have selected from **Available Properties** list.

Edit...
opens Edit Property Methods Dialog Box (p. 2316) where you can edit the parameters that define a property.

37.5.7. Edit Property Methods Dialog Box

This dialog box is opened by clicking **Edit...** button in the Material Properties Dialog Box (p. 2315). See Creating a New Materials Database and Materials (p. 472) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Property Name
specifies the name of the property that you want to edit.

Available Properties
specifies the methods that can be used to define the selected property.

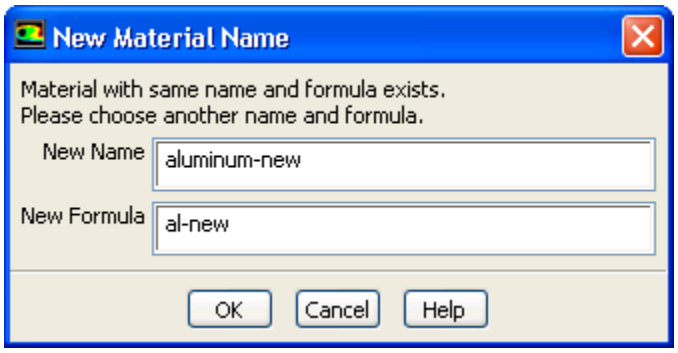
Material Properties
lists properties that you have selected from **Available Properties** list.

Edit Properties
allows you to select the property that you want to edit.

37.5.8. New Material Name Dialog Box

This dialog box is opened by clicking the **Copy** button in the User-Defined Database Materials Dialog Box (p. 2313) when a material is already defined with the same name in the Create/Edit Materials Dialog Box (p. 2302).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



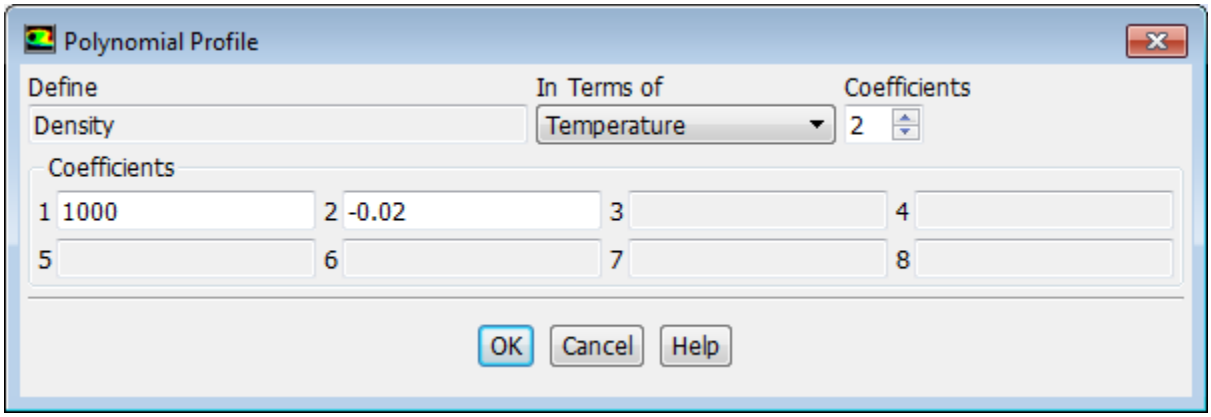
Controls

New Name
allows you to enter the new name for the material you need to copy.

New Formula
allows you to enter the new formula for the material you need to copy.

37.5.9. Polynomial Profile Dialog Box

The **Polynomial Profile** dialog box allows you to define a physical property as a polynomial function of temperature. This dialog box will open when you select **polynomial** in the drop-down list next to a physical property in the Create/Edit Materials Dialog Box (p. 2302). See Inputs for Polynomial Functions (p. 475) for details about the items below.



Controls

Define
shows the property that is being defined as a function of temperature.

In Terms of
shows the independent variable (**Temperature**). The property shown in **Define** will be defined as a polynomial function of temperature.

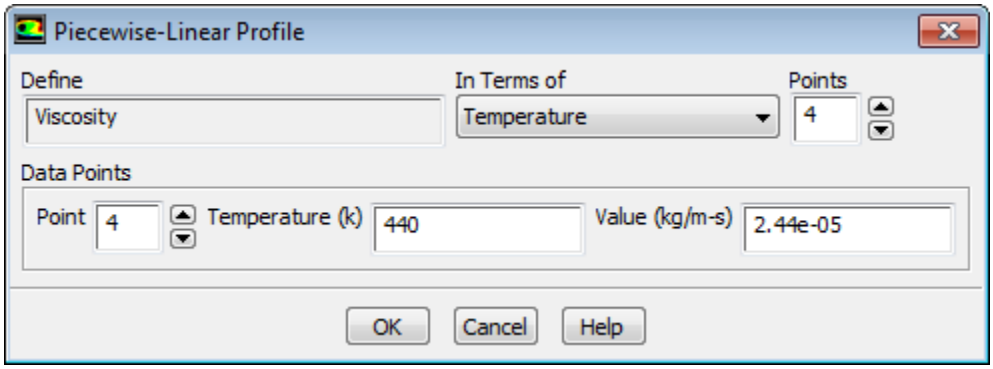
Coefficients
is an integer number entry that indicates the number of coefficients to be defined. You can define up to 8 coefficients.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Coefficients
contains real number entries for the number of coefficients set in the **Coefficients** integer number entry above. The number of entries that are editable will be the same as the number of coefficients you requested.

37.5.10. Piecewise-Linear Profile Dialog Box

The **Piecewise-Linear Profile** dialog box allows you to define a physical property as a piecewise-linear function of temperature. This dialog box will open when you select **piecewise-linear** in the drop-down list next to a physical property in the Create/Edit Materials Dialog Box (p. 2302). See Inputs for Piecewise-Linear Functions (p. 476) for details about the items below.



Controls

Define
shows the property that is being defined as a function of temperature.

In Terms of
shows the independent variable (**Temperature**). The property shown in **Define** will be defined as a piecewise-linear function of temperature.

Points
indicates the number of data pairs that will define the piecewise distribution. You can define up to 50 pairs.

Data Points
contains entries for defining the data pairs.

Point
indicates the point for which the data pair (**Temperature**, **Value**) is being defined.

Temperature
is the independent variable.

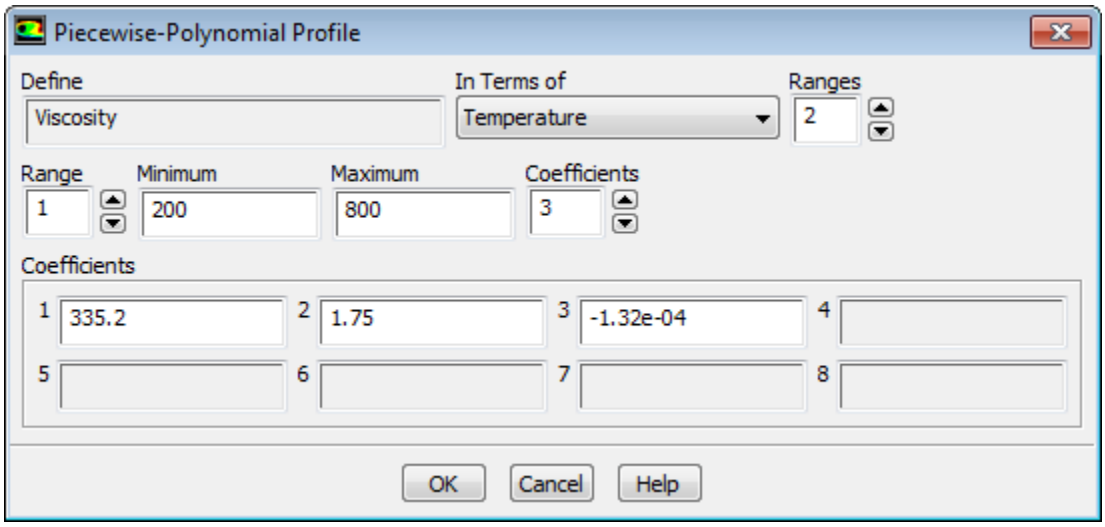
Value
is the dependent variable (the property). In the example dialog box above, **Viscosity** is the variable being defined, as shown in the **Define** field.

37.5.11. Piecewise-Polynomial Profile Dialog Box

The **Piecewise-Polynomial Profile** dialog box allows you to define a physical property as a piecewise-polynomial function of temperature. This dialog box will open when you select **piecewise-polynomial**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in the drop-down list next to a physical property in the Create/Edit Materials Dialog Box (p. 2302). See Inputs for Piecewise-Polynomial Functions (p. 478) for details about the items below.



Controls

Define
shows the property that is being defined as a function of temperature.

In Terms of
shows the independent variable (**Temperature**). The property shown in **Define** will be defined as a polynomial function of temperature.

Ranges
sets the number of temperature ranges for which you will define polynomial functions. You can define up to 3 ranges.

Range
indicates the temperature range for which you are defining the polynomial function.

Minimum, Maximum
set the minimum and maximum temperatures for the specified **Range**.

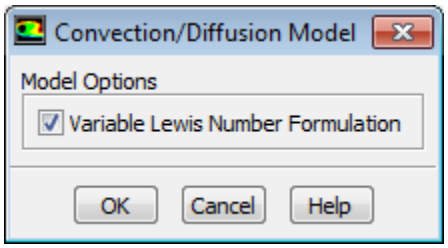
Coefficients
is an integer number entry that indicates the number of coefficients to be defined for the specified **Range**. You can define up to 8 coefficients.

Coefficients
contains real number entries for the number of coefficients set in the **Coefficients** integer number entry above. The number of entries that are editable will be the same as the number of coefficients you requested for the specified **Range**.

37.5.12. Convection/Diffusion Model Dialog Box

The **Convection/Diffusion Model** dialog box allows you to enable the calculation of the Spalding heat number when the **convection/diffusion-controlled** option is selected for **Vaporization Model** in the Create/Edit Materials Dialog Box (p. 2302). This dialog box opens when you click **Edit...** next to **Vaporization Model**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

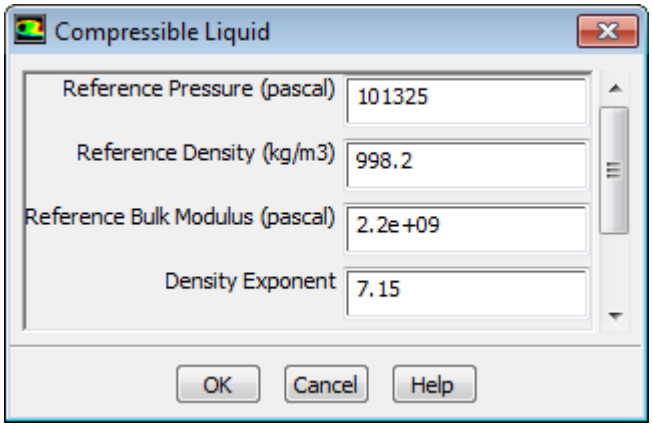


Model Options

allows you to enable **Variable Lewis Number Formulation** if you want to compute the Spalding heat number from Equation 16.115 in the *Fluent Theory Guide*.

37.5.13. Compressible Liquid Dialog Box

The **Compressible Liquid** dialog box allows you to model liquid compressibility for high pressure applications using the Tait equation of state. This dialog box will open when you select **compressible-liquid** in the drop-down list next to one of the **Properties** in the Create/Edit Materials Dialog Box (p. 2302). See Compressible Liquid Density Method (p. 480) for details about using the items below.



Controls

Reference Pressure

sets the reference pressure.

Reference Density

sets the reference density.

Reference Bulk Modulus

sets the reference bulk modulus.

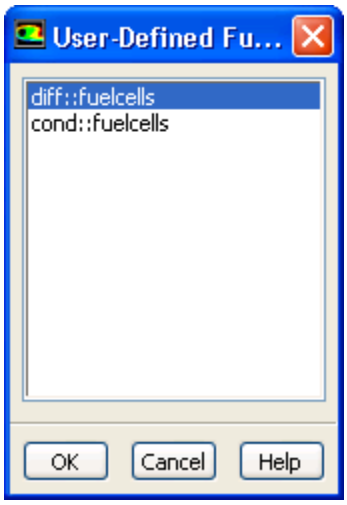
Density Exponent

sets the density exponent.

37.5.14. User-Defined Functions Dialog Box

The **User-Defined Functions** dialog box allows you to choose which user-defined function is to be used to define a material property. This dialog box will open when you select **user-defined** in the drop-down list next to one of the **Properties** in the Create/Edit Materials Dialog Box (p. 2302). See the separate Fluent Customization Manual for details about user-defined functions.

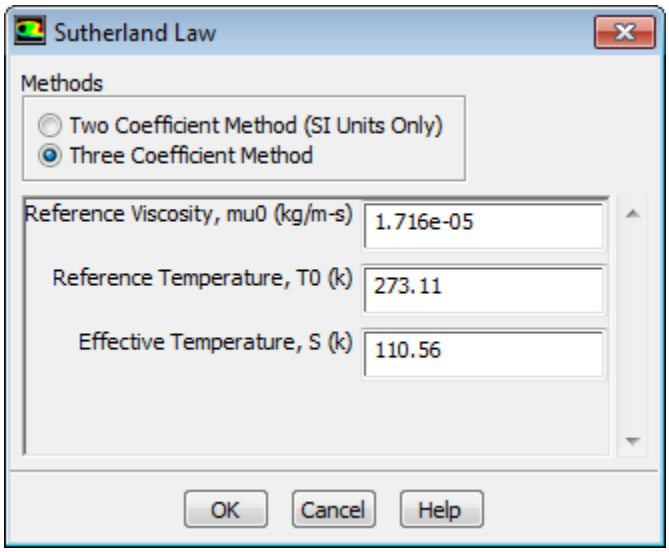
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The list will contain all available user-defined functions.

37.5.15. Sutherland Law Dialog Box

The **Sutherland Law** dialog box allows you to set the coefficients for Sutherland's law for viscosity. This dialog box will open when you select **sutherland** in the drop-down list next to **Viscosity** in the Create/Edit Materials Dialog Box (p. 2302). See Sutherland Viscosity Law (p. 489) for details about the items below.



Controls

Methods
contains options for selecting the **Two Coefficient Method** or the **Three Coefficient Method**.

C1, C2
set the coefficients C_1 and C_2 in Equation 7.23 (p. 489) in SI units. These inputs will appear if you select the **Two Coefficient Method**.

Reference Viscosity
sets the reference viscosity μ_0 in Equation 7.24 (p. 489). This input will appear if you select the **Three Coefficient Method**.

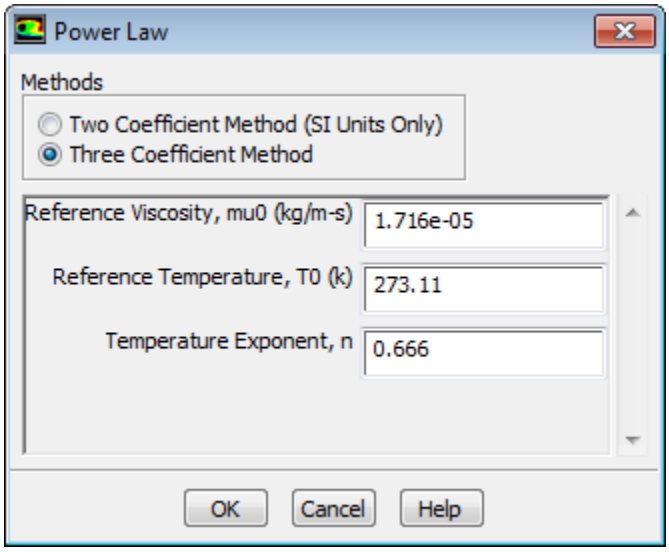
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reference Temperature
sets the reference temperature T_0 in Equation 7.24 (p. 489). This input will appear if you select the **Three Coefficient Method**.

Effective Temperature
sets the effective temperature S in Equation 7.24 (p. 489). This input will appear if you select the **Three Coefficient Method**.

37.5.16. Power Law Dialog Box

The **Power Law** dialog box allows you to set the coefficients for the power law for viscosity. This dialog box will open when you select **power-law** in the drop-down list next to **Viscosity** in the Create/Edit Materials Dialog Box (p. 2302). See Power-Law Viscosity Law (p. 489) for details about the items below.



Controls

Methods
contains options for selecting the **Two Coefficient Method** or the **Three Coefficient Method**.

B
sets the coefficient B in Equation 7.25 (p. 490) in SI units. This input will appear if you select the **Two Coefficient Method**.

Reference Viscosity
sets the reference viscosity μ_0 in Equation 7.26 (p. 490). This input will appear if you select the **Three Coefficient Method**.

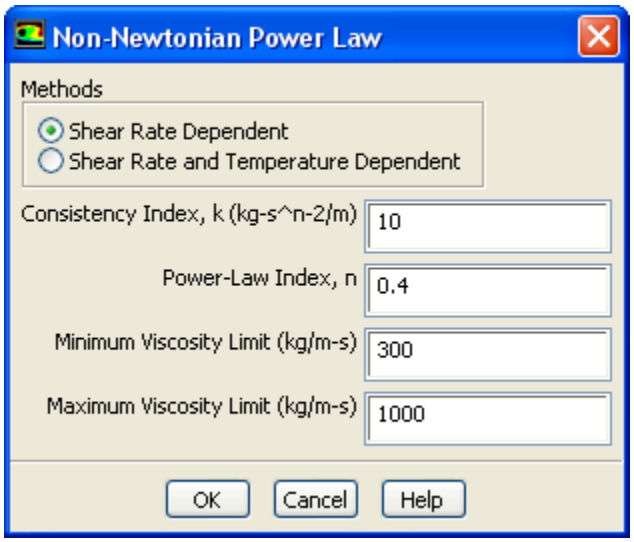
Reference Temperature
sets the reference temperature T_0 in Equation 7.26 (p. 490). This input will appear if you select the **Three Coefficient Method**.

Temperature Exponent
sets the temperature exponent n in Equation 7.25 (p. 490) or Equation 7.26 (p. 490), depending on your **Method** selection. If you are using the **Two Coefficient Method**, this input must be in SI units.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.17. Non-Newtonian Power Law Dialog Box

The **Non-Newtonian Power Law** dialog box allows you to set the parameters for the non-Newtonian power law for viscosity. This dialog box will open when you select **non-newtonian-power-law** in the drop-down list next to **Viscosity** in the Create/Edit Materials Dialog Box (p. 2302). See Power Law for Non-Newtonian Viscosity (p. 493) for details about the items below.



Controls

Methods
allows you to select the type of dependency on the viscosity.

Shear Rate Dependent
is where the viscosity is dependent on the shear rate.

Shear Rate and Temperature Dependent
is where the viscosity is dependent on the shear rate and the temperature.

Consistency Index
sets the consistency index k in Equation 7.38 (p. 493).

Power-Law Index
sets the power-law index n in Equation 7.38 (p. 493).

Minimum Viscosity Limit, Maximum Viscosity Limit
set the minimum and maximum viscosity limits.

Reference Temperature
sets the reference temperature.

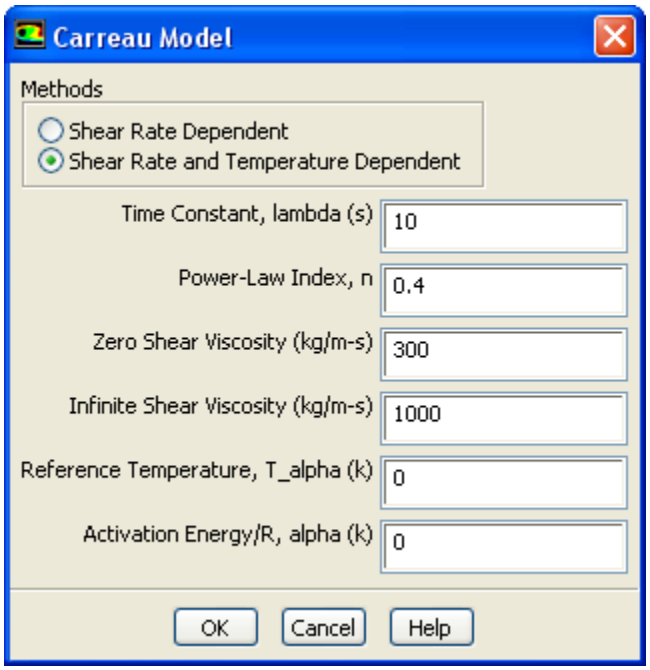
Activation Energy/R, alpha
is the ratio of the activation energy to the thermodynamic constant α in Equation 7.37 (p. 493).

37.5.18. Carreau Model Dialog Box

The **Carreau Model** dialog box allows you to set the parameters for the non-Newtonian Carreau model for viscosity. This dialog box will open when you select **carreau** in the drop-down list next to **Viscosity**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in the Create/Edit Materials Dialog Box (p. 2302). See The Carreau Model for Pseudo-Plastics (p. 494) for details about the items below.



Controls

Methods
allows you to select the type of dependency on the viscosity.

Shear Rate Dependent
is where the viscosity is dependent on the shear rate.

Shear Rate and Temperature Dependent
is where the viscosity is dependent on the shear rate and the temperature.

Time Constant, lambda
sets the time constant λ in Equation 7.39 (p. 494).

Power-Law Index
sets the power-law index n in Equation 7.39 (p. 494).

Zero Shear Viscosity, Infinite Shear Viscosity
set the zero and infinite shear viscosity limits η_0 and η_∞ in Equation 7.39 (p. 494).

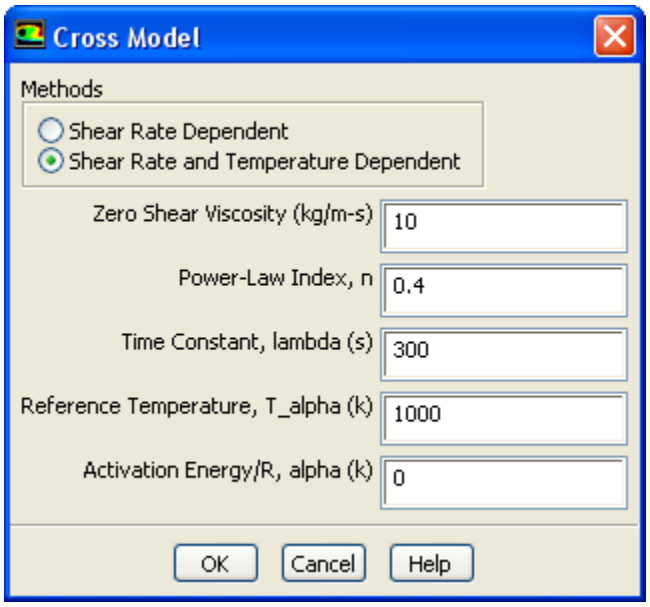
Reference Temperature, T_alpha
sets the reference temperature T_0 in Equation 7.39 (p. 494).

Activation Energy/R, alpha
is the ratio of the activation energy to the thermodynamic constant α in Equation 7.37 (p. 493).

37.5.19. Cross Model Dialog Box

The **Cross Model** dialog box allows you to set the parameters for the non-Newtonian Cross model for viscosity. This dialog box will open when you select **cross** in the drop-down list next to **Viscosity** in the Create/Edit Materials Dialog Box (p. 2302). See Cross Model (p. 495) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Methods
allows you to select the type of dependency on the viscosity.

Shear Rate Dependent
is where the viscosity is dependent on the shear rate.

Shear Rate and Temperature Dependent
is where the viscosity is dependent on the shear rate and the temperature.

Zero Shear Viscosity
sets the zero shear viscosity limit η_0 in Equation 7.40 (p. 495).

Power-Law Index
sets the power-law index n in Equation 7.40 (p. 495).

Time Constant
sets the time constant λ in Equation 7.40 (p. 495).

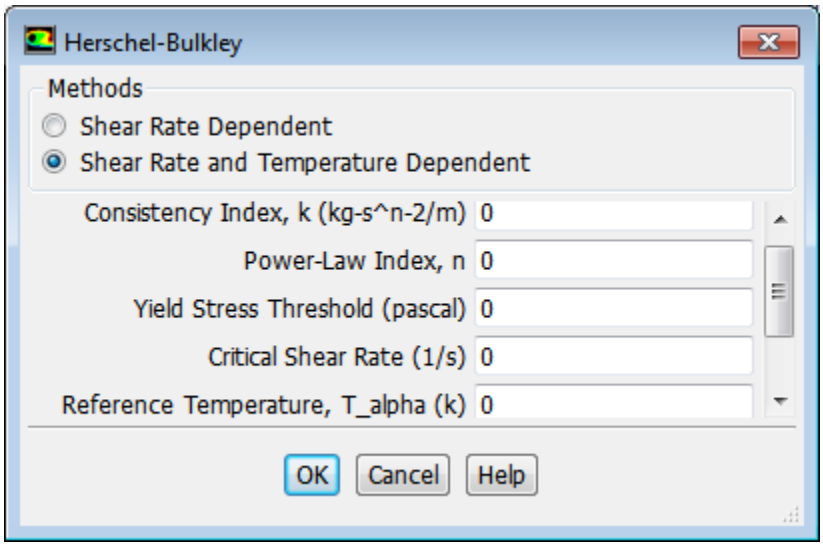
Reference Temperature, T_alpha
sets the reference temperature T_0 in Equation 7.39 (p. 494).

Activation Energy/R, alpha
is the ratio of the activation energy to the thermodynamic constant α in Equation 7.37 (p. 493).

37.5.20. Herschel-Bulkley Dialog Box

The **Herschel-Bulkley** dialog box allows you to set the parameters for the non-Newtonian Herschel-Bulkley model for viscosity. This dialog box will open when you select **herschel-bulkley** in the drop-down list next to **Viscosity** in the Create/Edit Materials Dialog Box (p. 2302). See Herschel-Bulkley Model for Bingham Plastics (p. 495) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Methods
allows you to select the type of dependency on the viscosity.

Shear Rate Dependent
is where the viscosity is dependent on the shear rate.

Shear Rate and Temperature Dependent
is where the viscosity is dependent on the shear rate and the temperature.

Consistency Index
sets the consistency index k in Equation 7.42 (p. 496).

Power-Law Index
sets the power-law index n in Equation 7.42 (p. 496).

Yield Stress Threshold
sets the yield stress threshold τ_0 in Equation 7.42 (p. 496).

Critical Shear Rate
set the critical shear rate $\dot{\gamma}_c$ in Equation 7.42 (p. 496).

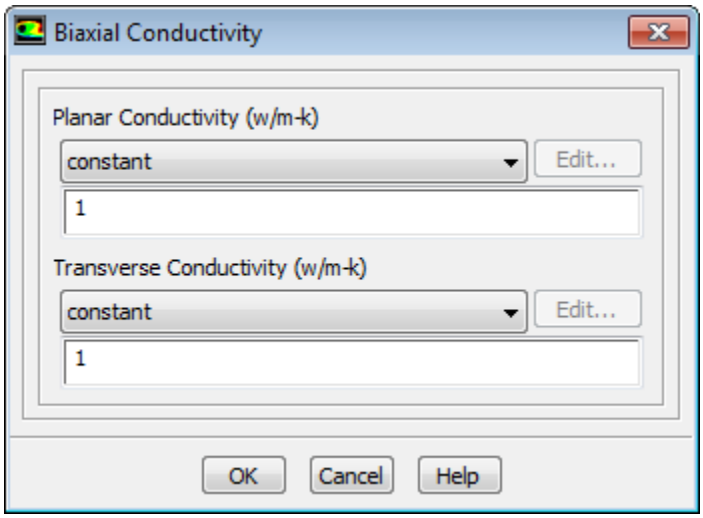
Reference Temperature, T_alpha
sets the reference temperature T_α in Equation 7.37 (p. 493).

Activation Energy/R, alpha
is the ratio of the activation energy to the thermodynamic constant α in Equation 7.37 (p. 493).

37.5.21. Biaxial Conductivity Dialog Box

The **Biaxial Conductivity** dialog box allows you to define a biaxial orthotropic thermal conductivity, which is applicable to solid materials used for the wall shell conduction model. This dialog box will open when you select **biaxial** in the drop-down list next to **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2302). See Biaxial Thermal Conductivity (p. 502) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

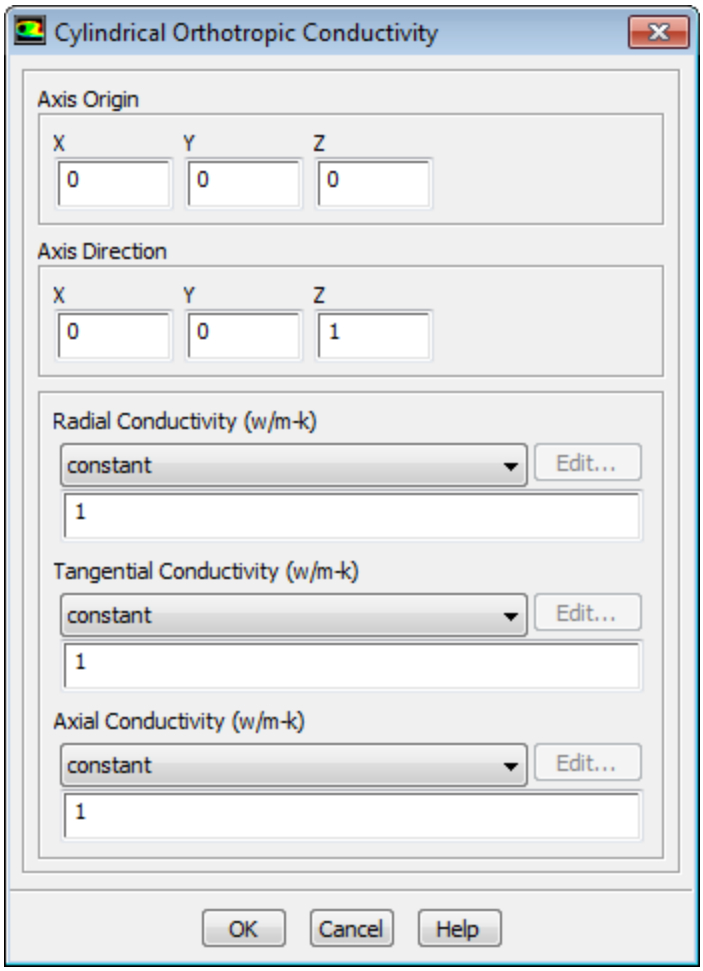
Planar Conductivity
specifies the conductivity within the shell (or solid) region.

Transverse Conductivity
specifies the conductivity normal to the surface of the solid region.

37.5.22. Cylindrical Orthotropic Conductivity Dialog Box

The **Cylindrical Orthotropic Conductivity** dialog box allows you to define an orthotropic thermal conductivity in cylindrical coordinates. This dialog box will open when you select **cyl-orthotropic** in the drop-down list next to **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2302). See Cylindrical Orthotropic Thermal Conductivity (p. 504) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Axis Origin

allows you to specify the origin of the cylindrical coordinate system.

X, Y, Z

specify the X, Y, and (for 3D cases) Z coordinates.

Axis Direction

(3D only) allows you to specify the direction of the axis.

X, Y, Z

specify 1 against the direction of the axis.

Radial Conductivity

specifies the conductivity in the radial direction.

Tangential Conductivity

specifies the conductivity in the tangential direction.

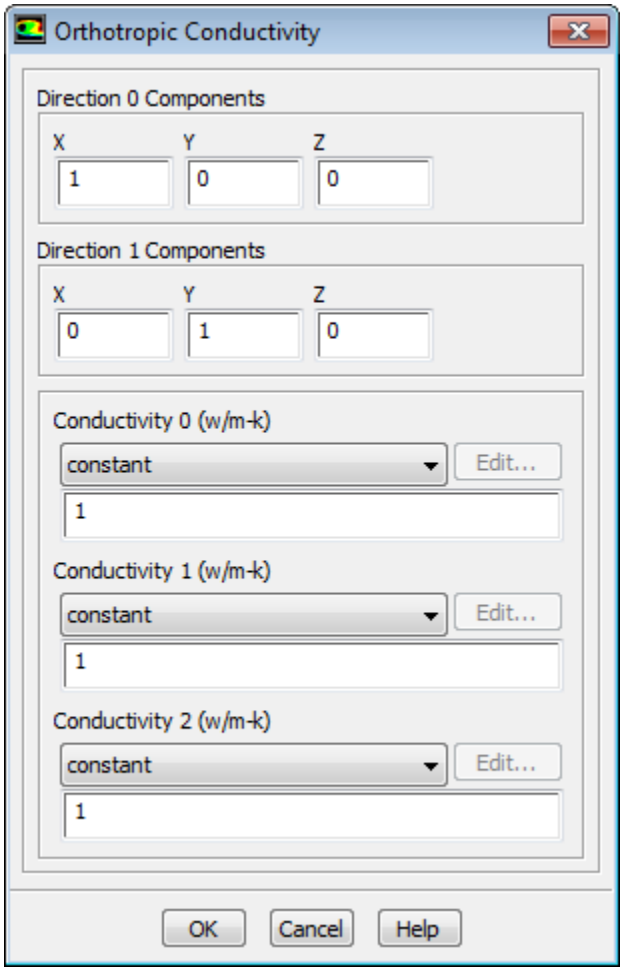
Axial Conductivity

(3D only) specifies the conductivity in the axial direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.23. Orthotropic Conductivity Dialog Box

The **Orthotropic Conductivity** dialog box allows you to define an orthotropic thermal conductivity for a solid material, using principal directions that do not have to aligned with the global coordinate system of the simulation. This dialog box will open when you select **orthotropic** in the drop-down list next to **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2302). See Orthotropic Thermal Conductivity (p. 503) for details about the items below.



Controls

Direction 0 Components, Direction 1 Components

specify the directions $\hat{e}_\xi$ and $\hat{e}_\eta$ in Equation 7.53 (p. 503) as **X,Y,Z** vectors. For 2D cases, only **Direction 0 Components** will appear.

Conductivity 0, Conductivity 1, Conductivity 2

specify $\left(k_\xi\right)$, $\left(k_\eta\right)$, and $\left(k_\zeta\right)$ in Equation 7.53 (p. 503) as **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** functions of temperature. For 2D cases, only **Conductivity 0** and **Conductivity 1** will appear.

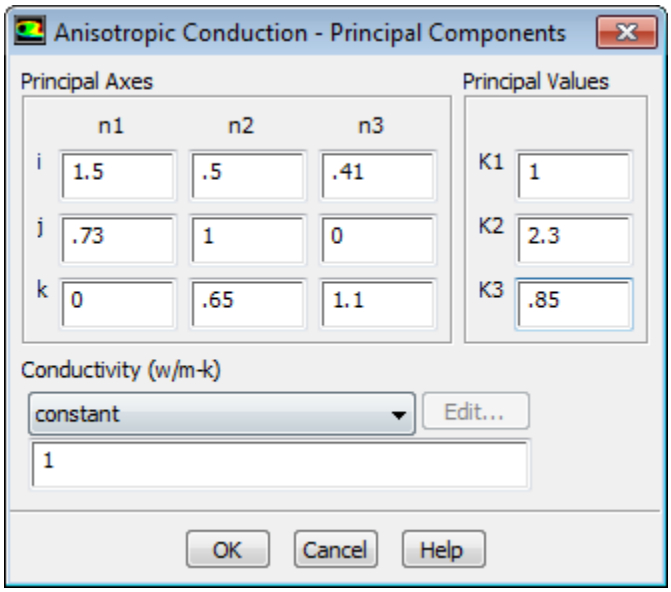
Edit...

opens the appropriate dialog box so you can enter a temperature-dependent conductivity. (This button will be unavailable if you specify a **constant** conductivity.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.24. Anisotropic Conductivity - Principal Components Dialog Box

The **Anisotropic Conductivity - Principal Components** dialog box allows you to define an anisotropic thermal conductivity using the components of the principal axes (which do not have to be orthogonal and/or aligned with the global coordinate system) and the associated principal values. This dialog box will open when you select **principal-axes-values** in the drop-down list next to **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2302). See Principal Axes and Principal Values (p. 506) for details about the items that follow.



Controls

Principal Axes

specifies the $\hat{i}$, $\hat{j}$, and $\hat{k}$ components of the $\vec{n}^1$, $\vec{n}^2$, and $\vec{n}^3$ vectors (in Equation 7.54 (p. 506)) that define the principal axes of the anisotropic material. Note that these vectors must be linearly independent.

Principal Values

specifies the principal values (K_1, K_2, and K_3 in Equation 7.57 (p. 506)) associated with the principal axes.

Conductivity

specifies the value of k (in Equation 7.57 (p. 506)) as a **constant**, function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined** function.

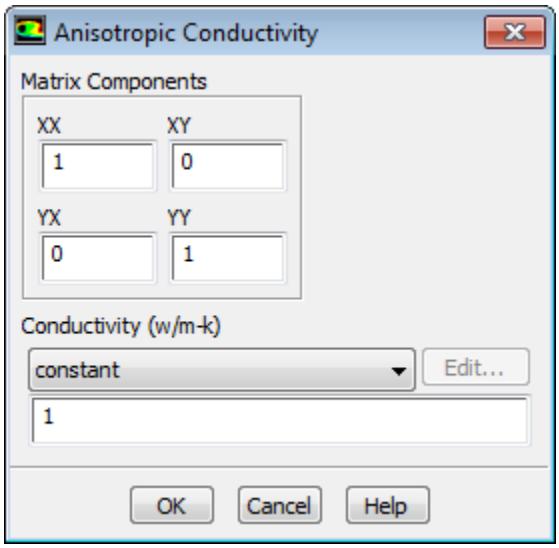
Edit...

opens the appropriate dialog box for the definition of a temperature-dependent or user-defined conductivity. (This button will be unavailable if you specify a **constant** conductivity.)

37.5.25. Anisotropic Conductivity Dialog Box

The **Anisotropic Conductivity** dialog box allows you to define a general anisotropic thermal conductivity. This dialog box will open when you select **anisotropic** in the drop-down list next to **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2302). See Anisotropic Thermal Conductivity (p. 501) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Matrix Components
specify the components of the matrix $\hat{e}_{ij}$ in Equation 7.52 (p. 501).

Conductivity
specifies the value of k in Equation 7.52 (p. 501) as a **constant**, function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined** function.

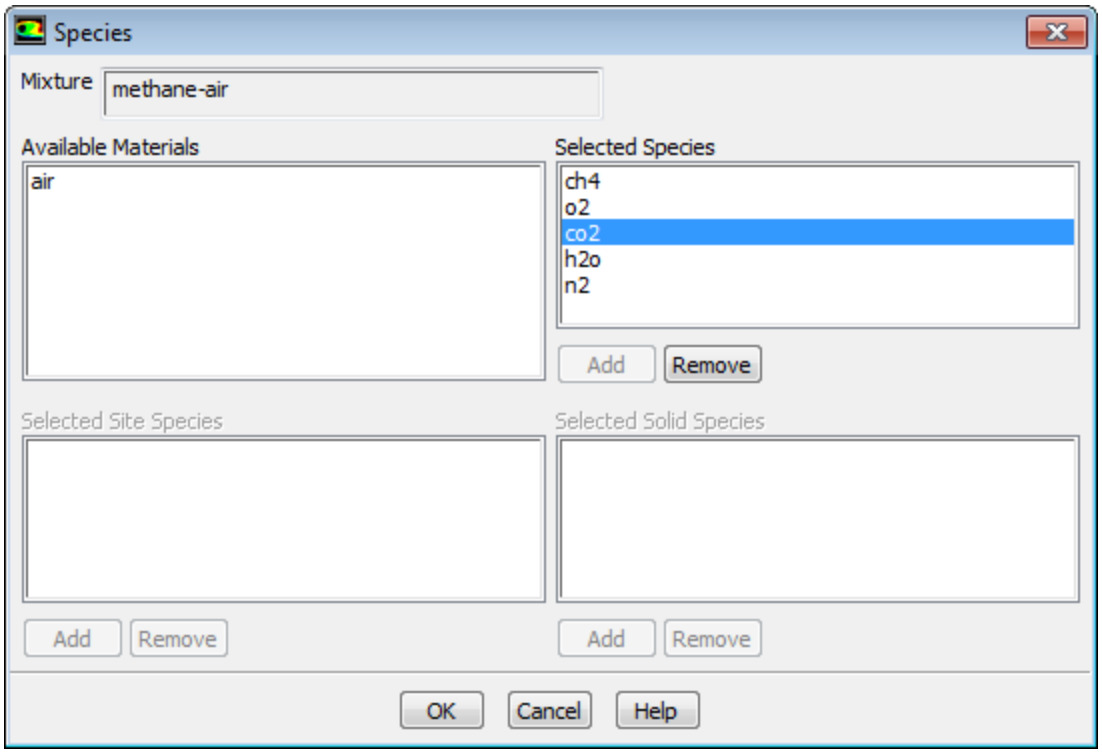
Edit...
opens the appropriate dialog box so you can enter a temperature-dependent or user-defined conductivity. (This button will be unavailable if you specify a **constant** conductivity.)

37.5.26. Species Dialog Box

The **Species** dialog box (opened by clicking the **Edit...** button next to **Mixture Species** in the Create/Edit Materials Dialog Box (p. 2302))) allows you to define the species that comprise a mixture material. See Defining the Species in the Mixture (p. 973) for details about the items below.

(Note that the **Species** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Mixture

shows the name of the mixture material for which you are defining the species. This field is not editable.

Available Materials

is a list of all of the materials to be a component in the mixture material by selecting it and clicking the **Add** button below the **Selected Species** or **Selected Surface Species** list. To add a material to the **Available Materials** list, use the Fluent Database Materials Dialog Box (p. 2312) to copy the fluid material to local storage.

Selected Species

is a list of all the fluid-phase species in the mixture. To add a material to the list, select it in the **Available Materials** list and click the **Add** button below the **Selected Species** list. To remove a material, select it in the **Selected Species** list and click **Remove**. See Overview of the Species Dialog Box (p. 974) for more information.

Selected Solid Species

is a list of all the solid species in the mixture. To add a material to the list, select it in the **Available Materials** list and click the **Add** button below the **Selected Solid Species** list. To remove a material, select it in the **Selected Solid Species** list and click **Remove**. See Overview of the Species Dialog Box (p. 974) for more information.

Selected Site Species

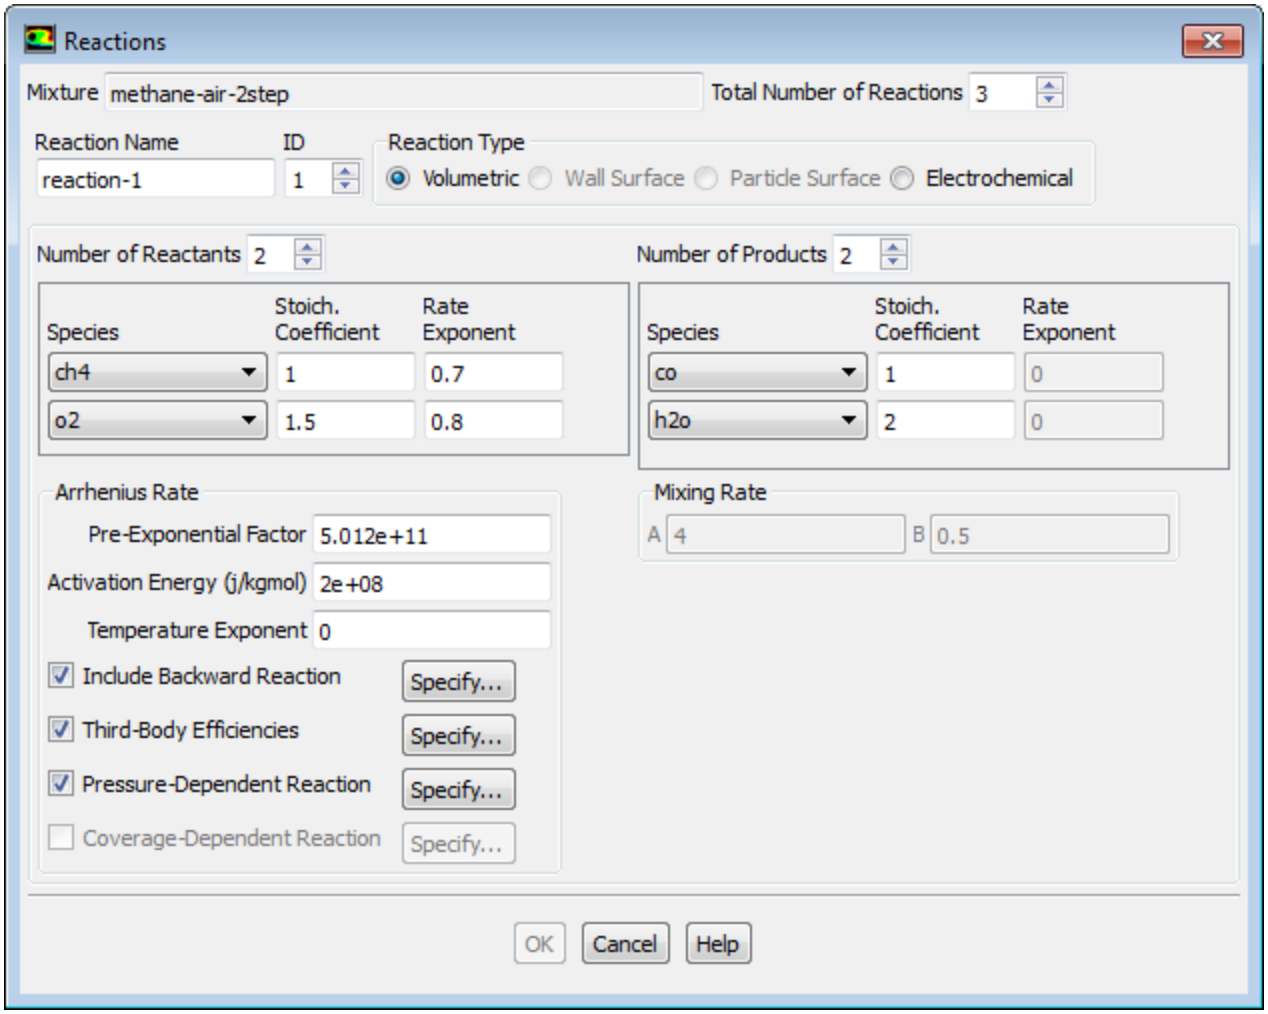
is a list of all the site species in the mixture. To add a material to the list, select it in the **Available Materials** list and click the **Add** button below the **Selected Site Species** list. To remove a material, select it in the **Selected Site Species** list and click **Remove**. See Overview of the Species Dialog Box (p. 974) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.27. Reactions Dialog Box

The **Reactions** dialog box (opened by clicking the **Edit...** button next to **Reaction** in the Create/Edit Materials Dialog Box (p. 2302)) allows you to define the reactions that comprise a mixture material. See Defining Reactions (p. 977) for details about using this dialog box.

(Note that the **Reactions** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)



Controls

Mixture

shows the name of the mixture material for which you are defining the species. This field is not editable.

Total Number of Reactions

sets the total number of reactions (fluid-phase reactions and surface reactions occurring at wall boundaries). Use the arrows to change the value, or type in the value and press RETURN.

Reaction Name

contains the name of the reaction.

ID

sets the number of the reaction you want to define. (Again, if you type in the value be sure to press RETURN.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reaction Type
contains options that allow you to specify the type of reaction.

Volumetric
specifies, if enabled, that the current reaction is a volumetric reaction.

Wall Surface
specifies, if enabled, that the current reaction is a wall surface reaction.

Particle Surface
specifies, if enabled, that the current reaction is a particle surface reaction.

Number of Reactants
indicates the number of reactants in the specified reaction.

Species
contains drop-down lists of all species in the mixture. (The number of lists will be equal to the **Number of Reactants**.) Select each reactant in one of these lists.

Stoich. Coefficient
specifies the stoichiometric coefficient of the reactant species in the reaction.

Rate Exponent
specifies the rate constant for the reactant species in the reaction.

Number of Products
indicates the number of products in the specified reaction.

Species
contains drop-down lists of all species in the mixture. (The number of lists will be equal to the **Number of Products**.) Select each product in one of these lists.

Stoich. Coefficient
specifies the stoichiometric coefficient of the product species in the reaction.

Rate Exponent
specifies the rate constant for the product species in the reaction.

Arrhenius Rate
contains inputs related to the Arrhenius rate. (If you have chosen **Eddy-Dissipation** for the **Turbulence-Chemistry Interaction** in the Species Model Dialog Box (p. 2216), these inputs are not required.)

Pre-exponential Factor
is the constant A_r in Equation 7.9 in the Theory Guide. The units of A_r depend on the other rate constant inputs, but must be defined such that the units of the reaction rate $R_{i,r}$ (Equation 7.5 in the Theory Guide) are in (kg/m^3-s) if you are using SI units.

Important

It is important to note that if you have selected the British units system, the Arrhenius factor should still be specified in SI units. This is because ANSYS Fluent applies no conversion factor to the value you enter for A_r (the conversion factor is 1.0) when

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you work in British units, as the correct conversion factor depends on your values for $\nu_{j,r}$, β_r, and so on.

Activation Energy
is the constant E_r in the forward rate constant expression, Equation 7.9 in the Theory Guide).

Temperature Exponent
is the value for the constant β_r in Equation 7.9 in the Theory Guide.

Include Backward Reaction
specifies that the reaction is reversible. By default, the backward reaction rate constant will be computed from Equation 7.9 in the *Fluent Theory Guide*. You can specify your own backward reaction rate parameters in the Backward Reaction Parameters Dialog Box (p. 2337). In this case, the backward reaction rate constant will be computed from Equation 7.14 in the *Fluent Theory Guide*.

Third-Body Efficiencies
allows you to specify and use third-body efficiencies ($\gamma_{j,r}$ in Equation 7.8 in the Theory Guide). These inputs are optional. (This item is available only if you have selected **Volumetric** for the **Reaction Type**.)

Pressure-Dependent Reaction
enables the modeling of a pressure fall-off reaction. See Inputs for Reaction Definition (p. 977) **Laminar Finite-Rate** or **Eddy-Dissipation Concept** for the **Turbulence-Chemistry Interaction** in the Species Model Dialog Box (p. 2216) and have selected **Volumetric** for the **Reaction Type**.)

Coverage-Dependent Reaction
is used when modeling **Wall Surface** reactions with site-balancing and reaction rates depend on site coverages.

Specify...
opens the Backward Reaction Parameters Dialog Box (p. 2337), Third-Body Efficiency Dialog Box (p. 2338), the Pressure-Dependent Reaction Dialog Box (p. 2339), or Coverage-Dependent Reaction Dialog Box (p. 2341) in which you can specify the backward rate parameters for the reversible reaction, third-body efficiencies, pressure-dependent reaction parameters, or coverage parameters.

Mixing Rate
contains inputs related to the mixing rate. (If you have chosen **Laminar Finite-Rate** or **Eddy-Dissipation Concept** for the **Turbulence-Chemistry Interaction** in the Species Model Dialog Box (p. 2216), these inputs are not required.)

A
is the constant A in the turbulent mixing rate (Equation 7.25 and Equation 7.26 in the Theory Guide) when it is applied to a species that appears as a reactant in this reaction. The default setting of 4.0 is based on the empirically derived values given by Magnussen and Hjertager [64] (p. 2890).

B
is the constant B in the turbulent mixing rate (Equation 7.26 in the Theory Guide) when it is applied to a species that appears as a product in this reaction. The default setting of 0.5 is based on the empirically derived values given by Magnussen and Hjertager [64] (p. 2890).

Particle Surface Reaction
contains inputs related to a particle surface reaction. See User Inputs for Particle Surface Reactions (p. 1001) for details. (This section will appear only if you have selected **Particle Surface** for the **Reaction Type**.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Diffusion Limited Species
is a drop-down list that allows you to select the species for which the concentration gradient between the bulk and the particle surface is the largest when there is more than one gaseous reactant taking part in the particle surface reaction. See User Inputs for Particle Surface Reactions (p. 1001) for details.

Diffusion Rate Constant
is the constant $C_{1,r}$ in Equation 7.71 in the Theory Guide.

Effectiveness Factor
is the constant η_r in Equation 7.69 in the Theory Guide.

Butler-Volmer/Tafel Parameters
contains inputs related to an electrochemical reaction. See User Inputs for Electrochemical Reactions (p. 1004) for details. (This group box appears only if **Electrochemical** is selected for **Reaction Type**.)

Tafel Parameters
indicates whether the Bulter-Volmer equation (Equation 7.80 in the *Fluent Theory Guide*) or the Tafel equation (Equation 7.81 in the *Fluent Theory Guide*) is used in the kinetics calculation.

Anodic Transfer Coefficient
is the value of α_a used in Equation 7.80 in the *Fluent Theory Guide*. This item appears if the **Tafel Parameters** check box is cleared.

Cathodic Transfer Coefficient
is the value of α_c used in Equation 7.80 in the *Fluent Theory Guide*. This item appears if the **Tafel Parameters** check box is cleared.

Anodic Tafel Slope
is the value of $\beta_{a,r}$ in Equation 7.81 in the *Fluent Theory Guide*. This item appears only if the **Tafel Parameters** check box is selected.

Cathodic Tafel Slope
is the value of $\beta_{c,r}$ in Equation 7.81 in the *Fluent Theory Guide*. This item appears only if the **Tafel Parameters** check box is selected.

Exchange Current Density
is the value of i_o used in Equation 7.80 in the *Fluent Theory Guide*

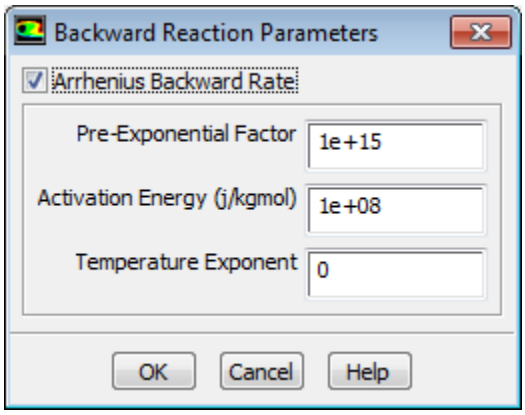
Equilibrium Potential
is the value of E_{eq} used in Equation 7.82 in the *Fluent Theory Guide*

Specify Reference Mass Fractions...
opens the Reference Mass Fractions Dialog Box (p. 2341).

37.5.28. Backward Reaction Parameters Dialog Box

The **Backward Reaction Parameters** dialog box (opened by clicking **Specify...** next to **Include Backward Reaction** in the Reactions Dialog Box (p. 2334)) allows you to specify your custom backward rate parameters for a reversible reaction. See Inputs for Reaction Definition (p. 977) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Arrhenius Backward Rate
allows you to specify backward rate parameters.

Pre-Exponential Factor
is the constant $A_{b,r}$ in Equation 7.14 in the *Fluent Theory Guide*.

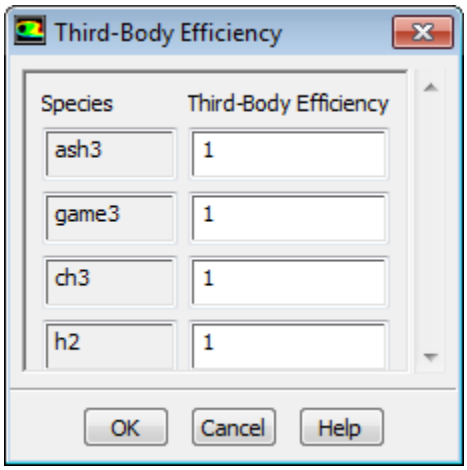
Activation Energy
is the constant $E_{b,r}$ in the backward rate constant expression in Equation 7.14 in the *Fluent Theory Guide*.

Temperature Exponent
is the constant $\beta_{b,r}$ in Equation 7.14 in the *Fluent Theory Guide*.

37.5.29. Third-Body Efficiency Dialog Box

The **Third-Body Efficiency** dialog box (opened by clicking **Specify...** next to the **Third-Body Efficiencies** button in the Reactions Dialog Box (p. 2334)) allows you to specify the third-body efficiencies for each species in the mixture, to be used in Equation 7.8 in the Theory Guide. See Defining Reactions (p. 977) for details.

(Note that the **Third-Body Efficiency** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)



Controls

Species
displays the name of each species in the mixture.

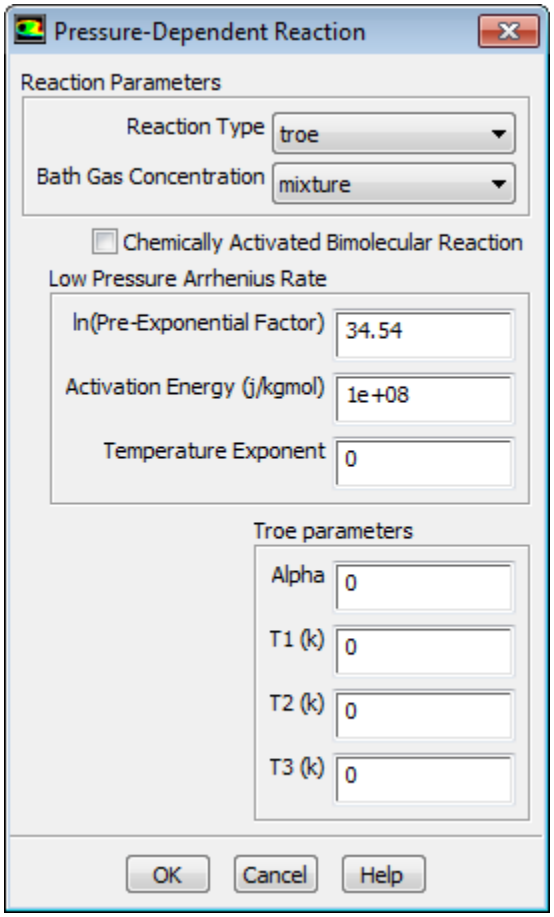
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Third-body Efficiency
specifies the third-body efficiency for each species.

37.5.30. Pressure-Dependent Reaction Dialog Box

The **Pressure-Dependent Reaction** dialog box (opened by clicking **Specify...** under **Pressure-Dependent Reaction** in the Reactions Dialog Box (p. 2334)) allows you to specify parameters for a pressure fall-off reaction. See Inputs for Reaction Definition (p. 977) for details.

(Note that the **Pressure-Dependent Reaction** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)



Controls

Reaction Parameters
contains inputs for specifying the type of pressure fall-off reaction and the reaction parameters. See Pressure-Dependent Reactions in the Theory Guide for details.

Reaction Type
contains a drop-down list of the available reaction types: **lindemann**, **troe**, and **sri**. See Pressure-Dependent Reactions in the Theory Guide for details.

Bath Gas Concentration
allows you to specify if the bath gas concentration ($[M]$ in Equation 7.18 in the Theory Guide) is to be defined as the concentration of the **mixture**, or as the concentration of one of the mixture's constituent species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chemically Activated Bimolecular Reaction
results in a net rate constant at any pressure being defined as Equation 7.24 in the Theory Guide.

Low Pressure Arrhenius Rate
contains inputs for specifying low-pressure Arrhenius parameters.

ln(Pre-exponential Factor)
is the natural logarithm of the constant A_{low} in Equation 7.16 in the Theory Guide. The pre-exponential factor A_{low} is often an extremely large number, so you will enter the natural logarithm of this term.

Activation Energy
is the constant E_{low} in Equation 7.16 in the Theory Guide.

Temperature Exponent
is the constant β_{low} in Equation 7.16 in the Theory Guide.

Troe parameters
contains inputs for specifying parameters for the Troe method. See Pressure-Dependent Reactions in the Theory Guide for details. (This section of the dialog box will appear only if you have selected **troe** as the **Reaction Type**.)

Alpha
is the constant α in Equation 7.21 in the Theory Guide.

T1
is the constant T_1 in Equation 7.21 in the Theory Guide.

T2
is the constant T_2 in Equation 7.21 in the Theory Guide.

T3
is the constant T_3 in Equation 7.21 in the Theory Guide.

SRI Parameters
contains inputs for specifying parameters for the SRI method. See Pressure-Dependent Reactions in the Theory Guide for details. (This section of the dialog box will appear only if you have selected **sri** as the **Reaction Type**.)

a
is the constant a in Equation 7.22 in the Theory Guide.

b
is the constant b in Equation 7.22 in the Theory Guide.

c
is the constant c in Equation 7.22 in the Theory Guide.

d
is the constant d in Equation 7.22 in the Theory Guide.

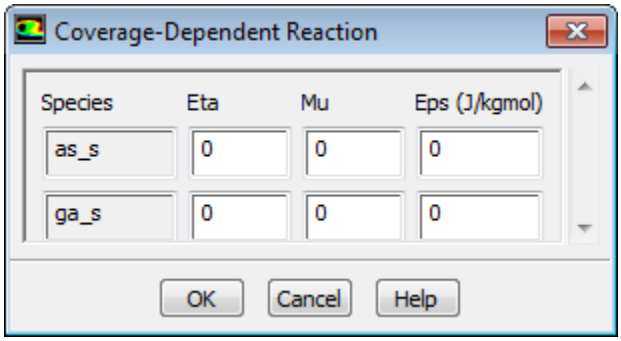
e
is the constant e in Equation 7.22 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.31. Coverage-Dependent Reaction Dialog Box

The **Coverage-Dependent Reaction** dialog box (opened by clicking on **Specify...** under **Coverage-Dependent Reaction** in the Reactions Dialog Box (p. 2334)) allows you to model **Wall Surface** reactions with site-balancing.

(Note that the **Coverage-Dependent Reaction** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)



Controls

Species
are the site species of the reaction.

Eta
is the surface coverage rate modification of the species and is defined in Equation 7.48 in the Theory Guide.

Mu
is the surface coverage rate modification of the species and is defined in Equation 7.48 in the Theory Guide.

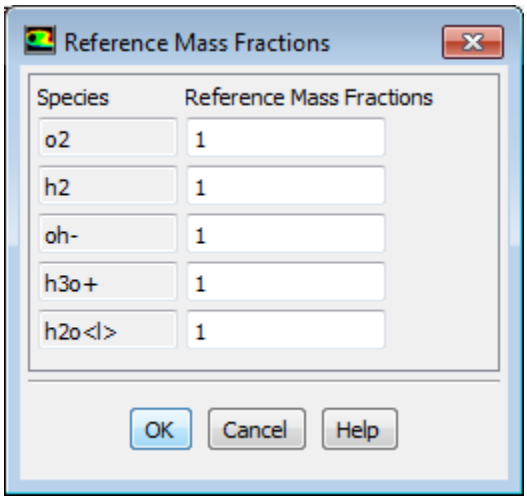
Eps
is the surface coverage rate modification of the species and is defined in Equation 7.48 in the Theory Guide.

37.5.32. Reference Mass Fractions Dialog Box

The **Reference Mass Fractions** dialog box (opened by clicking **Specify Reference Mass Fractions...** under **Butler-Volmer/Tafel Parameters** in the Reactions Dialog Box (p. 2334)) allows you to specify reference species mass fractions for the electrochemical reaction.

(Note that the **Reference Mass Fractions** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Species

are the electrochemical reaction species used in the Butler-Volmer equation (Equation 7.80 in the *Fluent Theory Guide*).

Reference Mass Fractions

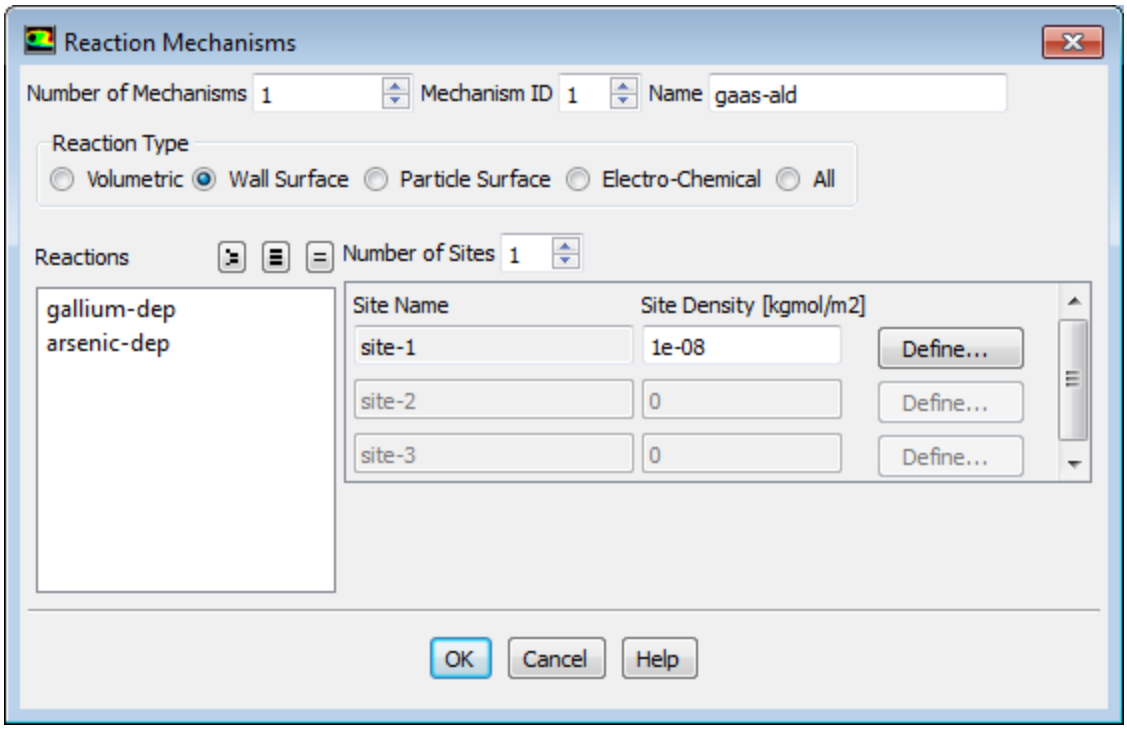
contains inputs for the reference mass fractions of electrochemical reaction species (Y_k in Equation 7.80).

37.5.33. Reaction Mechanisms Dialog Box

The **Reaction Mechanisms** dialog box (opened by clicking the **Edit...** button next to **Mechanism** in the Create/Edit Materials Dialog Box (p. 2302)) allows you to select the reaction mechanism at a particular zone. See Mixture Materials (p. 959) for details about these methods and the related inputs.

(Note that the **Reaction Mechanisms** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of Mechanisms
specifies the number of mechanisms present.

Mechanism ID
is the ID of the mechanism that you specify.

Name
allows you to enter a name for the mechanism.

Reaction Type
specifies the type of reaction to be displayed for the mechanism.

Volumetric
displays all volumetric reactions under the **Reactions** list.

Wall Surface
displays all wall surface reactions under the **Reactions** list.

Particle Surface
displays all particle surface reactions under the **Reactions** list.

Electrochemical
displays all electrochemical reactions under the **Reactions** list.

All
displays all types of reactions under the **Reactions** list.

Reactions
displays the list of reactions of the category specified under **Reaction Type**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Number of Sites
specifies the number of sites at which you can specify the reaction.

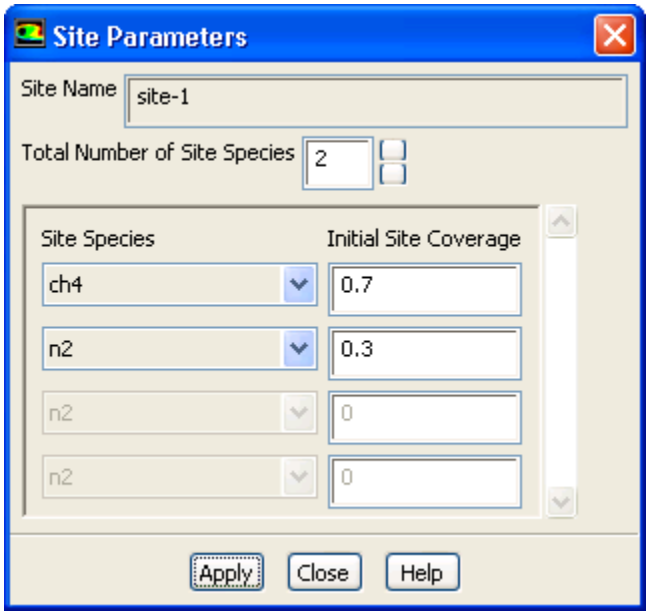
Site Name
contains the name of the site.

Site Density
allows you to specify the site density of the species

Define...
opens the Site Parameters Dialog Box (p. 2344).

37.5.34. Site Parameters Dialog Box

The **Site Parameters** dialog box (opened by clicking the **Define...** button next to **Site Density** in the Reaction Mechanisms Dialog Box (p. 2342)) allows you to define the coverage for each site species.



Controls

Site Name
displays the name of site.

Total Number of Site Species
specifies the total number of site species.

Site Species
allows you to select the site species.

Initial Site Coverage
allows you to specify the initial coverage of the site species.

37.5.35. Mass Diffusion Coefficients Dialog Box

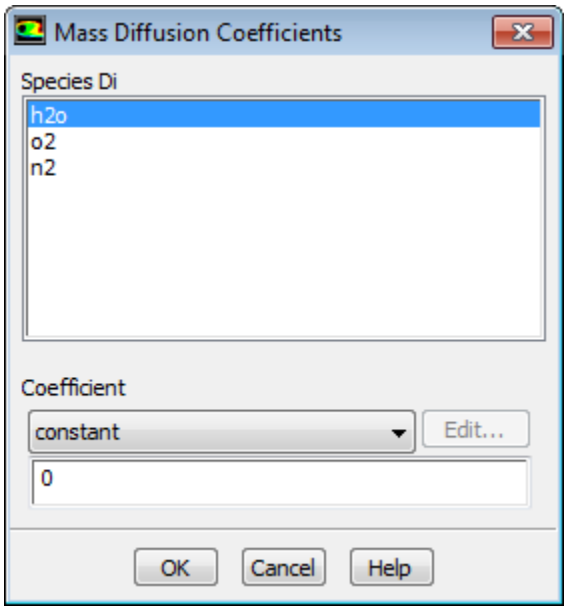
The **Mass Diffusion Coefficients** dialog box (opened by clicking the **Edit...** button next to **Mass Diffusivity** in the Create/Edit Materials Dialog Box (p. 2302) allows you to define the diffusion coefficients of

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the species in the mixture. Its contents will depend on the method you selected for **Mass Diffusivity**. See Mass Diffusion Coefficient Inputs (p. 524) for details about these methods and the related inputs.

(Note that the **Mass Diffusion Coefficients** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

For the **dilute-approx** method:



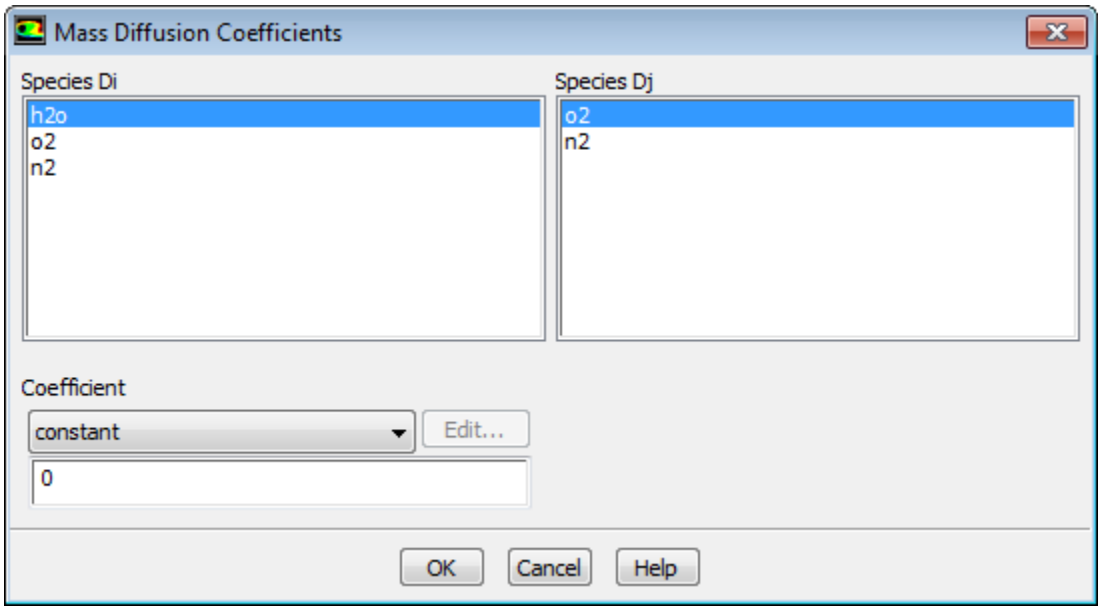
Controls

Species Di
contains a selectable list of all species in the mixture, from which you can select each species and specify its diffusion coefficient.

Coefficient
sets the diffusion coefficient for the selected species in the mixture.

For the **multicomponent** method:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Species Di, Species Dj
contain selectable lists of species in the mixture, from which you can select each pair of species and specify the diffusion coefficient of the selected **Species Di** in the selected **Species Dj**.

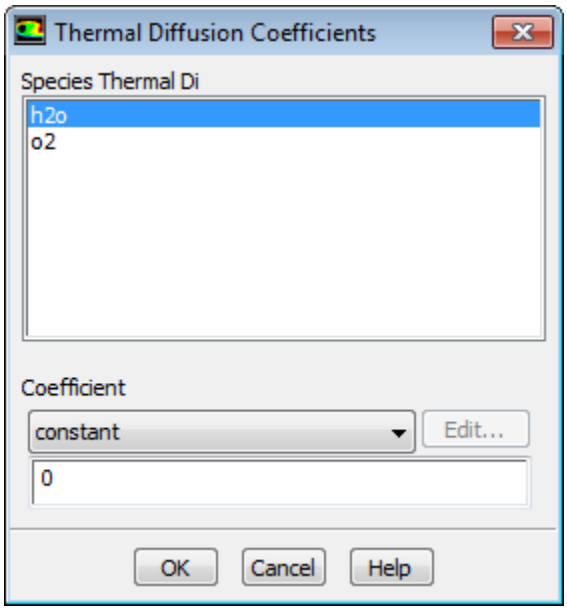
Coefficient
sets the diffusion coefficient for **Species Di** in **Species Dj** (which is equivalent to the diffusion coefficient for **Species Dj** in **Species Di**).

37.5.36. Thermal Diffusion Coefficients Dialog Box

The **Thermal Diffusion Coefficients** dialog box (opened by clicking the **Edit...** button next to **Thermal Diffusion Coefficient** in the Create/Edit Materials Dialog Box (p. 2302) allows you to define the thermal diffusion coefficients of the species in the mixture. See Thermal Diffusion Coefficient Inputs (p. 523) for details about these methods and the related inputs.

(Note that the **Thermal Diffusion Coefficients** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Species Thermal Di
contains a selectable list of all species in the mixture, from which you can select each species and specify its thermal diffusion coefficient.

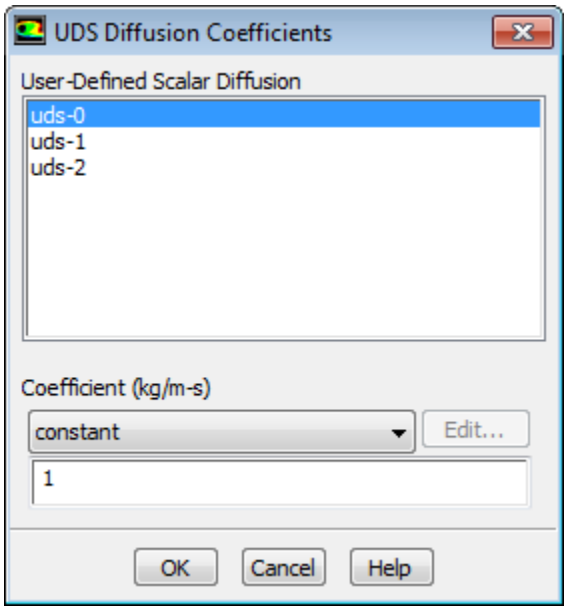
Coefficient
sets the thermal diffusion coefficient for the selected species in the mixture.

37.5.37. UDS Diffusion Coefficients Dialog Box

The **UDS Diffusion Coefficients** dialog box (opened by selecting **uds** and clicking the **Edit...** button next to **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 2302)) allows you to define the diffusion coefficients for your user-defined scalar transport equations.

(Note that the **UDS Diffusion Coefficients** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



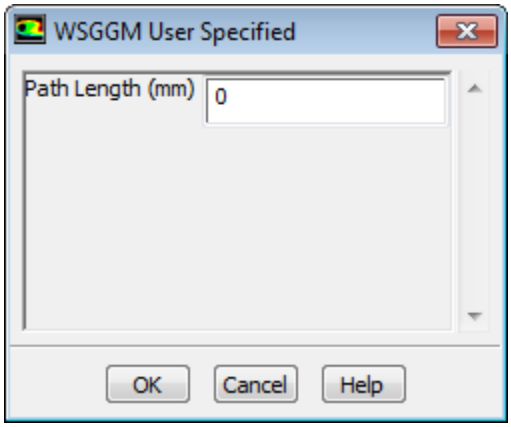
Controls

User-Defined Scalar Diffusion
contains a selectable list of all user-defined scalars, from which you can select each one and specify its diffusion coefficient.

Coefficient
sets the diffusion coefficient for the selected user-defined scalar.

37.5.38. WSGGM User Specified Dialog Box

The **WSGGM User Specified** dialog box opens when you select **wsggm-user-specified** as the input method for a composition-dependent **Absorption Coefficient** in the Create/Edit Materials Dialog Box (p. 2302) and it allows you to define the path length for he weighted-sum-of-gray-gases model. See Inputs for a Composition-Dependent Absorption Coefficient (p. 516) for details.



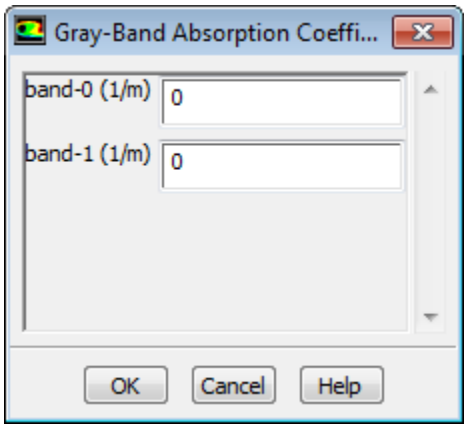
Controls

Path Length
allows you to set the **Path Length** equal to a mean beam length that you have calculated outside of Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.39. Gray-Band Absorption Coefficient Dialog Box

The **Gray-Band Absorption Coefficient** allows you to specify a different absorption coefficient in each gray band when you are modeling non-gray radiation with the P-1, DO, or MC models (see The P-1 Model Equations or The DO Model Equations in the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 847) or Defining Non-Gray Radiation for the DO Model (p. 865)). This dialog box will open when you select **gray-band** in the drop-down list next to **Absorption Coefficient** in the Create/Edit Materials Dialog Box (p. 2302).



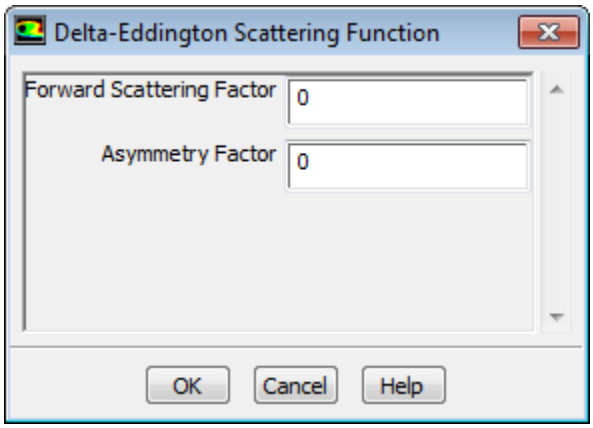
Controls

band n

specifies the absorption coefficient for the n^{th} gray band.

37.5.40. Delta-Eddington Scattering Function Dialog Box

The **Delta-Eddington Scattering Function** dialog box allows you to define the parameters used in the Delta-Eddington phase function for radiation scattering. This dialog box will open when you select **delta-eddington** in the drop-down list next to **Scattering Phase Function** in the Create/Edit Materials Dialog Box (p. 2302). See Anisotropic Scattering for details about the items below.



Controls

Forward Scattering Factor

specifies the value of f in Equation 5.68 in the Theory Guide.

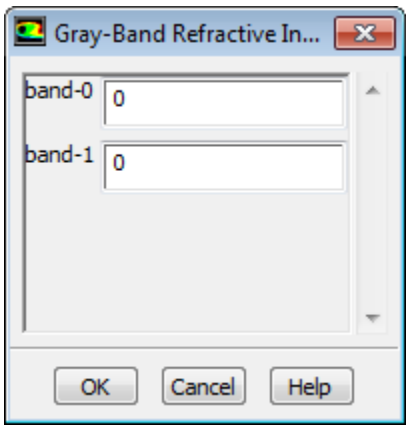
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Asymmetry Factor

specifies the value of C in Equation 5.68 in the Theory Guide.

37.5.41. Gray-Band Refractive Index Dialog Box

The **Gray-Band Refractive Index** allows you to specify a different refractive index in each gray band when you are modeling non-gray radiation with the P-1, DO, or MC model (see The P-1 Model Equations or The DO Model Equations in the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 847) or Defining Non-Gray Radiation for the DO Model (p. 865)). This dialog box will open when you select **refractive-band** in the drop-down list next to **Refractive Index** in the Create/Edit Materials Dialog Box (p. 2302).



Controls

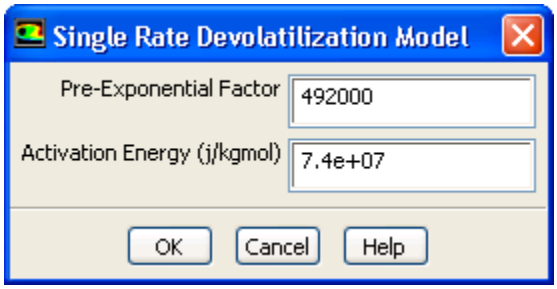
Band n

specifies the refractive index for the n^{th} gray band.

37.5.42. Single Rate Devolatilization Dialog Box

The **Single Rate Devolatilization Model** dialog box (which opens when you select **single-rate** as the **Devolatilization** in the Create/Edit Materials Dialog Box (p. 2302) allows you to specify the parameters used in the single kinetic rate devolatilization model. See Devolatilization (Law 4) in the Theory Guide for details.

Note that the **Single Rate Devolatilization Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.



Controls

Pre-exponential Factor

sets the value of A_1 in Equation 16.128 in the Theory Guide for the computation of the kinetic rate.

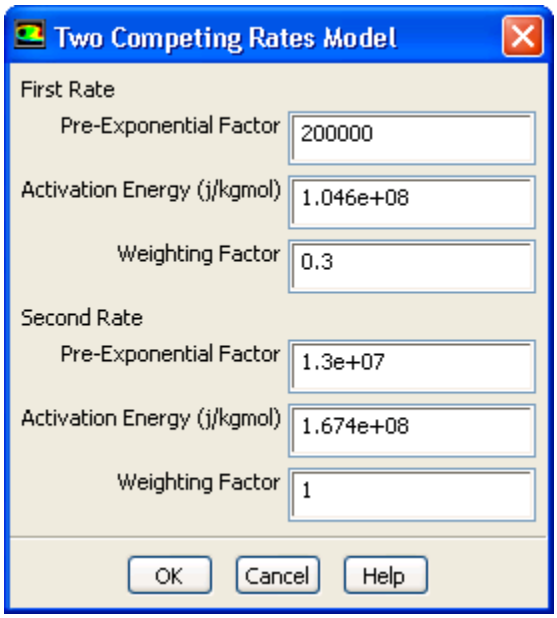
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Activation Energy
sets the value of E in Equation 16.128 in the Theory Guide for the computation of the kinetic rate.

37.5.43. Two Competing Rates Model Dialog Box

The **Two Competing Rates Model** dialog box (which opens when you select **two-competing-rates** as the **Devolatilization Model** in the Create/Edit Materials Dialog Box (p. 2302) allows you to specify the parameters used for each of the competing rates in the two-competing-rates devolatilization model. See Devolatilization (Law 4) in the Theory Guide for details.

Note that the **Two Competing Rates Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.



Controls

First Rate
sets parameters for the first of the two rates.

Pre-exponential Factor
sets the value of A_1 in Equation 16.130 in the Theory Guide for the computation of the kinetic rate.

Activation Energy
sets the value of E_1 in Equation 16.130 in the Theory Guide for the computation of the kinetic rate.

Weighting Factor
sets the value of α_1 in Equation 16.132 in the Theory Guide.

Second Rate
sets parameters for the second of the two rates.

Pre-exponential Factor
sets the value of A_2 in Equation 16.131 in the Theory Guide for the computation of the kinetic rate.

Activation Energy
sets the value of E_2 in Equation 16.131 in the Theory Guide for the computation of the kinetic rate.

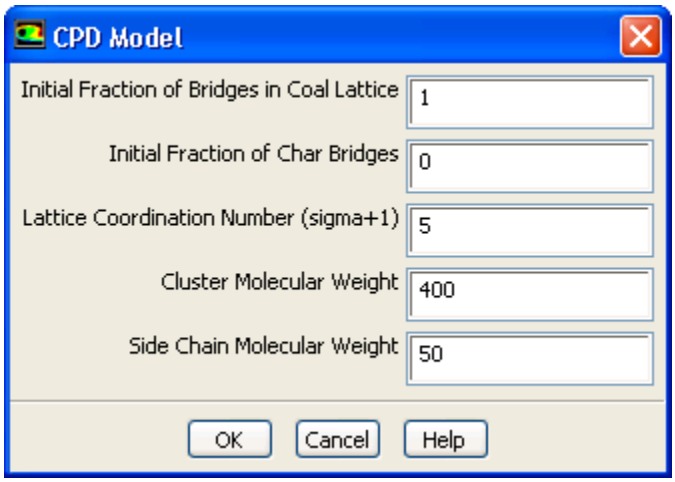
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Weighting Factor
sets the value of α_2 in Equation 16.132 in the Theory Guide.

37.5.44. CPD Model Dialog Box

The **CPD Model** dialog box (which opens when you select **cpd-model** as the **Devolatilization Model** in the Create/Edit Materials Dialog Box (p. 2302)) allows you to specify the parameters used in the CPD devolatilization model. See Devolatilization (Law 4) in the Theory Guide for details.

Note that the **CPD Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.



Controls

Initial Fraction of Bridges in Coal Lattice
sets the value of p_0 in Equation 16.143 in the Theory Guide.

Initial Fraction of Char Bridges
sets the value of c_0 in Equation 16.142 in the Theory Guide.

Lattice Coordination Number
sets the value of $\sigma+1$ in Equation 16.154 in the Theory Guide.

Cluster Molecular Weight
sets the value of $M_{w,1}$ in Equation 16.154 in the Theory Guide.

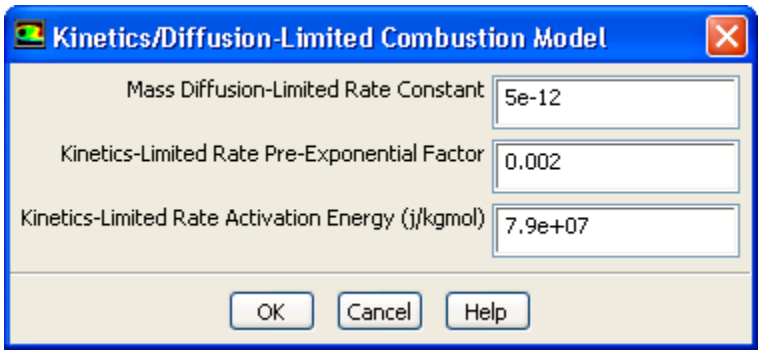
Side Chain Molecular Weight
sets the value of $M_{w,\delta}$ in Equation 16.153 in the Theory Guide.

37.5.45. Kinetics/Diffusion-Limited Combustion Model Dialog Box

The **Kinetics/Diffusion-Limited Combustion Model** dialog box (which opens when you select **kinetics/diffusion-limited** as the **Combustion Model** in the Create/Edit Materials Dialog Box (p. 2302) allows you to specify the parameters used for the kinetics/diffusion-limited rate surface combustion model. See Surface Combustion (Law 5) in the Theory Guide for details.

Note that the **Kinetics/Diffusion-Limited Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Mass Diffusion-Limited Rate Constant
sets the value for C_1 in Equation 16.166 in the Theory Guide.

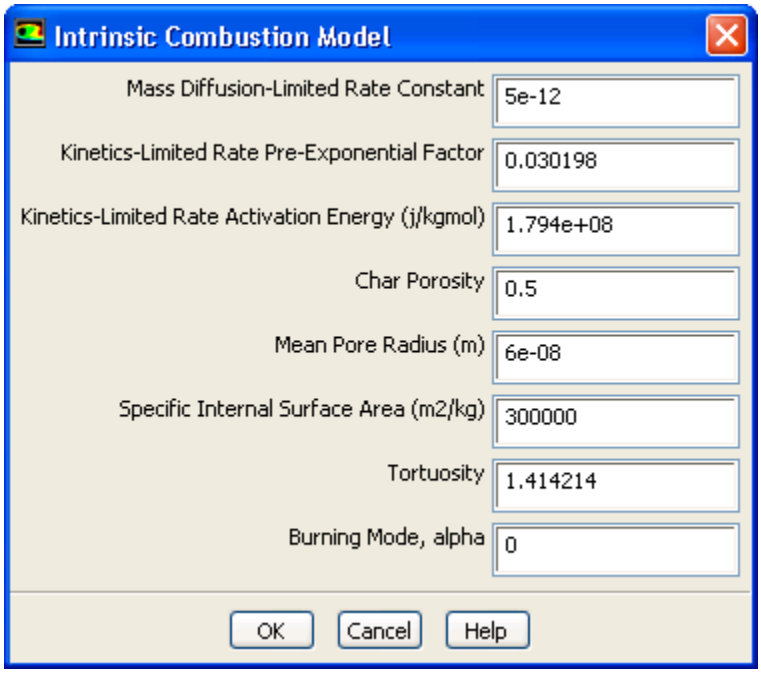
Kinetics-Limited Rate Pre-exponential Factor
sets the value for C_2 in Equation 16.167 in the Theory Guide.

Kinetics-Limited Rate Activation Energy
sets the value for E in Equation 16.167 in the Theory Guide.

37.5.46. Intrinsic Combustion Model Dialog Box

The **Intrinsic Combustion Model** dialog box (which opens when you select **intrinsic-model** as the **Combustion Model** in the Create/Edit Materials Dialog Box (p. 2302) allows you to specify the parameters used for the intrinsic surface combustion model. See Surface Combustion (Law 5) in the Theory Guide for details.

Note that the **Intrinsic Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mass Diffusion-Limited Rate Constant
sets the value for C_1 in Equation 16.166 in the Theory Guide.

Kinetics-Limited Rate Pre-exponential Factor
sets the value for A_i in Equation 16.176 in the Theory Guide.

Kinetics-Limited Rate Activation Energy
sets the value for E_i in Equation 16.176 in the Theory Guide.

Char Porosity
sets the value for θ in Equation 16.173 in the Theory Guide.

Mean Pore Radius
sets the value for $\overline{r}_p$ in Equation 16.175 in the Theory Guide.

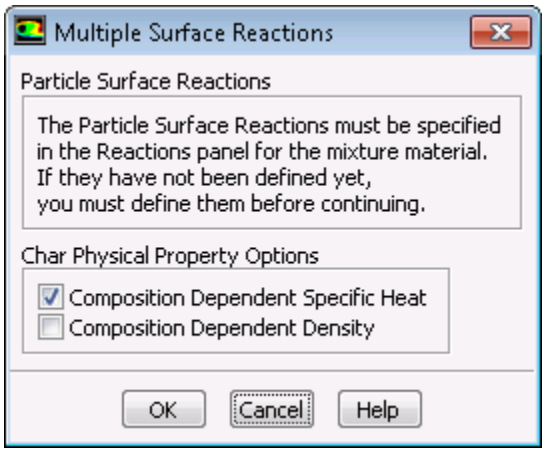
Specific Internal Surface Area
sets the value for A_g in Equation 16.170 and Equation 16.172 in the Theory Guide.

Tortuosity
sets the value for τ in Equation 16.173 in the Theory Guide.

Burning Mode, alpha
sets the value for α in Equation 16.177 in the Theory Guide.

37.5.47. Multiple Surface Reactions Dialog Box

The **Multiple Surface Reactions** dialog box (which opens when you select **multiple-surface-reactions** as the **Combustion Model** in the Create/Edit Materials Dialog Box (p. 2302)) allows you to enable composition-dependent char properties when using the multiple surface reactions combustion model.



Controls

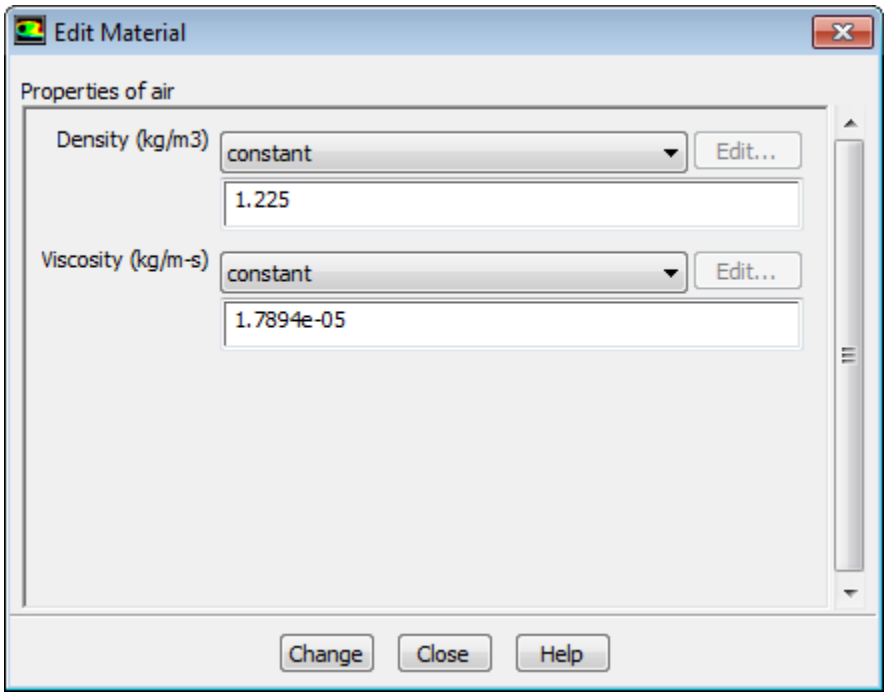
Composition Dependent Specific Heat
enables calculation of the char specific heat from the particle specific heat values. See **Combustion Model** (p. 1319) for details.

Composition Dependent Density
enables calculation of the char density from the particle density values. See **Combustion Model** (p. 1319) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.5.48. Edit Material Dialog Box

The **Edit Material** dialog box contains the portion of the Create/Edit Materials Dialog Box (p. 2302) that contains the properties for a specific material. It is opened from the Primary Phase Dialog Box (p. 2357), Secondary Phase Dialog Box (p. 2357), Wall Dialog Box (p. 2456), Fluid Dialog Box (p. 2369), or Solid Dialog Box (p. 2379).



Controls

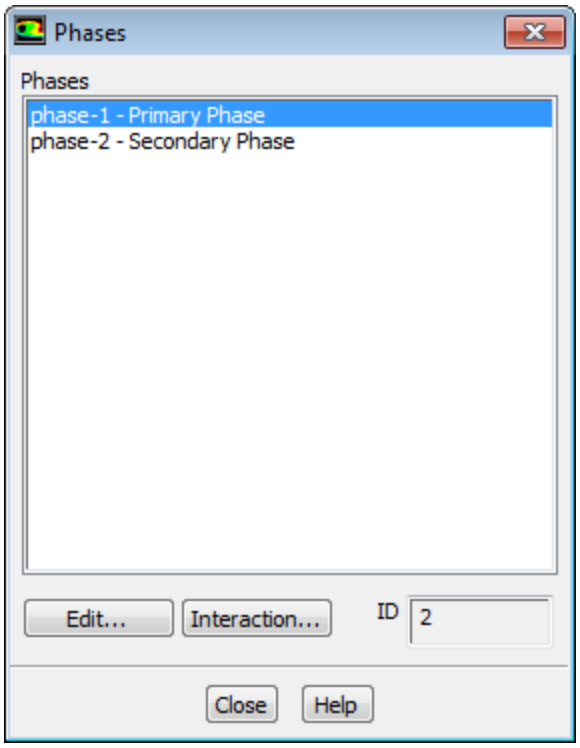
Properties of material-n
contains a list of the properties of material-*n*. The items in the list are the same as those in the Create/Edit Materials Dialog Box (p. 2302).

Change
applies any changes you have made to the properties of the material.

37.6. Phases

The **Phases** dialog box allows you to define each of the phases and the interaction between them. See – Defining the Phases for the Eulerian Model (p. 1456) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Phases

contains a list of all of the phases in the problem from which you can select the phase you want to define or modify. A phase can be a **Primary Phase** or a **Secondary Phase**. You cannot change a phase from primary to secondary, or vice versa. Instead, you can redefine the properties of the primary phase to reflect the new phase designated as primary, and redefine the secondary phases accordingly as well.

Edit...

opens either the Primary Phase Dialog Box (p. 2357) or the Secondary Phase Dialog Box (p. 2357), where you can define the properties of the selected primary or secondary phase.

Interaction...

opens the Phase Interaction Dialog Box (p. 2363), where you can define the interaction between the phases (for example, surface tension if you are using the VOF model, slip velocity functions if you are using the mixture model, or drag functions if you are using the Eulerian model).

ID

displays the ID number of the phase. You will need this number only if you are writing a user-defined function. See the separate Fluent Customization Manual for details about writing user-defined functions for multiphase applications.

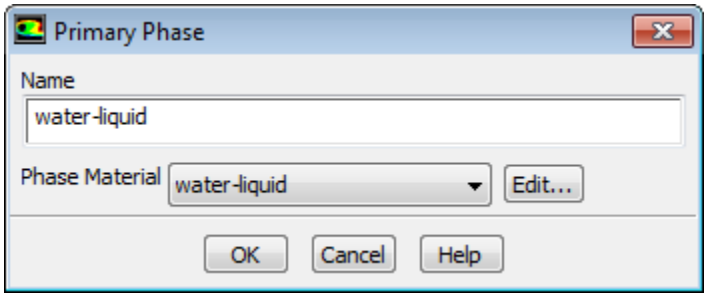
For additional information, see the following sections:

37.6.1. Primary Phase Dialog Box
37.6.2. Secondary Phase Dialog Box
37.6.3. Discrete Phase Dialog Box
37.6.4. Phase Interaction Dialog Box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.6.1. Primary Phase Dialog Box

The **Primary Phase** dialog box allows you to set the properties of the primary phase. It is opened from the Phases (p. 2355). See Defining the Phases for the VOF Model (p. 1436) for details about the items below.



Controls

Name
specifies the name of the phase.

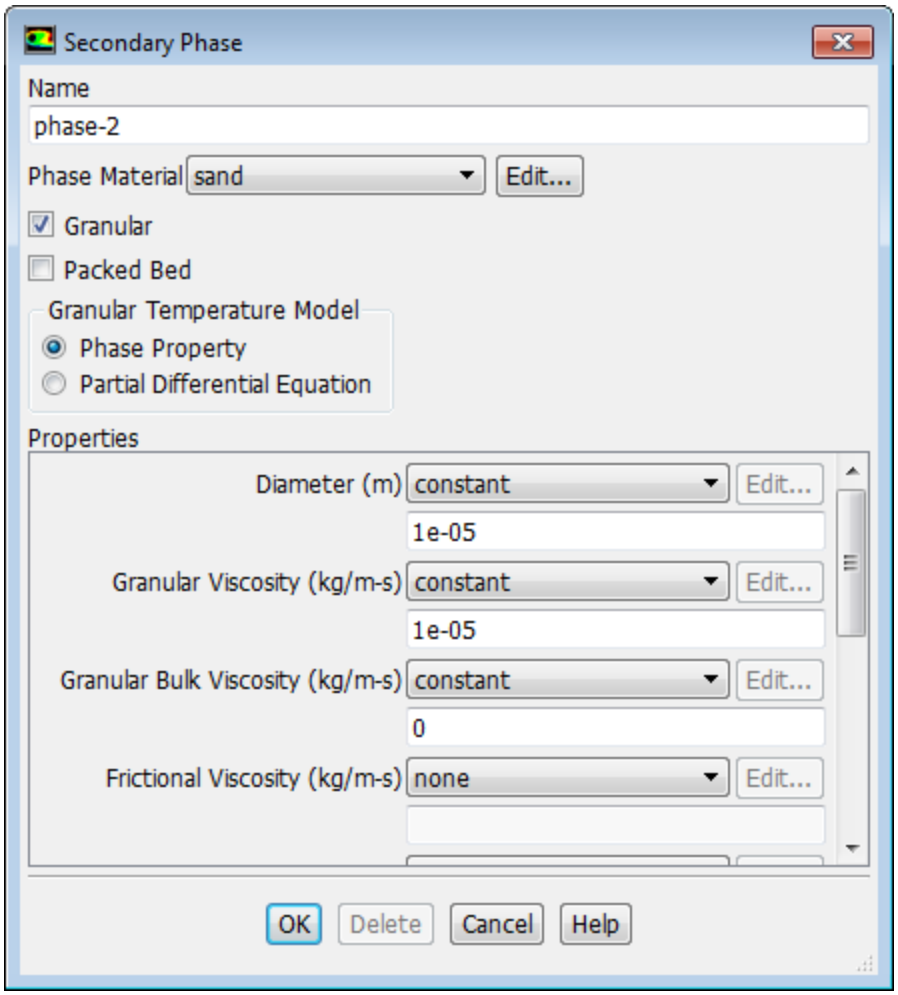
Phase Material
contains a drop-down list of available materials, from which you can select the appropriate one for this phase.

Edit...
opens the Edit Material Dialog Box (p. 2355) for the selected **Phase Material**, where you can modify its properties.

37.6.2. Secondary Phase Dialog Box

The **Secondary Phase** dialog box allows you to set the properties of a secondary phase. It is opened from the Phases (p. 2355). The items that appear in the **Secondary Phase** dialog box will depend on which multiphase model you are using. See Defining the Phases for the VOF Model (p. 1436), Defining the Phases for the Mixture Model (p. 1447), and Defining the Phases for the Eulerian Model (p. 1456) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
specifies the name of the phase.

Phase Material
contains a drop-down list of available materials, from which you can select the appropriate one for the phase.

Edit...
opens the Edit Material Dialog Box (p. 2355) for the selected **Phase Material**, where you can modify its properties.

Granular
indicates whether or not this is a solid phase. This item appears only for the Eulerian model.

Packed Bed
indicates whether or not the granular phase is a packed bed. This option appears only if **Granular** is enabled.

Granular Temperature Model
lists the granular temperature models.

Phase Property
enables phase property model for granular temperature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Partial Differential Equation

enables partial differential equation model for granular temperature. See Granular Temperature in the Theory Guide for details.

Interfacial Area Concentration

is used to predict mass, momentum and energy transfers through the interface between the phases. See Interfacial Area Concentration in the Theory Guide for details.

Properties

contains a list of phase-specific properties. This section of the dialog box will not appear for the VOF model. The **Diameter** appears for both the mixture model and the Eulerian model, but all of the others will appear only for a granular phase with the Eulerian model.

Diameter

specifies the diameter of the particles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the separate Fluent Customization Manual for details about user-defined functions.

Granular Viscosity

specifies the kinetic part of the granular viscosity of the particles ($\mu_{s,kin}$ in Equation 17.307 in the Theory Guide). You can select **constant** (the default) in the drop-down list and specify a constant value, select **syamlal-obrien** to compute the value using Equation 17.309 in the Theory Guide, select **gidaspow** to compute the value using Equation 17.310 in the Theory Guide, or select **user-defined** to use a user-defined function.

Granular Bulk Viscosity

specifies the solids bulk viscosity (λ_q in Equation 17.169 in the Theory Guide). You can select **constant** (the default) in the drop-down list and specify a constant value, select **lun-et-al** to compute the value using Equation 17.311 in the Theory Guide, or select **user-defined** to use a user-defined function.

Frictional Viscosity

specifies a shear viscosity based on the viscous-plastic flow ($\mu_{s,fr}$ in Equation 17.307 in the Theory Guide). By default, the frictional viscosity is neglected, as indicated by the default selection of **none** in the drop-down list. If you want to include the frictional viscosity, you can select **constant** and specify a constant value, select **schaeffer** to compute the value using Equation 17.312 in the Theory Guide, **johnson-et-al**, or select **user-defined** to use a user-defined function.

Angle Of Internal Friction

specifies a constant value for the angle φ used in Schaeffer's expression for frictional viscosity (Equation 17.312 in the Theory Guide). This parameter is relevant only if you have selected **schaeffer**, **johnson-et-al**, or **user-defined** for the **Frictional Viscosity**.

Frictional Pressure

specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johnson-et-al** to apply Equation 17.317 in the Theory Guide, **syamlal-et-al** to apply Equation 17.228 in the Theory Guide, **based-ktgf**, where the frictional pressure is defined by the kinetic theory [26] (p. 2888). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You must hook a user-defined function when selecting the **user-defined** option. See the separate Fluent Customization Manual for information on hooking a UDF.

Frictional Modulus

can be set as **derived**, or as a **user-defined** function. This is defined as Equation 24.9 (p. 1450).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Friction Packing Limit
specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5.

Granular Conductivity
specifies the solids conductivity. You can select **syamlal-obrien**, **gidaspow**, **constant** or **user-defined**.

Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles. You can choose the **algebraic**, **constant**, **dpm-averaged**,or **user-defined** option. **dpm-averaged** is available only when using the Dense Discrete Phase Model (DDPM).

Solids Pressure
specifies the pressure gradient term, ∇p_s, in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, or the **user-defined** option.

Radial Distribution
specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastapour**, or a **user-defined** option.

Elasticity Modulus
is defined as

$$G=\frac{\partial P_s}{\partial \alpha_s} \tag{37.1}$$

with $G \geq 0$.

Choose either the **derived** or **user-defined** options.

Packing Limit
specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres the packing limit is about 0.63, which is the default value in ANSYS Fluent. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

Surface Tension
specifies the attractive forces between the interfaces.

Coalescence Kernel
allows you to specify the coalescence kernel. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim**, and **yao-morel** are described in detail in Interfacial Area Concentration in the Theory Guide.

Breakage Kernel
allows you to specify the breakage kernel. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim**, and **yao-morel** are described in detail in Interfacial Area Concentration in the Theory Guide.

Nucleation Rate
is a source term for the interfacial area concentration that models the rate of formation of the dispersed phase. You can choose from **constant** or **user-defined**. If the **Boiling Model** option is enabled when using the Eulerian multiphase model, you can also select **yao-morel**. The **yao-morel** option is described in Yao-Morel Model in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Critical Weber Number
will need to be specified if you selected **yao-morel** for the **Breakage Kernel**.

Dissipation Function
gives you the option to choose the formula which calculates the dissipation rate used in the **hibiki-ishii** and **ishii-kim** models. You can choose **constant**, **wu-ishii-kim**, **fluent-ke**, and **user-defined** for the dissipation function.

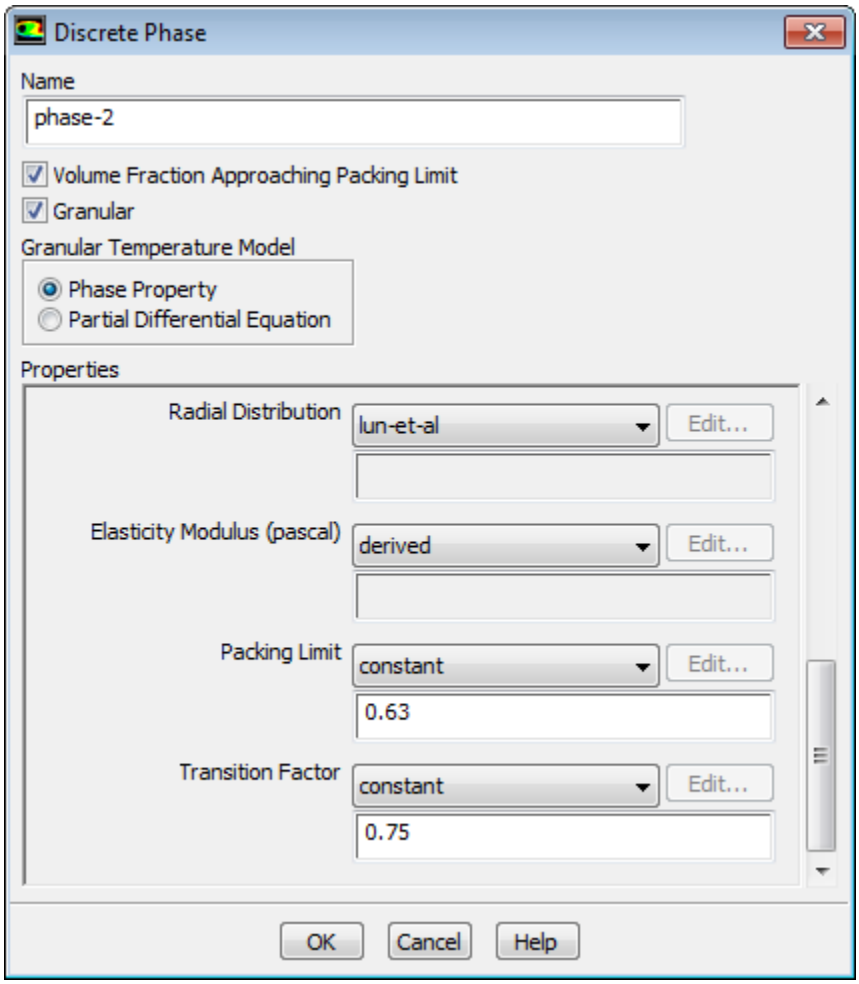
Hydraulic Diameter
is the value used in Equation 24.11 (p. 1453). This is available when the **wu-ishii-kim** formulation is selected as the **Dissipation Function**.

Min/Max Diameter
are the limits of the bubble diameters.

Delete
deletes this phase.

37.6.3. Discrete Phase Dialog Box

The **Discrete Phase** dialog box allows you to set the properties of a discrete phase. It is opened from the Phases (p. 2355). The items will appear in the **Discrete Phase** dialog box when the **Dense Discrete Phase Model** option is enabled in the **Multiphase Model** dialog box. See Including the Dense Discrete Phase Model (p. 1481) for details about the items below.



Controls

Name
specifies the name of the phase.

Volume Fraction Approaching Continuous Flow Limit
appears for non-granular flows. When this option is enabled, only the **Transition Factor** must be specified.

Volume Fraction Approaching Packing Limit
prevents the unlimited accumulation of particles, which are operating at packing limit conditions.

Granular
indicates whether or not this is a solid phase. This item appears only for the Eulerian model.

Granular Temperature Model
lists the granular temperature models.

Phase Property
enables phase property model for granular temperature.

Partial Differential Equation
enables partial differential equation model for granular temperature. See Granular Temperature in the Theory Guide for details.

Properties
contains a list of phase-specific properties.

Granular Viscosity
specifies the kinetic part of the granular viscosity of the particles ($\mu_{s,kin}$ in Equation 17.307 in the Theory Guide). You can select **constant** (the default) in the drop-down list and specify a constant value, select **syamlal-obrien** to compute the value using Equation 17.309 in the Theory Guide, select **gidaspow** to compute the value using Equation 17.310 in the Theory Guide, or select **user-defined** to use a user-defined function.

Granular Bulk Viscosity
specifies the solids bulk viscosity (λ_q in Equation 17.169 in the Theory Guide). You can select **constant** (the default) in the drop-down list and specify a constant value, select **lun-et-al** to compute the value using Equation 17.311 in the Theory Guide, or select **user-defined** to use a user-defined function.

Frictional Viscosity
specifies a shear viscosity based on the viscous-plastic flow ($\mu_{s,fr}$ in Equation 17.307 in the Theory Guide). By default, the frictional viscosity is neglected, as indicated by the default selection of **none** in the drop-down list. If you want to include the frictional viscosity, you can select **constant** and specify a constant value, select **schaeffer** to compute the value using Equation 17.312 in the Theory Guide, **johnson-et-al**, or select **user-defined** to use a user-defined function.

Angle Of Internal Friction
specifies a constant value for the angle φ used in Schaeffer's expression for frictional viscosity (Equation 17.312 in the Theory Guide). This parameter is relevant only if you have selected **schaeffer**, **johnson-et-al**, or **user-defined** for the **Frictional Viscosity**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Frictional Pressure

specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johnson-et-al** to apply Equation 17.317 in the Theory Guide, **syamlal-obrien** to apply Equation 17.228 in the Theory Guide, **based-ktgf**, where the frictional pressure is defined by the kinetic theory [26] (p. 2888). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You must hook a user-defined function when selecting the **user-defined** option. See the separate Fluent Customization Manual for information on hooking a UDF.

Frictional Modulus

can be set as **derived**, or as a **user-defined** function. This is defined as Equation 24.9 (p. 1450).

Friction Packing Limit

specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5.

Granular Conductivity

specifies the solids conductivity. You can select **syamlal-obrien**, **gidaspow**,or **user-defined**.

Solids Pressure

specifies the pressure gradient term, ∇p_s, in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, or the **user-defined** option.

Radial Distribution

specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastapour**, or a **user-defined** option.

Elasticity Modulus

is defined as

$$G=\frac{\partial P_s}{\partial \alpha_s} \tag{37.2}$$

with $G \geq 0$.

Choose either the **derived** or **user-defined** options.

Packing Limit

specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres the packing limit is about 0.63, which is the default value in ANSYS Fluent. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

Transition Factor

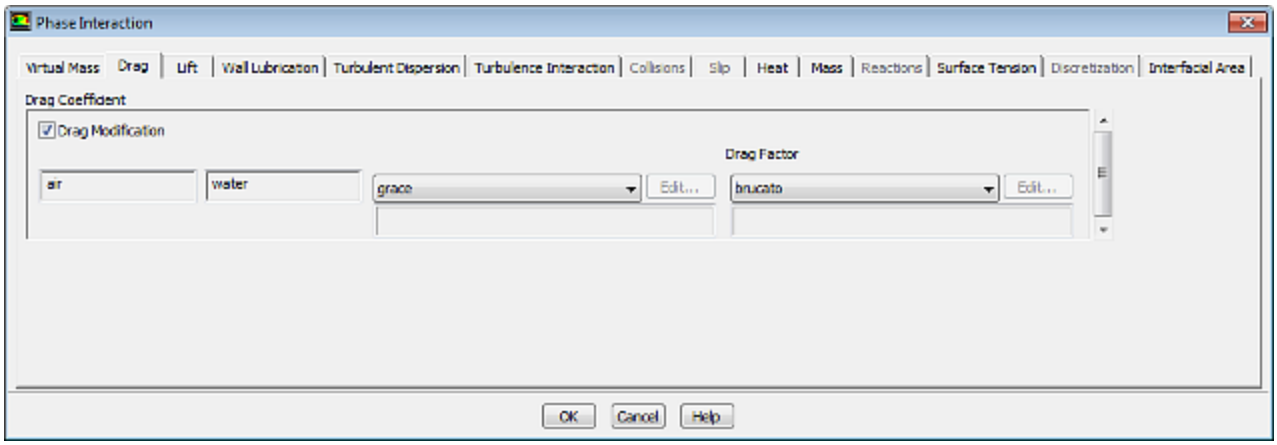
is specified as either a **constant** or a **user-defined** function. The default value is assumed to be 0.75, which corresponds to the closest sphere packing for monosized spheres (a factor of 4/3). In other words, the transition criterion is based on the local particle volume fraction of the given discrete phase and is specified as a factor multiplied by the maximum packing limit (also a user specified value).

37.6.4. Phase Interaction Dialog Box

The **Phase Interaction** dialog box allows you to define the interaction between phases. It is opened from the Phases (p. 2355). The items that appear in the **Phase Interaction** dialog box will depend on

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

which multiphase model you are using. See Defining the Phases for the VOF Model (p. 1436), Defining the Phases for the Mixture Model (p. 1447), and Defining the Phases for the Eulerian Model (p. 1456) for details about the items below.



Controls

Virtual Mass

displays the Virtual Mass Coefficient inputs. This tab is active only for the Eulerian models.

Virtual Mass Modeling

includes the "virtual mass force" (F_{vm} in Equation 17.288 in the Theory Guide) that is present when a secondary phase accelerates relative to the primary phase.

Implicit

enables the implicit method for the virtual mass force which can improve convergence in some cases.

Virtual Mass Implicit Options

specifies what form of the implicit method to use. **Default** models the entire virtual mass force while **Option 2** and **Option 3** model truncated expressions which may further improve convergence.

Virtual Mass Coefficient

specifies the virtual mass coefficient for each pair of phases. See Including the Virtual Mass Force (p. 1474) for details.

Drag

displays the **Drag Coefficient** inputs. This tab is active only for the Eulerian and mixture models.

Drag Coefficient

specifies the drag function for each pair of phases. This section of the dialog box appears only for the Eulerian and mixture models. See Defining the Phases for the Eulerian Model (p. 1456) for information about the available options.

Drag Modification

enables modification of the selected drag models by a drag factor and expands the dialog box to show the **Drag Factor** settings. See Drag Modification (p. 1466) for additional information on using Drag Modification.

Drag Factor

specifies the drag factor to use for modifying the specified drag model. See Drag Modification (p. 1466) for additional information on specifying the **Drag Factor**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lift

displays the **Lift Coefficient** inputs. This tab is active only for the Eulerian model.

Lift Coefficient

specifies the lift function for each pair of phases. This section of the dialog box appears only for the Eulerian model. See Defining the Phases for the Eulerian Model (p. 1456) for information about the available options.

Wall Lubrication

displays the **Wall Lubrication** inputs. This tab is active only for the Eulerian model.

Wall Lubrication

specifies the wall lubrication model for each primary-secondary phase pair. This section of the dialog box appears only for the Eulerian model. See Including the Wall Lubrication Force (p. 1467) for information about the available options.

Turbulent Dispersion

displays the **Turbulent Dispersion** inputs. This tab is active only for the Eulerian model.

Turbulent Dispersion

specifies the turbulent dispersion model for each primary-secondary phase pair. This section of the dialog box appears only for the Eulerian model. See Including the Turbulent Dispersion Force (p. 1470) for information about the available options.

Turbulence Interaction

displays the **Turbulence Interaction** inputs. This tab is active only for the Eulerian model.

Turbulence Interaction

specifies the turbulence interaction model for each primary-secondary phase pair. This section of the dialog box appears only for the Eulerian model. See Including Turbulence Interaction Source Terms (p. 1476) for information about the available options.

Collisions

displays the **Restitution Coefficient** inputs.

Restitution Coefficient

specifies the restitution coefficient for collisions between each pair of granular phases, and for collisions between particles of the same granular phase. It is relevant only if two or more granular phases are involved. See Defining the Phases for the Eulerian Model (p. 1456) for information about the available options.

Slip

displays the **Slip Velocity** inputs. This tab is active only for the mixture model.

Slip Velocity

specifies the slip velocity function for each secondary phase with respect to the primary phase. See Defining the Phases for the Mixture Model (p. 1447) for information about the available options.

Heat

displays the **Heat Transfer Coefficient** inputs. This tab is active only for the Eulerian model when the energy equation is active.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Heat Transfer Coefficient
specifies the heat transfer coefficient function between each pair of phases. See Including Heat Transfer Effects (p. 1478) for information about the available options.

Mass
displays the **Mass Transfer Function** inputs.

Number of Mass Transfer Mechanisms
specifies the number of mass transfer mechanisms in your simulation. See Including Mass Transfer Effects (p. 1383) for information about the available options.

Reactions
allows you to define multiple heterogeneous reactions and stoichiometry.

Total Number of Heterogeneous Reactions
specifies the total number of reactions (volumetric reactions, wall surface reactions, and particle surface reactions). See Specifying Heterogeneous Reactions (p. 1380) for information about the available options.

Heterogeneous Stiff Chemistry Solver
is used in inter-phase reaction mechanisms containing numerically stiff reactions. This option can improve convergence and is available for transient Eulerian multiphase simulations.

Reaction Name
allows you to enter a name for the reaction.

ID
enables you to set the reaction ID for each reaction.

Number of Reactants
allows you to specify the number of reactants that are involved in the reaction.

Number of Products
allows you to specify the number of products that are involved in the reaction.

Phase
drop-down list allows you to select the phase that is involved in the reaction.

Species
drop-down list allows you to select the species.

Stoich. Coefficient
allows you to set the stoichiometric coefficient.

Reaction Rate Function
allows you to choose rate exponents for an Arrhenius-type reaction, a user-defined function, or a population balance mechanism for the reaction rate.

Surface Tension
includes the effects of surface tension along the fluid-fluid interface.

Model
contains two surface tension models from which to choose.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Continuum Surface Force
adds the surface tension to the VOF calculation, which results in a source term in the momentum equation. This method is available only for the VOF and Eulerian models.

Continuum Surface Stress
is an alternative way to modeling surface tension in a conservative manner compared to the continuum surface force method. This method is available only for the VOF and Eulerian models.

Adhesion Options
contains options to include wall and jump adhesion.

Wall Adhesion
enables the specification of a wall adhesion angle. (The angle itself, as defined in Figure 24.31: Measuring the Contact Angle (p. 1442), will be specified in the Wall Dialog Box (p. 2456).) This item will appear only for the VOF and Eulerian models.

Jump Adhesion
enables the treatment of the contact angle specification at the porous jump boundary. (The angle itself will be specified in the Porous Jump Dialog Box (p. 2427).)

Surface Tension Coefficients
specify the surface tension coefficient, σ in Equation 17.22 and Equation 16.80 in the Theory Guide, for each pair of phases. See Defining the Phases for the VOF Model (p. 1436) for details.

Discretization
allows you to use the diffusive and anti-diffusive discretization procedure across the distinct interfaces.

Phase Localized Compressive Scheme
enables the compressive discretization scheme in ANSYS Fluent, where the degree of diffusion/sharpness is controlled through the value of the slope limiters. This item will appear only for the VOF model and for the Eulerian model with **Multi-Fluid VOF Model** enabled.

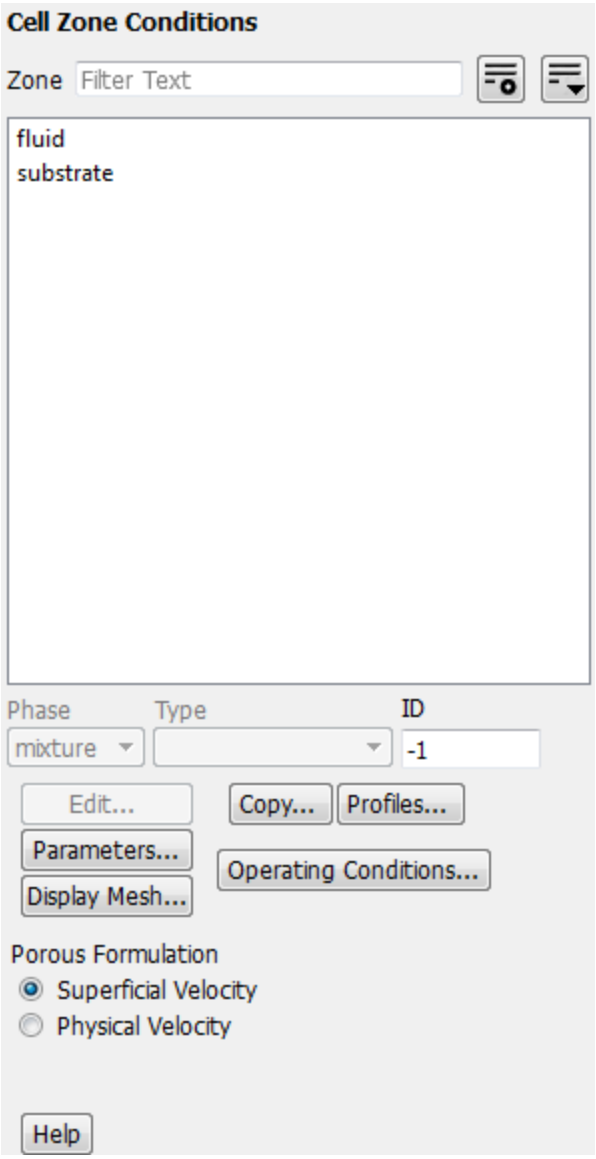
Slope Limiters
are values equating to specific discretization schemes. For each pair of phases, you can enter a value of 0, 1, or 2, or any value between 0 and 2. Depending on the value you use, first order upwind, second order upwind, compressive, or the blended scheme will be applied. Refer to Table 24.11: Slope Limiter Discretization Scheme (p. 1444) to equate each value of the slope limiter with a discretization scheme. For more information, refer to Discretizing Using the Phase Localized Compressive Scheme (p. 1443).

Interfacial Area
displays the **Interfacial Area** inputs. This tab only appears for the Eulerian Model. See Using an Algebraic Interfacial Area Model (p. 1480) and Interfacial Area Concentration in the *Fluent Theory Guide* for information about the available options.

37.7. Cell Zone Conditions Task Page

The **Cell Zones Conditions** task page allows you to set the type of a cell zone and display other dialog boxes to set the cell zone condition parameters for each zone. See Cell Zone Conditions (p. 252) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone

contains a selectable list of available cell zones from which you can select the zone of interest. You can check a zone type by using the mouse probe (see Controlling the Mouse Button Functions (p. 1800)) on the displayed physical mesh. This feature is particularly useful if you are setting up a problem for the first time, or if you have two or more cell zones of the same type and you want to determine the cell zone IDs. To do this you must first display the mesh with the Mesh Display Dialog Box (p. 2163). Then click the boundary zone with the right (select) mouse button. ANSYS Fluent will print the cell zone ID and type of that boundary zone in the console window.

Phase

specifies the phase for which conditions at the selected cell **Zone** are being set. This item appears if the VOF, mixture, or Eulerian multiphase model is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Type

contains a drop-down list of condition types for the selected cell zone. The list contains all possible types to which the cell zone can be changed.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ID
displays the cell zone ID number of the selected cell zone. (This is for informational purposes only; you cannot edit this number.)

Edit...
opens the Fluid Dialog Box (p. 2369) or Solid Dialog Box (p. 2379).

Copy...
opens the Copy Conditions Dialog Box (p. 2381), which allows you to copy conditions from one cell zone to other cell zones of the same type. See Copying Cell Zone and Boundary Conditions (p. 242) for details.

Profiles...
opens the Profiles Dialog Box (p. 2385).

Parameters...
opens the Parameters Dialog Box (p. 2627).

Operating Conditions...
opens the Operating Conditions Dialog Box (p. 2382).

Display Mesh...
opens the Mesh Display Dialog Box (p. 2163).

Porous Formulation
contains options for setting the velocity in the porous medium simulation. See Defining the Porous Velocity Formulation (p. 269) for details.

Superficial Velocity
enables the superficial velocity in a porous medium simulation. This is the default method.

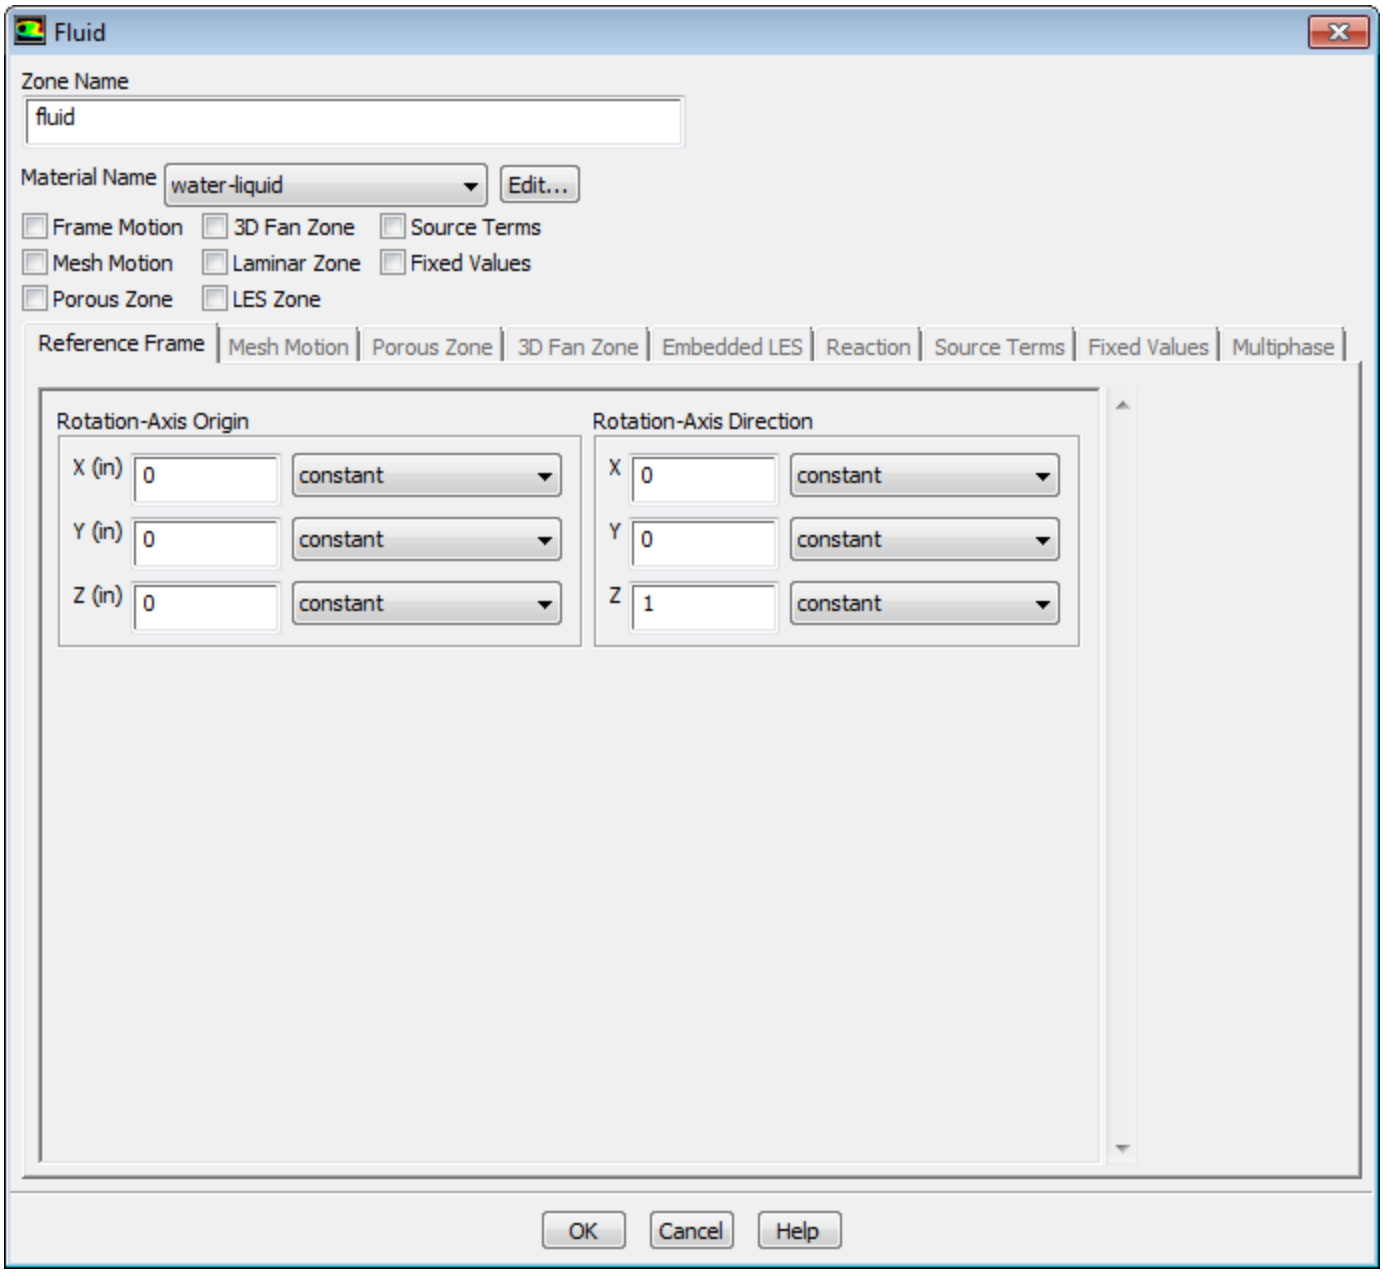
Physical Velocity
enables the physical velocity in a porous medium simulation for a more accurate simulation. This option is available only for a pressure-based solver. See Modeling Porous Media Based on Physical Velocity (p. 283) for details.

For additional information, see the following sections:
37.7.1. Fluid Dialog Box
37.7.2. Solid Dialog Box
37.7.3. Copy Conditions Dialog Box
37.7.4. Operating Conditions Dialog Box
37.7.5. Select Input Parameter Dialog Box
37.7.6. Profiles Dialog Box
37.7.7. Orient Profile Dialog Box
37.7.8. Write Profile Dialog Box

37.7.1. Fluid Dialog Box

The **Fluid** dialog box sets the conditions for a fluid cell zone. It is opened from the Cell Zone Conditions Task Page (p. 2367). See Inputs for Fluid Zones (p. 253) and User Inputs for Porous Media (p. 267) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name

sets the name of the zone.

Material Name

sets the fluid material. The drop-down list contains the names of all materials that have been loaded into the solver. Materials are defined with the Materials Task Page (p. 2300).

Important

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid zones will be the material you specified in the Species Model Dialog Box (p. 2216). For

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

multiphase flows, the materials are specified when you define the phases, as described in Defining the Phases for the VOF Model (p. 1436).

Frame Motion
enables the moving reference frame model for the cell zone. See Specifying the Rotation Axis (p. 255) and Defining Zone Motion (p. 256) for details.

Mesh Motion
enables the sliding mesh model for the cell zone. See Setting Up the Sliding Mesh Problem (p. 634) for details.

Porous Zone
indicates that the zone is a porous medium. Additional items will appear in the dialog box when this option is enabled. See User Inputs for Porous Media (p. 267) for details.

3D Fan Zone
allows you to simulate the effect of an axial fan by applying a distributed momentum source in a toroid-shaped fluid volume. This model can calculate not only the axial velocity, but the swirl and radial velocities as well. When you enable this option, the **3D Fan Zone** tab becomes available, so that you can specify the geometry and properties of the fan. The cell zone should have a toroid shape that is sized to match the blade-swept volume of the fan you are simulating (that is, has an inner and outer radius that matches the radius of the fan's hub and blade tips, respectively, as well as a length that matches the thickness of the toroid region swept by the blades in the axial direction). Furthermore, the fluid cell zone should be "interior", that is, have at least two boundary zones of type **interior** that border another fluid cell zone and act as the fan inlet and outlet (the other boundaries can be of type **interior** as well). See 3D Fan Zones (p. 287) for details.

Laminar Zone
disables the calculation of turbulence production in the fluid zone (appears only for turbulent flow calculations using the Spalart-Allmaras model or one of the k- ε or k- ω models). See Specifying a Laminar Zone (p. 255) for details.

LES Zone
allows you to model a smaller embedded LES zone within a larger URANS computational domain for turbulent flow calculations. When you turn on this option, the **Embedded LES** tab will be enabled to allow you to specify properties for the embedded LES zone. See Setting Up the Embedded Large Eddy Simulation (ELES) Model (p. 793) for details.

Source Terms
enables the specification of volumetric sources of mass, momentum, energy, and so on. When you turn on this option, the **Source Terms** tab will be enabled to allow you to specify the values for the desired sources. See Defining Mass, Momentum, Energy, and Other Sources (p. 297) for details.

Fixed Values
enables the fixing of the value of one or more variables in the fluid zone, rather than computing them during the calculation. See Fixing the Values of Variables (p. 292) for details.

Important

You can fix values for velocity components, temperature, and species mass fractions only if you are using the pressure-based solver.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Participates In Radiation
specifies whether or not the fluid zone participates in radiation. This option appears when you are using the DO model for radiation.

> **Warning**
>
> In general, disabling **Participates in Radiation** for fluid zones is not recommended, as it can produce erroneous results. There are rare cases when it is acceptable: for example, if the domain contains multiple fluid zones, disabling this option for zones where radiation is negligible may save computational time without affecting the results.

Reaction
enables/disables reactions in the porous zone.

Electrolyte
indicates that the zone is an electrolyte zone. By default, all fluid zones are assumed to be electrolyte zones. This option appears when the **Electrochemical** Reaction model is enabled.

Reference Frame
lists the parameters that define motion for a moving reference frame.

Rotation-Axis Origin
specifies the origin for the axis of rotation of solid zone. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D and 2D non-axisymmetric models.

Rotation-Axis Direction
specifies the direction vector for the solid zone's axis of rotation. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D models.

Rotational Velocity
contains an input field for the rotational **Speed** of the zone.

Translational Velocity
contains inputs for the **X**, **Y**, and **Z** velocities of the zone.

Relative Specification
indicates whether the velocities are absolute velocities (**absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

UDF
allows you to hook the DEFINE_ZONE_MOTION user-defined function.

Copy to Mesh Motion
allows you to switch between the MRF and moving mesh models. The variables used for the origin, axis, and velocity components, as well as for the `DEFINE_ZONE_MOTION` user-defined function, will be copied from one model to the other.

Mesh Motion
lists the parameters that define motion for a moving reference frame.

Rotation-Axis Origin
specifies the origin for the axis of rotation of solid zone. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D and 2D non-axisymmetric models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rotation-Axis Direction
specifies the direction vector for the solid zone's axis of rotation. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D models.

Rotational Velocity
contains an input field for the rotational **Speed** of the zone.

Translational Velocity
contains inputs for the **X**, **Y**, and **Z** velocities of the zone.

Relative Specification
indicates whether the velocities are absolute velocities (**absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

UDF
allows you to hook the DEFINE_ZONE_MOTION user-defined function.

Copy to Frame Motion
allows you to switch between the MRF and moving mesh models. The variables used for the origin, axis, and velocity components, as well as for the `DEFINE_ZONE_MOTION` user-defined function, will be copied from one model to the other.

Porous Zone
lists the parameters associated with the porous zone.

Conical
enables the specification of a conical (or cylindrical) porous medium. This item will appear only when the **Porous Zone** option is enabled for a 3D case.

Cone Half Angle
specifies the angle between the cone's axis and its surface (see Figure 6.13: Cone Half Angle (p. 271)). Set this to 0 to define the porous region using a cylindrical coordinate system. This item will appear only when the **Porous Zone** and **Conical** options are enabled.

Snap to Zone
aligns the plane (or line, in 2D) tool with the zone selected in the drop-down list. The tool is centered at the centroid of the zone, with the tool's axis normal to the zone. If this axis is not the desired cone axis, reposition the tool (as described in Using the Plane Tool (p. 1724)). When you are satisfied with the axis, click the **Update From Plane Tool** (or **Update From Line Tool**) button to update the **Cone Axis Vector** fields.

This item will appear only when the **Porous Zone** and **Conical** options are enabled.

Update From Plane Tool
(**Update From Line Tool** in 2D) updates the **Direction-1 Vector** and (in 3D) the **Direction-2 Vector** from the plane tool orientation. If the **Conical** option is enabled, this button will update the **Cone Axis Vector** and the **Point on Cone Axis**. See Defining the Viscous and Inertial Resistance Coefficients (p. 270) for details. This item will appear only when the **Porous Zone** option is enabled.

Direction-1 Vector, Direction-2 Vector
indicate the directions for which the resistance coefficients are defined. See Defining the Viscous and Inertial Resistance Coefficients (p. 270) for details. These items will appear only when the **Porous Zone** option is enabled, but the **Conical** option is not. (In 2D, only **Direction-1 Vector** will appear.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cone Axis Vector
specifies the **X,Y,Z** vector for the cone's axis.

This item will appear only when the **Porous Zone** and **Conical** options are enabled.

Point on Cone Axis
specifies a point on the cone's axis. This point will be used by ANSYS Fluent to transform the resistances to the Cartesian coordinate system.

This item will appear only when the **Porous Zone** and **Conical** options are enabled.

Relative Velocity Resistance Formulation
allows ANSYS Fluent to either apply the relative reference frame or the absolute reference frame. This allows for the correct prediction of the source terms.

Viscous Resistance, Inertial Resistance
contain inputs for the viscous resistance coefficient $1/\alpha$ and the inertial resistance coefficient $C2$ in each direction. See Defining the Viscous and Inertial Resistance Coefficients (p. 270) for details. These items will appear only when the **Porous Zone** option is enabled.

Alternative Formulation
provides better stability to the calculation when your porous medium is anisotropic.

If you have enabled the **Conical** option, **Direction-1** is the cone axis direction, **Direction-2** is the normal to the cone surface (radial (r) direction for a cylinder), and **Direction-3** is the circumferential (θ) direction.

Power Law Model
contains inputs for the **C0** and **C1** coefficients in the power law model for porous media. See Using the Power-Law Model (p. 276) for details.

Fluid Porosity
contains an additional input for the porous medium. See User Inputs for Porous Media (p. 267) for details.

Porosity
sets the volume fraction of fluid within the porous region.

Heat Transfer Settings
contains heat transfer settings for the porous medium. See Specifying the Heat Transfer Settings (p. 277) for details.

Thermal Model
specifies whether or not thermal equilibrium is assumed between the medium and the fluid flow.

Equilibrium
specifies that the medium and the fluid flow are in thermal equilibrium in the porous medium.

Non-Equilibrium
specifies that the medium and the fluid flow are not in thermal equilibrium in the porous medium, so that a dual cell approach is enabled.

Solid Material Name
specifies the solid material in the porous region. This drop-down menu is only available when **Equilibrium** is selected from the **Thermal Model** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solid Zone
displays the name of the solid cell zone that is coupled with the porous fluid zone through heat transfer. This field is only displayed when **Non-Equilibrium** is selected from the **Thermal Model** list.

Interfacial Area Density
specifies A_{fs} (as described in Non-Equilibrium Thermal Model Equations (p. 265)) for the porous region. This text-entry box is only available when **Non-Equilibrium** is selected from the **Thermal Model** list.

Heat Transfer Coefficient
specifies h_{fs} (as described in Non-Equilibrium Thermal Model Equations (p. 265)) for the porous region. This text-entry box is only available when **Non-Equilibrium** is selected from the **Thermal Model** list.

Anisotropic Species Diffusion
allows you to model anisotropic species diffusion in porous media. When this option is selected, you can specify the **Matrix Components** for the anisotropic diffusion matrix in the porous zone. This option is available only with the species transport models.

3D Fan Zone
provides the settings that define a 3D fan zone. See 3D Fan Zones (p. 287) for details.

Geometry
allows you to define the location and size of the fan.

Inlet Fan Zone
allows you to select a boundary zone of type **interior** that will act as the surface on which the fan will be located.

Hub Radius
defines the radius of the fan hub, that is, the inner radius of the blade-swept volume on which the fan's distributed momentum sources are applied.

Tip Radius
defines the radius of the blade tips of the fan, that is, the outer radius of the blade-swept volume on which the fan's distributed momentum sources are applied.

Thickness
defines the thickness of the toroid region swept by the blades in the axial direction.

Inflection Point
is a ratio that defines the fraction of the fan blade length (starting at the hub) over which the tangential velocity of the fan discharge is increasing with increasing radius and peaks, before tapering off (see Figure 6.17: The Inflection Point Ratio of a Pitched Blade Turbine (p. 291)).

Fan Origin
defines the **X**, **Y**, and **Z** coordinates of a point on the **Inlet Fan Zone** that is the origin for the fan.

Properties
allows you to define how the fan behaves.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rotational Direction
allows you to define the fan's rotational direction, using the right-hand rule with respect to the fan direction vector (that is, a vector from the **Fan Origin** that points into the 3D fan zone perpendicular to the **Inlet Fan Zone**).

Operating Angular Velocity
defines the angular velocity of the fan during the simulation.

Limit Flow Rate Through Fan
specifies that the flow rate through the fan adheres to minimum and maximum values, as defined in the **Flow Rate** group box.

Flow Rate
allows you to define the **Maximum** and **Minimum** flow rates through the fan. This group box is available when the **Limit Flow Rate Through Fan** option is enabled.

Tangential Source Term
enables a momentum source in the tangential direction, based on impeller theory.

Radial Source Term
enables a momentum source in the radial direction, based on impeller theory.

Axial Source Term
enables a momentum source in the axial direction, based on the settings in the **Axial Source Term Settings** group box.

Axial Source Term Settings
allows you to define the momentum source in the axial direction. This group box is only available when the **Axial Source Term** option is enabled.

Method
specifies whether a **constant pressure** or a **fan curve** (that is, a curve created from data points that plot pressure rise vs. volumetric flow rate) defines the axial momentum source.

Pressure Jump
defines the pressure jump that is applied across the 3D fan. This setting is only available when **constant pressure** is selected for the **Method**.

Read Fan Curve...
allows you to read a tab-delimited ASCII file that defines the relationship between pressure and flow rate for each 3D fan cell zone (see 3D Fan Curve File Format (p. 2869) for details). This button is only available when **fan curve** is selected for the **Method**.

Curve Fitting Method
specifies whether Fluent should apply a **polynomial** or **piecewise-linear** fitting method to construct a curve from the data points in the fan curve file. This drop-down list is only available when **fan curve** is selected for the **Method**.

Order of Polynomial
defines the order of the polynomial curve fitting method. This setting is only available when **polynomial** is selected for the **Curve Fitting Method**.

Initial Flow Rate
specifies your best estimate of the initial flow rate through the fan. This setting is only available when **fan curve** is selected for the **Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Test Angular Velocity
specifies the angular velocity of the fan used in the experiment that generated the fan curve data. This setting is only available when **fan curve** is selected for the **Method**.

Test Temperature
specifies the temperature of the fluid flowing through the fan during the experiment that generated the fan curve data. This setting is only available when **fan curve** is selected for the **Method**.

Reaction
lists the parameters for reactions in the porous zone.

Reaction Mechanism
allows you to specify a defined group, or mechanism, of available reactions. See Defining Zone-Based Reaction Mechanisms (p. 984) for details about defining reaction mechanisms.

Surface-to-Volume Ratio
specifies the surface area of the pore walls per unit volume ($\frac{A}{V}$), and can be thought of as a measure of catalyst loading. With this value, ANSYS Fluent can calculate the total surface area on which the reaction takes place in each cell by multiplying $\frac{A}{V}$ by the volume of the cell.

Source Terms
defines a source of heat, mass, momentum, turbulence, species, or other scalar quantity within the fluid zone.

Fixed Values
lists the fixed parameters of the fluid zone.

Local Coordinate System for Fixed Velocities
enables the specification of fixed cylindrical velocity components instead of Cartesian components. The local coordinate system is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction**.

This item is available only in 3D, and only when the **Fixed Values** option is on.

Multiphase
allows you to set parameters that are specific to the multiphase models.

Compressive Scheme Slope Limiter
ranges from 0 to 2. For example, a **Compressive Scheme Slope Limiter** of 0 corresponds to first order upwind behavior, a value of 1 corresponds to second order upwind, and a value of 2 applies the compressive scheme. The **Multiphase** tab is available only if **Zonal Discretization** is enabled in the Multiphase Model Dialog Box (p. 2171).

Numeric Beach Treatment
is available when **Open Channel Flow** and/or **Open Channel Wave BC** is enabled in the **Multiphase Model** dialog box (see Numerical Beach Treatment for Open Channels (p. 1432) for more detail).

Numerical Beach
when enabled expands the dialog box where you can specify the numerical beach parameters.

Beach Group ID
represents the cell zones sharing the damping length containing the same input parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Damping Type
allows you to choose between **One Dimensional** and **Two Dimensional** damping.

One Dimensional
is the damping treatment in the flow direction.

Two Dimensional
is the damping treatment in the flow and gravity direction.

Compute From Inlet Boundary
is set to **none** by default. If there are available open channel boundaries (velocity-inlet, pressure-inlet, and mass-flow-inlet), boundary names are added to the drop-down list. If you select a boundary from the list, the **Level Inputs**, **Damping Length Inputs in Flow Direction**, and **Damping Resistance** values will be updated in the interface. You have the option to overwrite the updated inputs with values that are more applicable to your simulation.

Level Inputs
is only available for the **Two Dimensional** damping type.

Free Surface Level
is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410).

Bottom Level
is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410), and is valid only for shallow waves. The bottom level is used for calculating the liquid height.

Flow Direction
is the X, Y, and Z (for 3D) components.

Damping Length Inputs in Flow Direction
are required to calculate the start and end points of the damping length in the flow direction.

Damping Length Specification
is only available if **Open Channel Wave BC** is enabled in the **Multiphase Model** dialog box. There are two options you can choose from **End Point and Wave Lengths** or **End and Start Points**.

End Point
is the end point of the damping zone.

Start Point
is the starting point in the flow direction.

Wave Length
is updated automatically if the boundary is selected from the **Compute From Inlet Boundary** drop-down list.

Number Of Wave Lengths
is set to 2 by default for the calculation of the damping length.

Relative Velocity Resistance Formulation
calculates the source term using relative velocities in the numerical beach zone when using moving/deforming meshes or moving reference frames.

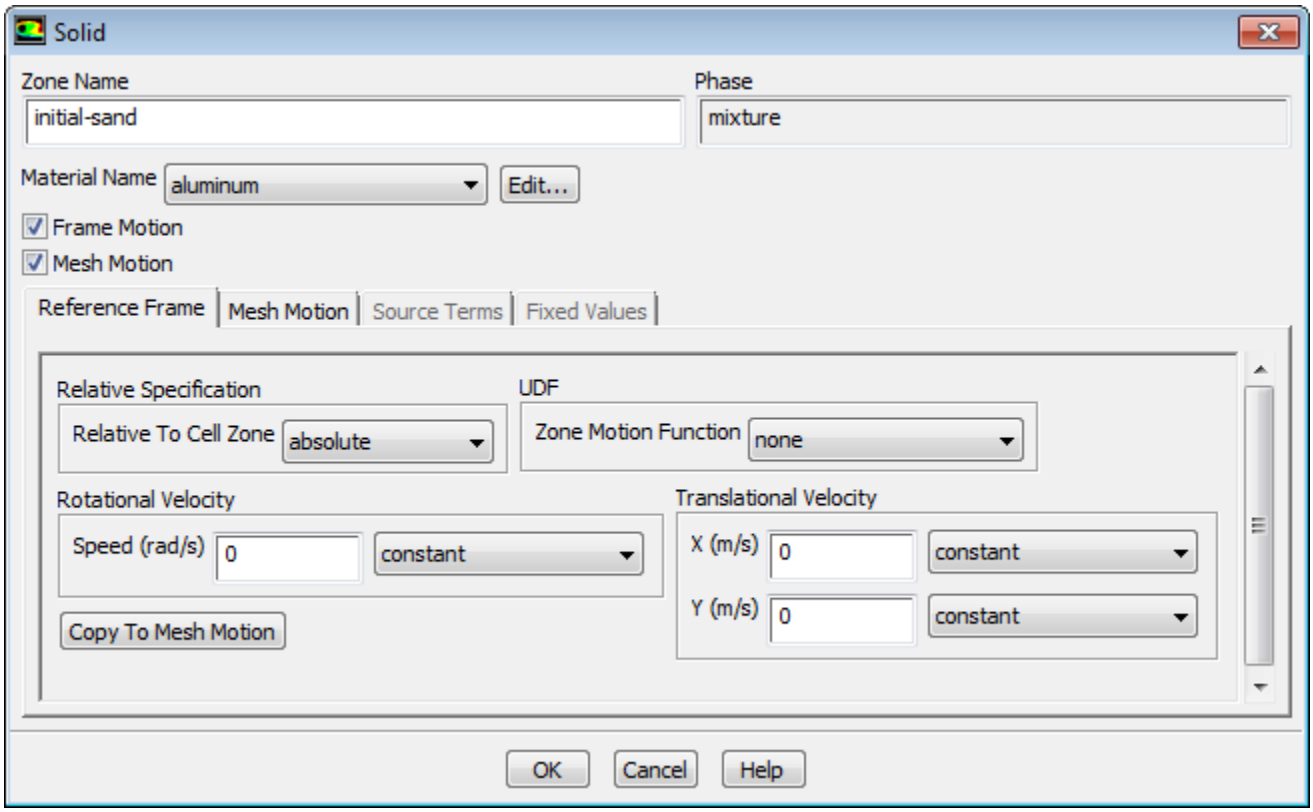
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Linear Damping Resistance
is the resistance per unit time.

Quadratic Damping Resistance
is the resistance per unit length.

37.7.2. Solid Dialog Box

The **Solid** dialog box sets the boundary conditions for a solid cell zone. It is opened from the Cell Zone Conditions Task Page (p. 2367). See Inputs for Solid Zones (p. 259) for details about the items below.



Controls

Zone Name
sets the name of the zone.

Material Name
selects the material type of the solid. Materials are defined with the Materials Task Page (p. 2300).

Frame Motion
enables the moving reference frame model for the cell zone. See Specifying the Rotation Axis (p. 255) and Defining Zone Motion (p. 256) for details.

Mesh Motion
enables the sliding mesh model for the cell zone. See Setting Up the Sliding Mesh Problem (p. 634) for details.

Source Terms
enables the specification of a volumetric source of energy. When you turn on this option, the **Source Term** tab will allow you to specify the value for the energy source. See Defining Mass, Momentum, Energy, and Other Sources (p. 297) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fixed Values
enables the fixing of the value of temperature in the solid zone, rather than computing it during the calculation. See Fixing the Values of Variables (p. 292) for details.

> **Important**
>
> You can fix the value of temperature only if you are using the pressure-based solver.

Participates In Radiation
specifies whether or not the solid zone participates in radiation. This option appears when you are using the DO model for radiation.

Reference Frame
lists the parameters that define motion for a moving reference frame.

Rotation-Axis Origin
specifies the origin for the axis of rotation of solid zone. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D and 2D non-axisymmetric models.

Rotation-Axis Direction
specifies the direction vector for the solid zone's axis of rotation. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D models.

Rotational Velocity
contains an input field for the rotational **Speed** of the zone.

Translational Velocity
contains inputs for the **X**, **Y**, and **Z** velocities of the zone.

Relative Specification
indicates whether the velocities are absolute velocities (**absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

UDF
allows you to hook the DEFINE_ZONE_MOTION user-defined function.

Copy to Mesh Motion
allows you to switch between the MRF and moving mesh models. The variables used for the origin, axis, and velocity components, as well as for the `DEFINE_ZONE_MOTION` user-defined function, will be copied from one model to the other.

Mesh Motion
lists the parameters that define motion for a moving reference frame.

Rotation-Axis Origin
specifies the origin for the axis of rotation of solid zone. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D and 2D non-axisymmetric models.

Rotation-Axis Direction
specifies the direction vector for the solid zone's axis of rotation. See Specifying the Rotation Axis (p. 260) for details. This item will appear only for 3D models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rotational Velocity
contains an input field for the rotational **Speed** of the zone.

Translational Velocity
contains inputs for the **X**, **Y**, and **Z** velocities of the zone.

Relative Specification
indicates whether the velocities are absolute velocities (**absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

UDF
allows you to hook the DEFINE_ZONE_MOTION user-defined function.

Copy to Frame Motion
allows you to switch between the MRF and moving mesh models. The variables used for the origin, axis, and velocity components, as well as for the `DEFINE_ZONE_MOTION` user-defined function, will be copied from one model to the other.

Source Term
lists the parameters for volumetric source of energy.

Energy
displays the total number of energy sources used.

User Scalar n
displays the total number of scalars used.

Fixed Values
lists the parameters that can be declared as fixed during the calculation.

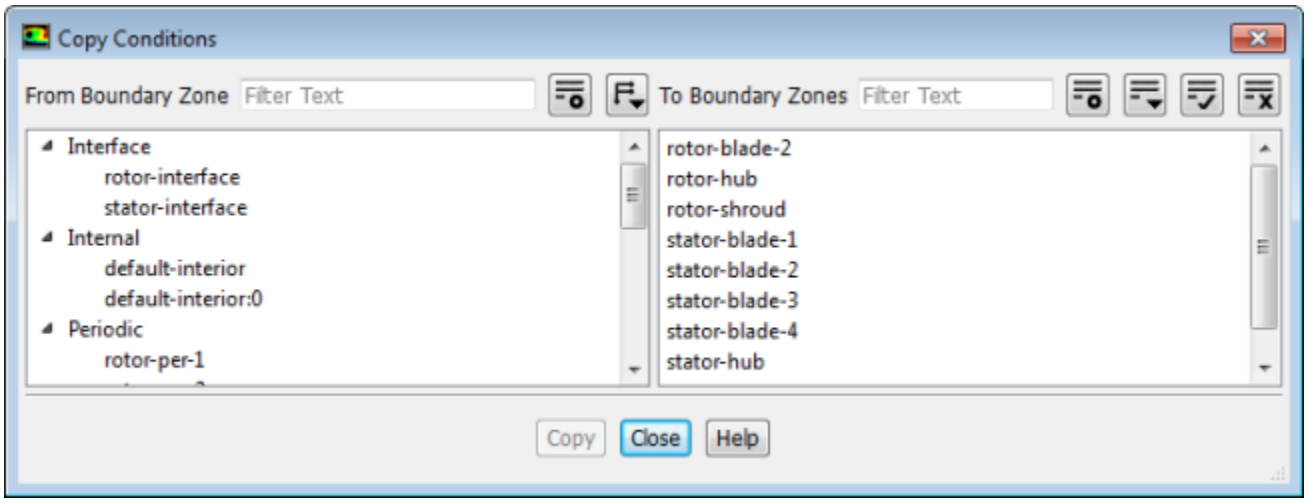
Temperature
specifies the fixed value for temperature.

User Scalar n
specifies the fixed value for user scalar.

37.7.3. Copy Conditions Dialog Box

The **Copy Conditions** dialog box allows you to copy cell zone and/or boundary conditions from one zone/boundary to other zones/boundaries of the same type. It is opened either from the Cell Zone Conditions Task Page (p. 2367) or from the Boundary Conditions Task Page (p. 2389). See Copying Cell Zone and Boundary Conditions (p. 242) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

From Zone
specifies the zone that has the conditions you want to copy.

To Zones
specifies the zone or zones to which you want to copy the conditions.

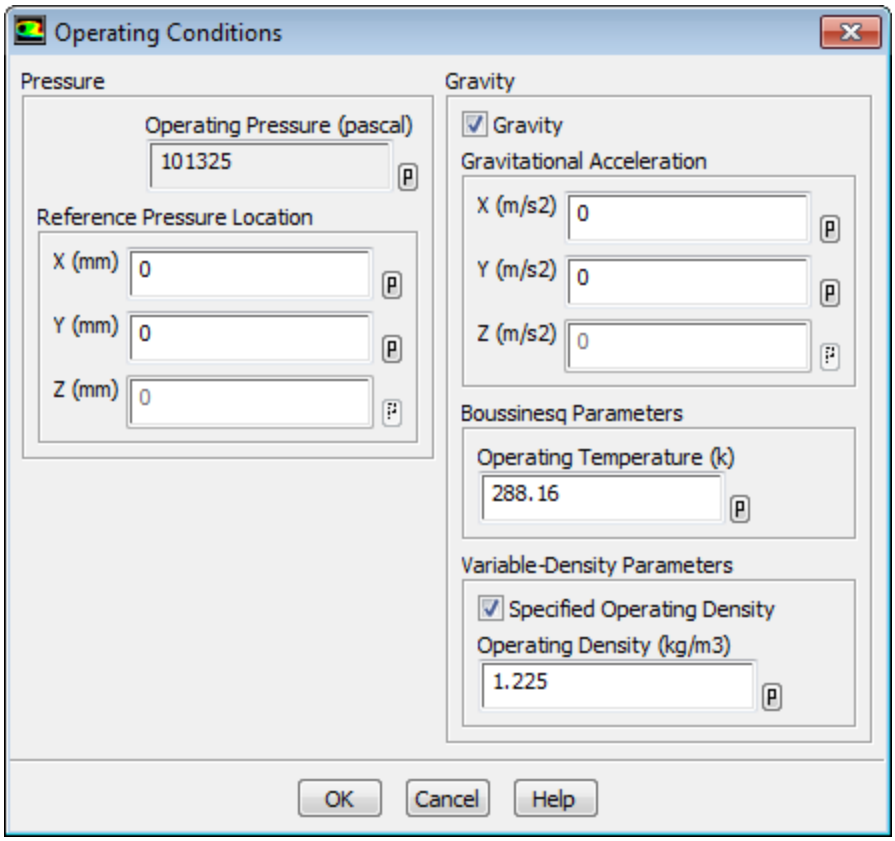
Phase
specifies the phase for which cell zone conditions or boundary conditions are being copied. This item appears if the VOF, mixture, or Eulerian multiphase model is being used. See Steps for Copying Cell Zone and Boundary Conditions (p. 1406) for details.

Copy
copies the cell zone conditions or boundary conditions, setting all of the conditions for the zones selected in the **To Zones** list to be the same as the conditions for the zone selected in the **From Zone** list.

37.7.4. Operating Conditions Dialog Box

The **Operating Conditions** dialog box allows you to set parameters related to operating conditions in your model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Pressure

contains items related to the modeling of pressure.

Floating Operating Pressure

specifies the use of a floating operating pressure. See Floating Operating Pressure (p. 597) for details. This option appears only for time-dependent compressible flows.

Operating Pressure

sets the operating pressure for the problem. For all flows, ANSYS Fluent uses gauge pressure internally. Any time an absolute pressure is needed, it is generated by adding the operating pressure to the relative pressure. See Operating Pressure (p. 530) for a detailed description of operating pressure and how to set it.

Reference Pressure Location

sets the location of the cell whose pressure value is used to adjust the gauge pressure field for incompressible flows that do not involve any pressure boundaries. See Reference Pressure Location (p. 531) for details.

Real Gas Phase

allows you to specify the operating conditions in the subcritical regime of your model. Note that if the operating conditions in your model are entirely in the supercritical regime, this setting will have no effect.

Note

This option appears only when a Cubic Equation of State Real Gas model is chosen.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Vapor
is the default option, and therefore assumes that the real gas phase is vapor.

Liquid
assumes that the real gas phase is liquid.

Gravity
contains inputs for gravitational acceleration, the Boussinesq model, and variable density.

Gravity
enables the specification of gravity.

Gravitational Acceleration
sets the x, y, and z components of the gravitational acceleration vector. (The z component is available only in 3D solvers.) See Natural Convection and Buoyancy-Driven Flows (p. 833) for details about buoyancy-driven flows. This option appears only when **Gravity** is enabled.

Boussinesq Parameters
contains inputs related to the Boussinesq model. This option appears only if **Energy** (in the Energy Dialog Box (p. 2175)) and **Gravity** are enabled. See The Boussinesq Model (p. 833) for more information on the Boussinesq model.

Operating Temperature
sets the operating temperature (T_0 in Equation 12.3 (p. 833)) for use with the Boussinesq approximation.

Variable-Density Parameters
contains inputs related to the modeling of variable density. This option appears only when **Gravity** is enabled.

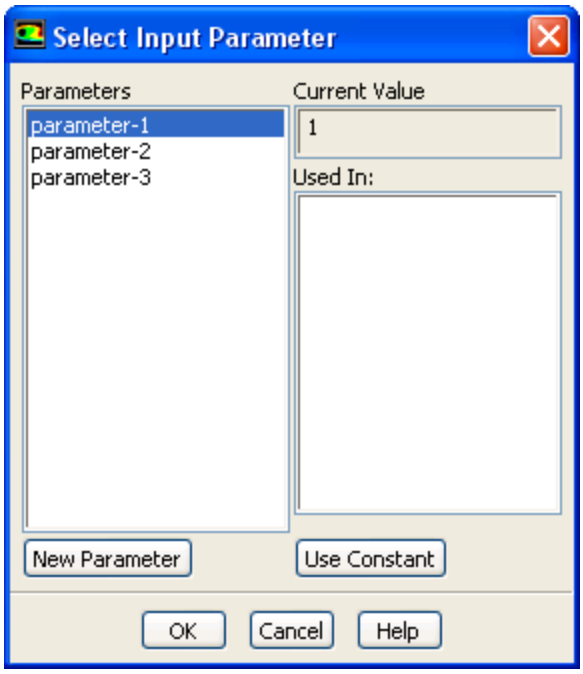
Specified Operating Density
enables the specification of operating density. See Operating Density (p. 836) for details.

Operating Density
sets the operating density (ρ_0 in Equation 12.4 (p. 836)). This parameter can be set only when **Specified Operating Density** is enabled.

37.7.5. Select Input Parameter Dialog Box

The **Select Input Parameter** dialog box allows you to choose from a listing of existing input parameters as well as to create and define new input parameters. For more information about parameters, see Defining and Viewing Parameters (p. 243) in the User's Guide, and see Working With Input and Output Parameters in Workbench in the ANSYS Fluent in Workbench User's Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Parameters
contains a list of existing compatible input parameters

Current Value
displays the value of the currently selected parameter.

Used In
lists any variables that are already associated with the currently selected parameter.

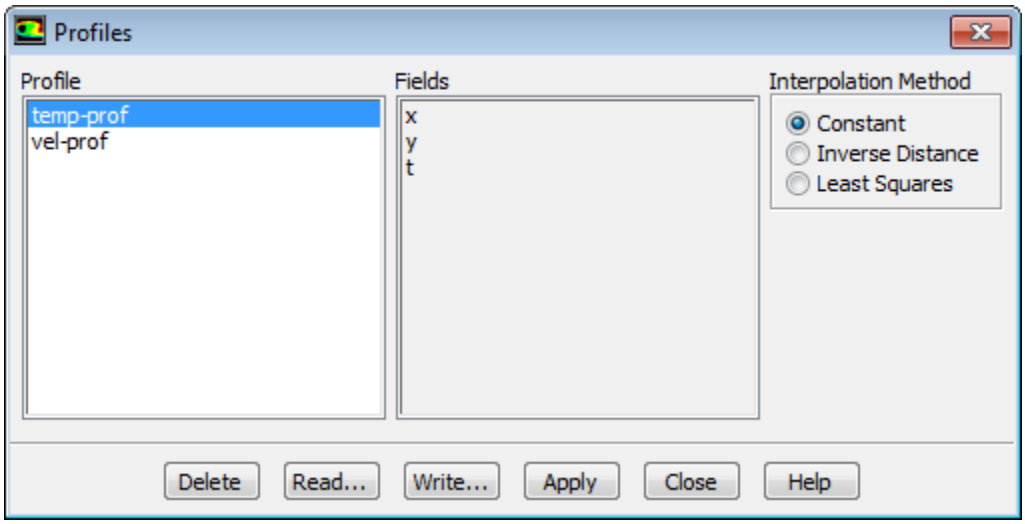
Use Constant
allows you to change the associated parameter to a constant (that is, real) value.

New Parameter
opens the Input Parameter Properties Dialog Box (p. 2631), in which you can assign names and values to an input parameter.

37.7.6. Profiles Dialog Box

The **Profiles** dialog box allows you to define new profiles by reading cell zone and boundary profile files. You can also examine the existing profile definitions and delete unused profiles. See Profiles (p. 435) for details about cell zone and boundary profiles.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Profile

contains a selectable list of available profiles. When a profile is selected its available fields are displayed under **Fields**.

Fields

displays the fields available in the selected profile. After the profile file has been read, these fields will also appear in any boundary condition dialog box (for example, the **Velocity Inlet** dialog box) that allows profile specification of a variable. To the right of (or below) the variable in the boundary conditions dialog box, there will be a drop-down list that contains a **constant** and the fields from available profile files. To use a particular profile field, just select it from the list.

Interpolation Method

allows you to select the interpolation method for the profile selected from the **Profile** list. This selection is only available for point profiles, and will only take effect when the **Apply** button is clicked. The choices include the following:

Constant

specifies that ANSYS Fluent should use zeroth-order interpolation to assign the point profile values to the nearest cell faces at the boundary. This is the default selection.

Inverse Distance

specifies that ANSYS Fluent should assign a value to each cell face at the boundary based on weighted contributions from the values in the point profile file. The weighting factor is inversely proportional to the distance between the profile point and the cell face center.

Least Squares

specifies that ANSYS Fluent should assign values to the cell faces at the boundary through a first-order interpolation method that tries to minimizes the sum of the squares of the offsets (residuals) between the profile data points and the cell face centers.

Delete

deletes the selected profile from memory.

Orient...

opens the Orient Profile Dialog Box (p. 2387), in which you can reorient and scale the profile. This item appears only in 3D.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

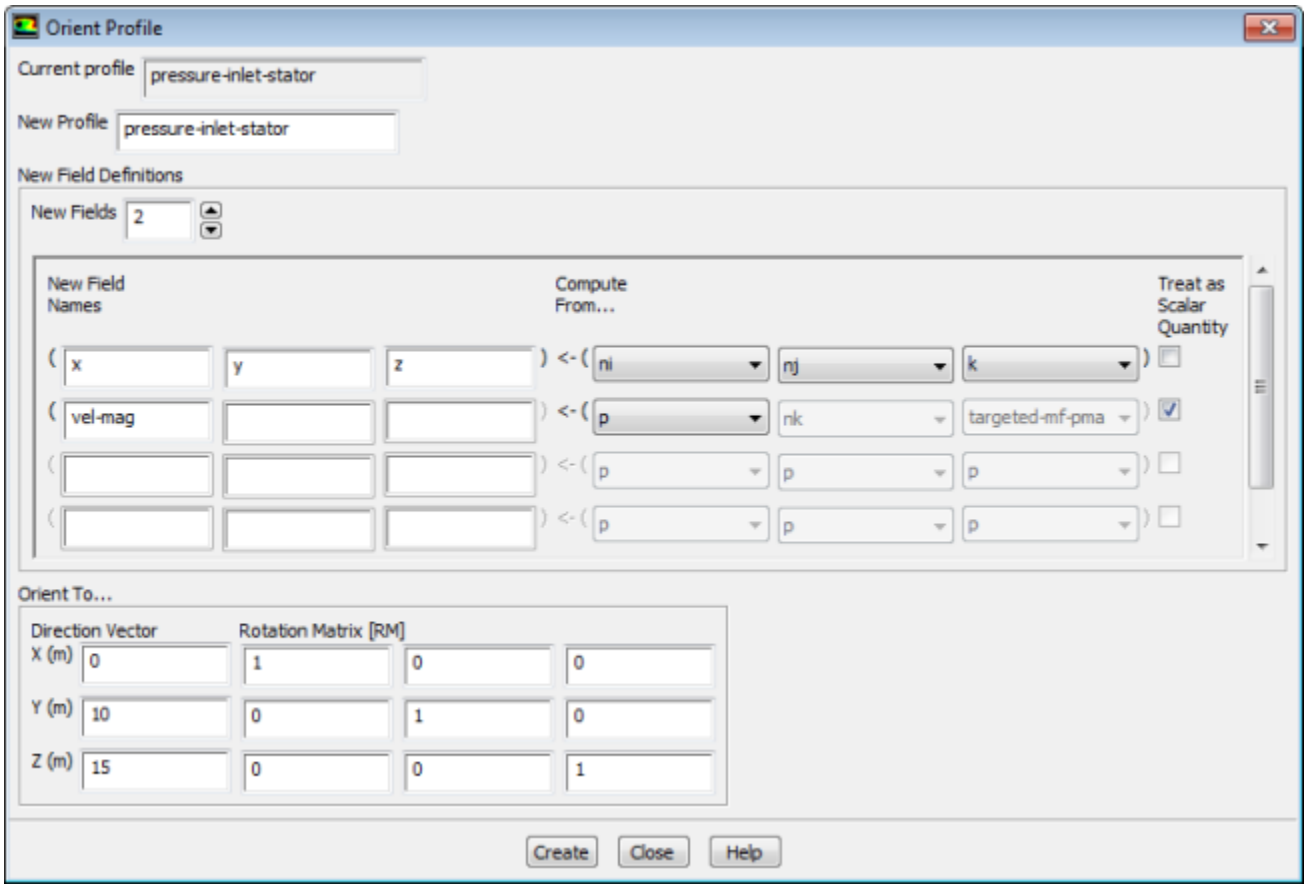
Read...
opens The Select File Dialog Box (p. 19) so that you can read a boundary profile file. If a profile in the file has the same name as an existing profile, the old profile will be overwritten.

Write...
opens the Write Profile Dialog Box (p. 2388), in which you can save profile data.

Apply
sets the selection made in the **Interpolation Method** list for point profiles in preparation for interpolation. The profile is not actually interpolated until a profile field is selected in a boundary condition dialog box (for example, the **Velocity Inlet** dialog box) and the solution is initialized.

37.7.7. Orient Profile Dialog Box

The **Orient Profile** dialog box allows you to reorient a profile so that you can apply it to a particular boundary. See Reorienting Profiles (p. 443) for details.



Controls

Current profile
shows the name of the currently selected profile in the Profiles Dialog Box (p. 2385). This is the profile on which the new profile will be based.

New Profile
sets the name of the new cell zone or boundary profile.

New Field Definitions
contains inputs and controls for the definition of the vector and scalar fields in the new profile.

New Fields
sets the number of data fields in the new profile.

New Field Names
contains inputs for the names of the data fields in the new profile. For a vector field, all 3 inputs in each row will be active; for a scalar field, only the first will be active.

Compute From...
contains drop-down lists with the names of the fields in the **Current profile**. In these lists, select the fields from which the **New Field Names** will be computed.

Treat as Scalar Quantity
indicates (if on) that the adjacent field is a scalar quantity. If this option is off, the field is a vector quantity.

Orient To...
contains inputs for the definition of the local coordinate system for the new profile. This coordinate system will determine the orientation of the profile.

Direction Vector
is the vector that translates a cell zone or boundary profile to the new position, and is defined between the centers of the profile fields.

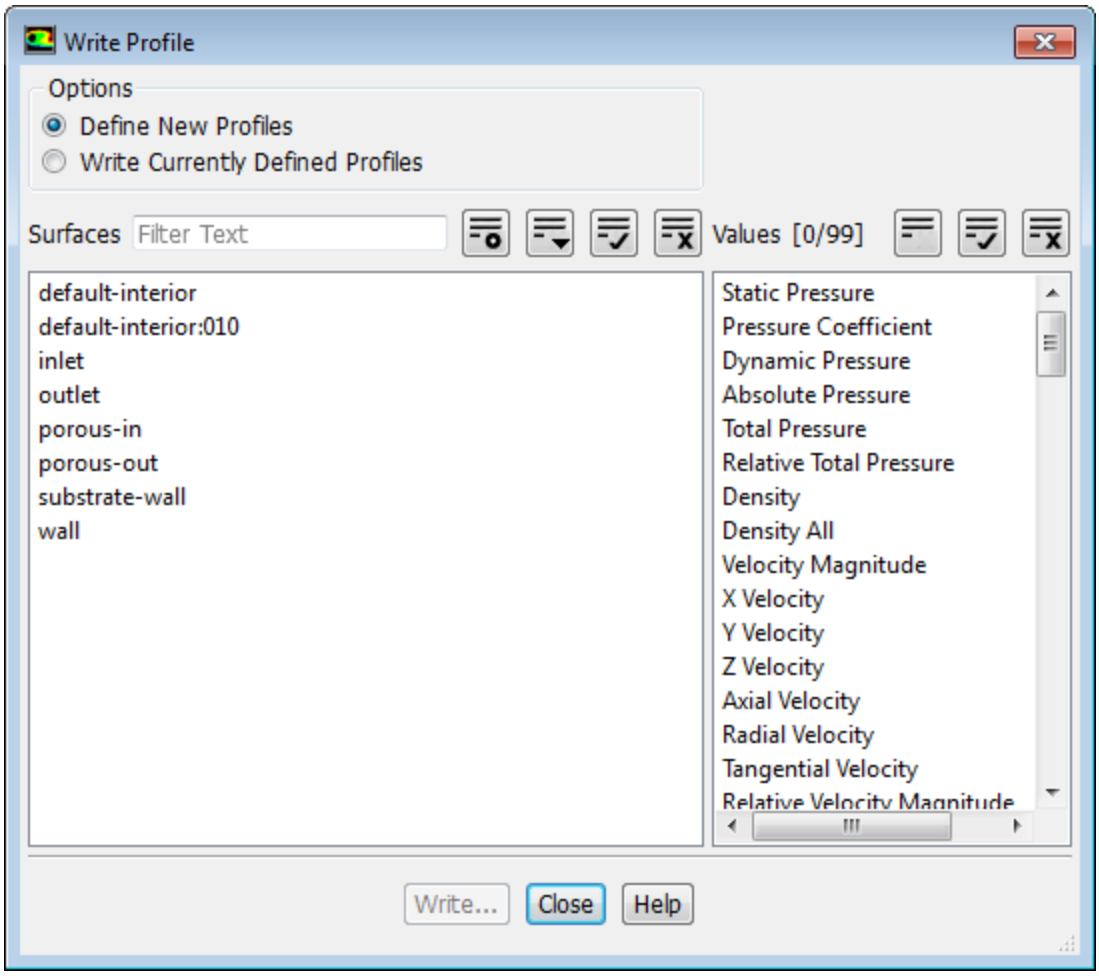
Rotation Matrix [RM
] specifies the rotational matrix RM, which is based on Euler angles (γ, β, and α) that define an orthogonal system $x'y'z'$ as the result of the three successive rotations from the original system xyz. See Reorienting Profiles (p. 443) for more information.

Create
creates a new profile using the information specified in the dialog box.

37.7.8. Write Profile Dialog Box

The **Write Profile** dialog box allows you to create a profile file from the conditions on a specified cell zone or boundary/surface. See Writing Profile Files (p. 54) for details on writing profile files.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains options for writing profiles.

Define New Profiles
enables the creation of a profile file from the conditions on a specified boundary or surface.

Write Currently Defined Profiles
enables the creation of a profile file containing all profiles that are currently defined.

Surfaces
contains a list from which you can select the surface(s) from which you want to extract data.

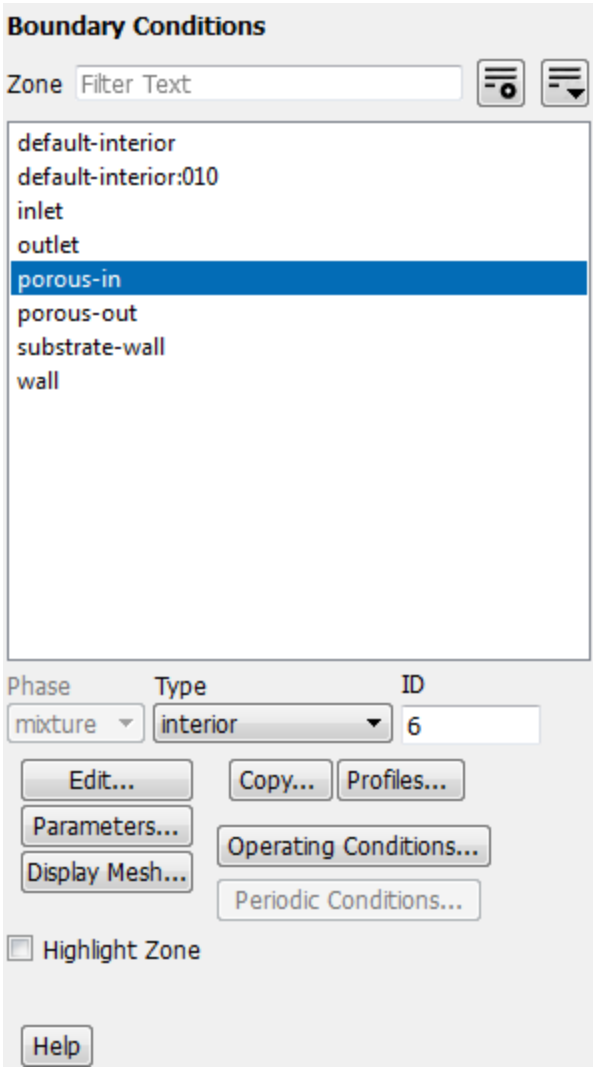
Values
contains a list from which you can select the variable(s) for which you want to create profiles.

Write...
opens The Select File Dialog Box (p. 19), in which you can specify a filename for the profile file.

37.8. Boundary Conditions Task Page

The **Boundary Conditions** task page allows you to set the type of a boundary and display other dialog boxes to set the boundary condition parameters for each boundary.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone

contains a selectable list of boundary zones from which you can select the zone of interest. You can check a zone type by using the mouse probe (see Controlling the Mouse Button Functions (p. 1800)) on the displayed physical mesh. This feature is particularly handy if you are setting up a problem for the first time, or if you have two or more boundary zones of the same type and you want to determine the zone IDs. To do this you must first display the mesh with the Mesh Display Dialog Box (p. 2163). Then click the boundary zone with the right (select) mouse button. ANSYS Fluent will print the zone ID and type of that boundary zone in the console window.

Phase

specifies the phase for which conditions at the selected boundary **Zone** are being set. This item appears if the VOF, mixture, or Eulerian multiphase model is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Type
contains a drop-down list of boundary condition types for the selected zone. The list contains all possible types to which the zone can be changed.

Important

Note that you cannot use this method to change zone types to or from the periodic type, since additional restrictions exist for this boundary type. Creating Conformal Periodic Zones (p. 214) explains how to create and uncouple periodic zones.

ID
displays the zone ID number of the selected zone. (This is for informational purposes only; you cannot edit this number.)

Edit...
opens the appropriate dialog box for setting the boundary conditions for that particular boundary type.

Copy...
opens the Copy Conditions Dialog Box (p. 2381), which allows you to copy boundary conditions from one zone to other zones of the same type. See Copying Cell Zone and Boundary Conditions (p. 242) for details.

Profiles...
opens the Profiles Dialog Box (p. 2385).

Parameters...
opens the Parameters Dialog Box (p. 2627).

Operating Conditions...
opens the Operating Conditions Dialog Box (p. 2382).

Display Mesh...
opens the Mesh Display Dialog Box (p. 2163).

Periodic Conditions...
opens the Periodic Conditions Dialog Box (p. 2468).

Highlight Zone
when enabled highlights the boundary zone (selected in the task page) in the graphics window.

For additional information, see the following sections:
37.8.1. Axis Dialog Box
37.8.2. Degassing Dialog Box
37.8.3. Exhaust Fan Dialog Box
37.8.4. Fan Dialog Box
37.8.5. Inlet Vent Dialog Box
37.8.6. Intake Fan Dialog Box

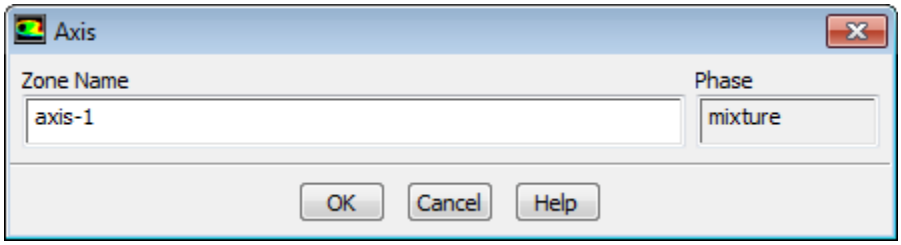
37.8.22. Wall Dialog Box
37.8.23. Periodic Conditions Dialog Box

37.8.1. Axis Dialog Box

The **Axis** dialog box can be used to modify the name of an axis zone; there are no conditions to be set. It is opened from the Boundary Conditions Task Page (p. 2389). See Axis Boundary Conditions (p. 389) for information about axis boundaries.



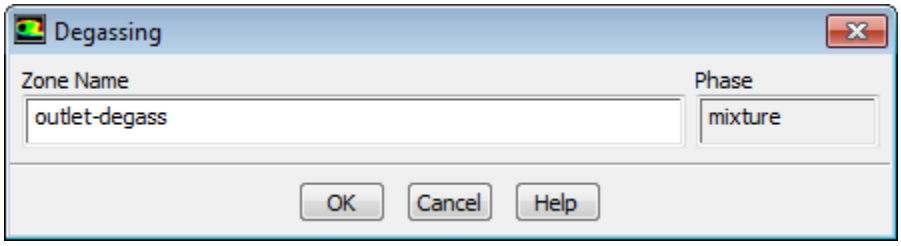
Controls

Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item appears if the VOF, mixture, or Eulerian multiphase model is being used.

37.8.2. Degassing Dialog Box

The **Degassing** dialog box can be used to modify the name of a degassing zone; there are no conditions to be set. It is opened from the Boundary Conditions Task Page (p. 2389). See Degassing Boundary Conditions (p. 357) for information about axis boundaries.



Controls

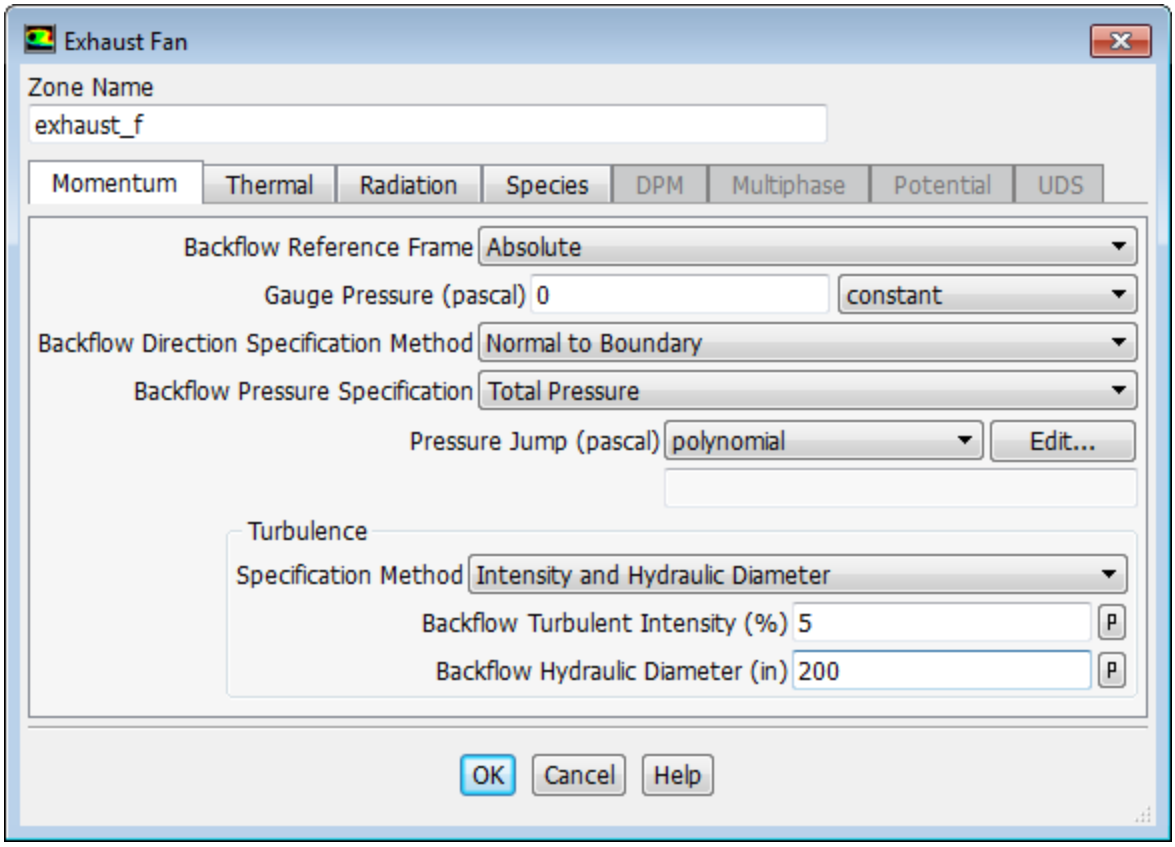
Zone Name
sets the name of the zone.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Phase
displays the name of the phase.

37.8.3. Exhaust Fan Dialog Box

The **Exhaust Fan** dialog box sets the boundary conditions for an exhaust fan zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Exhaust Fan Boundaries (p. 355) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Phase
displays the name of the phase. It appears only for multiphase flows.

Momentum
contains the momentum parameters.

Backflow Reference Frame
specify whether backflow temperature, pressure, and flow directions are in the **Absolute** or **Relative to the Adjacent Cell Zone** reference frame.

Gauge Pressure
sets the gauge pressure at the outlet boundary.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Backflow Direction Specification Method
sets the direction of the inflow stream should the flow reverse direction. You can choose **Direction Vector**, **Normal to Boundary**,or **From Neighboring Cell**.

Coordinate System
contains a drop-down list for selecting the coordinate system. You can choose **Cartesian**, **Cylindrical**, or **Local Cylindrical**. This option is available only when **Direction Vector** is selected from the **Backflow Direction Specification Method** drop-down list.

X-, Y-, Z-Component of Flow Direction
allows you to specify the velocity components in x, y, and z directions respectively. This option is available when **Cartesian** is selected for the **Coordinate System**.

Radial-, Tangential-, Axial-Component of Flow Direction
set the direction of the flow at the boundary. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Backflow Pressure Specification
specifies how the pressure is calculated under backflow conditions. If you select **Static Pressure**, the **Gauge Pressure** is directly imposed as the boundary face pressure; if you select **Total Pressure**, the **Gauge Pressure** will be combined with a dynamic contribution that is based on the velocity in the adjacent cell zone.

Pressure Jump
specifies the rise in pressure across the fan. See Specifying the Pressure Jump (p. 356) for details.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Turbulence
displays the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Backflow Turbulent Kinetic Energy, Backflow Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Backflow Turbulent Kinetic Energy, Backflow Specification Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Backflow Turbulent Intensity, Backflow Turbulent Viscosity Ratio

set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Hydraulic Diameter

set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Backflow Modified Turbulent Viscosity

sets the value of the backflow modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Backflow Turbulent Viscosity Ratio

sets the value of the backflow turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method

specifies which method will be used to determine the backflow Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulence Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

Backflow UU, VV, WW, UV, VW, UW Reynolds Stresses

specify the backflow Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Thermal

contains the thermal parameters. This parameter is available only when the energy equation is turned on.

Backflow Total Temperature

sets the total temperature of the inflow stream should the flow reverse direction.

Radiation

contains the boundary conditions for the radiation model at the exhaust fan.

External Black Body Temperature Method, Internal Emissivity

set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing

specifies whether or not the fan participates in solar ray tracing.

Solar Transmissivity Factor

specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the fan.

Participates in View Factor Calculation

specifies whether or not the fan participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.

Backflow Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters. This tab is available only if you have defined at least one injection.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution (see Particle Reflection at Wall in the *Fluent Theory Guide*).

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Backflow Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction Specification Method
sets the method used to specify the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Backflow Volume Fraction
specifies the volume fraction of the secondary phase as a constant, profile, of UDF function.

From Neighboring Cell
calculates the volume fraction from the neighboring cells.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

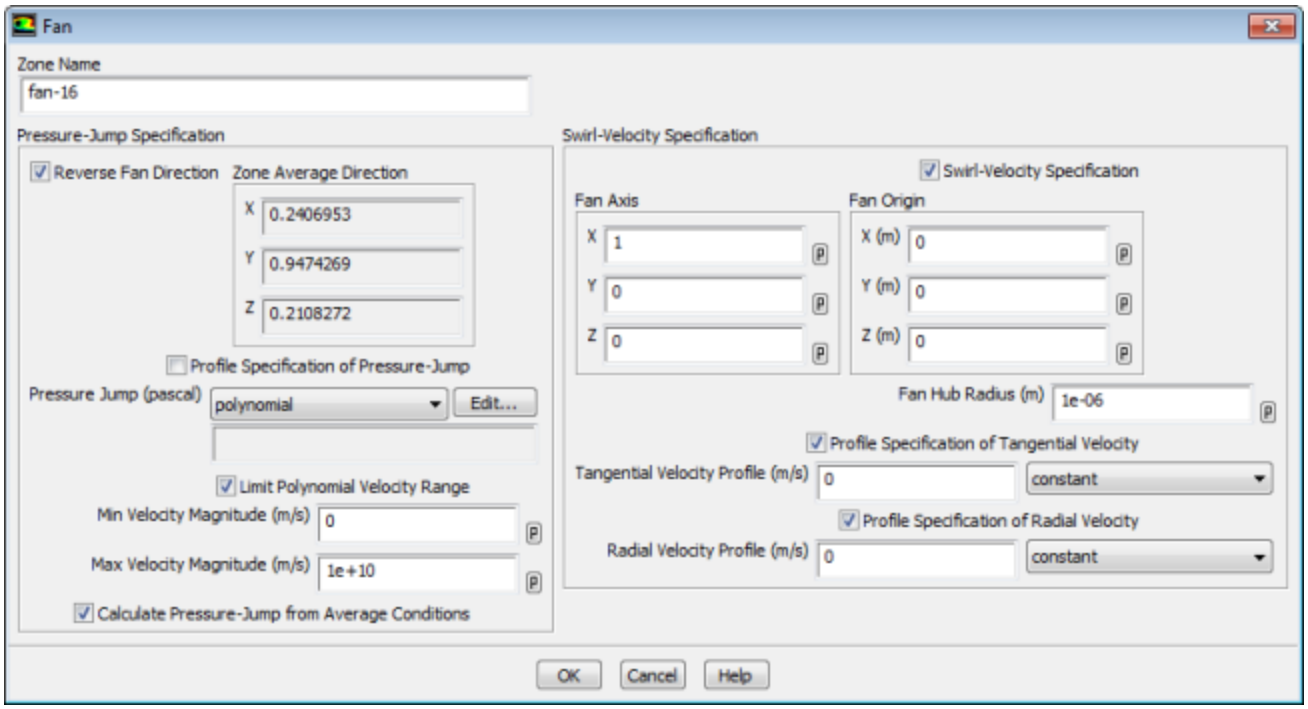
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

37.8.4. Fan Dialog Box

The **Fan** dialog box sets the boundary conditions for a fan zone. It is opened from the Boundary Conditions Task Page (p. 2389). See User Inputs for Fans (p. 391) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name
sets the name of the zone.

Pressure-Jump Specification
contains inputs that define the pressure jump across the fan.

Reverse Fan Direction
sets the fan flow direction relative to the zone direction. If **Zone Average Direction** is pointing in the direction you want the fan to blow, do *not* select **Reverse Flow**; if it is pointing in the opposite direction, select **Reverse Flow**.

Zone Average Direction
displays the (face-averaged) direction vector for the zone as an aid in determining whether or not you want to select **Reverse Flow**.

Profile Specification of Pressure-Jump
enables the use of a boundary profile or user-defined function for the pressure jump specification. See Profiles (p. 435) or the Fluent Customization Manual for details. When this option is enabled, **Pressure Jump Profile** will appear in the dialog box and the next four items below it will not.

Pressure Jump Profile
contains a drop-down list from which you can select a boundary profile or a user-defined function for the pressure jump definition. This item will appear if you enable **Profile Specification of Pressure-Jump**.

Pressure-Jump
specifies the pressure-jump as a constant value or as a polynomial, piecewise-linear, or piecewise-polynomial function of velocity. See Defining the Pressure Jump (p. 392) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Limit Polynomial Velocity Range
limits the minimum and maximum velocity magnitudes used to calculate the pressure jump when it is defined as a function of velocity.

Min Velocity Magnitude, Max Velocity Magnitude
specify the minimum and maximum values to which the velocity magnitude is limited (when the **Limit Polynomial Velocity Range** option is enabled).

Calculate Pressure-Jump from Average Conditions
enables the option to use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

interior
allows the particles to pass through the boundary.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Swirl-Velocity Specification
contains inputs for the specification of fan swirl velocity. This section of the dialog box appears only for 3D models.

Swirl-Velocity Specification
enables the specification of a swirl velocity for the fan.

Fan Axis
sets the direction vector for the fan's axis of rotation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fan Origin
sets the origin in the global coordinate system through which the fan rotation axis passes.

Fan Hub Radius
set the radius of the hub. The default is 1e-6 to avoid division by zero in the polynomial.

Profile Specification of Tangential Velocity
enables the use of a boundary profile or user-defined function for the tangential velocity specification. See Profiles (p. 435) or the Fluent Customization Manual for details. When this option is enabled, **Tangential Velocity Profile** will appear in the dialog box and **Tangential-Velocity Polynomial Coefficients** will not.

Tangential Velocity Profile
contains a drop-down list from which you can select a boundary profile or a user-defined function for the definition of the tangential velocity. This item will appear if you enable **Profile Specification of Tangential Velocity**.

Tangential-Velocity Polynomial Coefficients
sets the coefficients for the tangential velocity polynomial. Separate the coefficients by spaces.

Profile Specification of Radial Velocity
enables the use of a boundary profile or user-defined function for the radial velocity specification. See Profiles (p. 435) or the Fluent Customization Manual for details. When this option is enabled, **Radial Velocity Profile** will appear in the dialog box and **Radial-Velocity Polynomial Coefficients** will not.

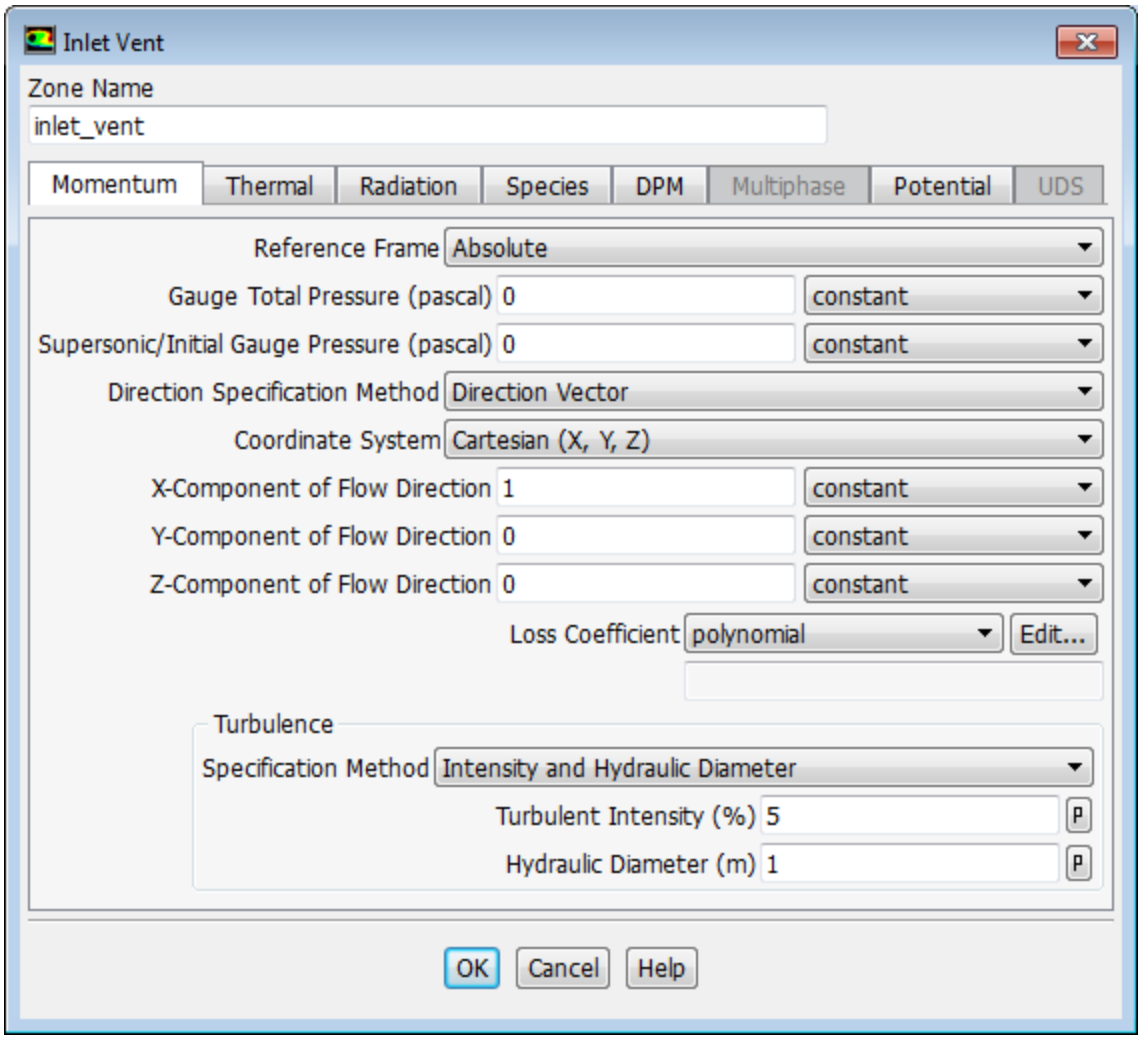
Radial Velocity Profile
contains a drop-down list from which you can select a boundary profile or a user-defined function for the definition of the radial velocity. This item will appear if you enable **Profile Specification of Radial Velocity**.

Radial-Velocity Polynomial Coefficients
sets the coefficients for the radial velocity polynomial. Separate the coefficients by spaces.

37.8.5. Inlet Vent Dialog Box

The **Inlet Vent** dialog box sets the boundary conditions for an inlet vent zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Inlet Vent Boundaries (p. 334) for details about defining the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name

sets the name of the zone.

Momentum

contains the momentum parameters.

Reference Frame

specifies the reference frame for the inlet vent. If the cell zone adjacent to the inlet vent is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list.

Gauge Total Pressure

sets the gauge total (or stagnation) pressure of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total pressure.

Supersonic/Initial Gauge Pressure

sets the static pressure on the boundary when the flow becomes (locally) supersonic. It is also used to compute initial values for pressure, temperature, and velocity if the inlet vent boundary condition is selected for computing initial values (see Initializing the Entire Flow Field Using Standard Initialization (p. 1591)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Direction Specification Method
specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** no inputs are required. See Defining the Flow Direction (p. 311) for information on specifying flow direction.

Coordinate System
specifies whether **Cartesian**, **Cylindrical**, **Local Cylindrical**, **Local Cylindrical Swirl** vector components will be specified. This item will appear only for 3D cases in which you have selected **Direction Vector** as the **Direction Specification Method**.

X,Y,Z-Component of Flow Direction
set the direction of the flow at the inlet boundary. These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial, Tangential, Axial Component of Flow Direction
set the direction of the flow at the inlet boundary. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Loss-Coefficient
sets the non-dimensional loss coefficient used to compute the pressure drop. See Specifying the Loss Coefficient (p. 335) for details.

Turbulence
lists the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Turbulence Intensity, Turbulence Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Turbulence Intensity, Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Turbulence Intensity, Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity
sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio
sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulence Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Thermal
contains the thermal parameters.

Total Temperature
sets the total temperature of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total temperature.

Radiation
contains the radiation parameters.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the inlet vent participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the inlet vent.

Participates in View Factor Calculation
specifies whether or not the inlet vent participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. (These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.)

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction
specifies the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Open Channel
is available when the VOF model with open channel flow is enabled.

Secondary Phase for Inlet
is where the specified parameters are valid only for one secondary phase. In case of a three-phase flow, select the corresponding secondary phase from this list. This appears when **Open Channel** is enabled.

Flow Specification Method
allows you to select the type of flow. You can choose **Free Surface Level and Velocity**, **Total Height and Velocity**, or **Free Surface Level and Total Height**. This appears when **Open Channel** is enabled.

Free Surface Level
can be determined using the absolute value of height from the free surface to the origin in the direction of gravity, or by applying the correct sign based on whether the free surface level is above or below the origin.

Total Height
is used as an option for describing the flow. It is given by Equation 24.4 (p. 1414).

Bottom Level
is valid only for shallow waves. The bottom level is used for calculating the liquid height.

Velocity Magnitude
sets the magnitude of the velocity vector at the inflow boundary.

Level-Set Function Flux
appears if the **Level Set** option is enabled for the VOF model.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

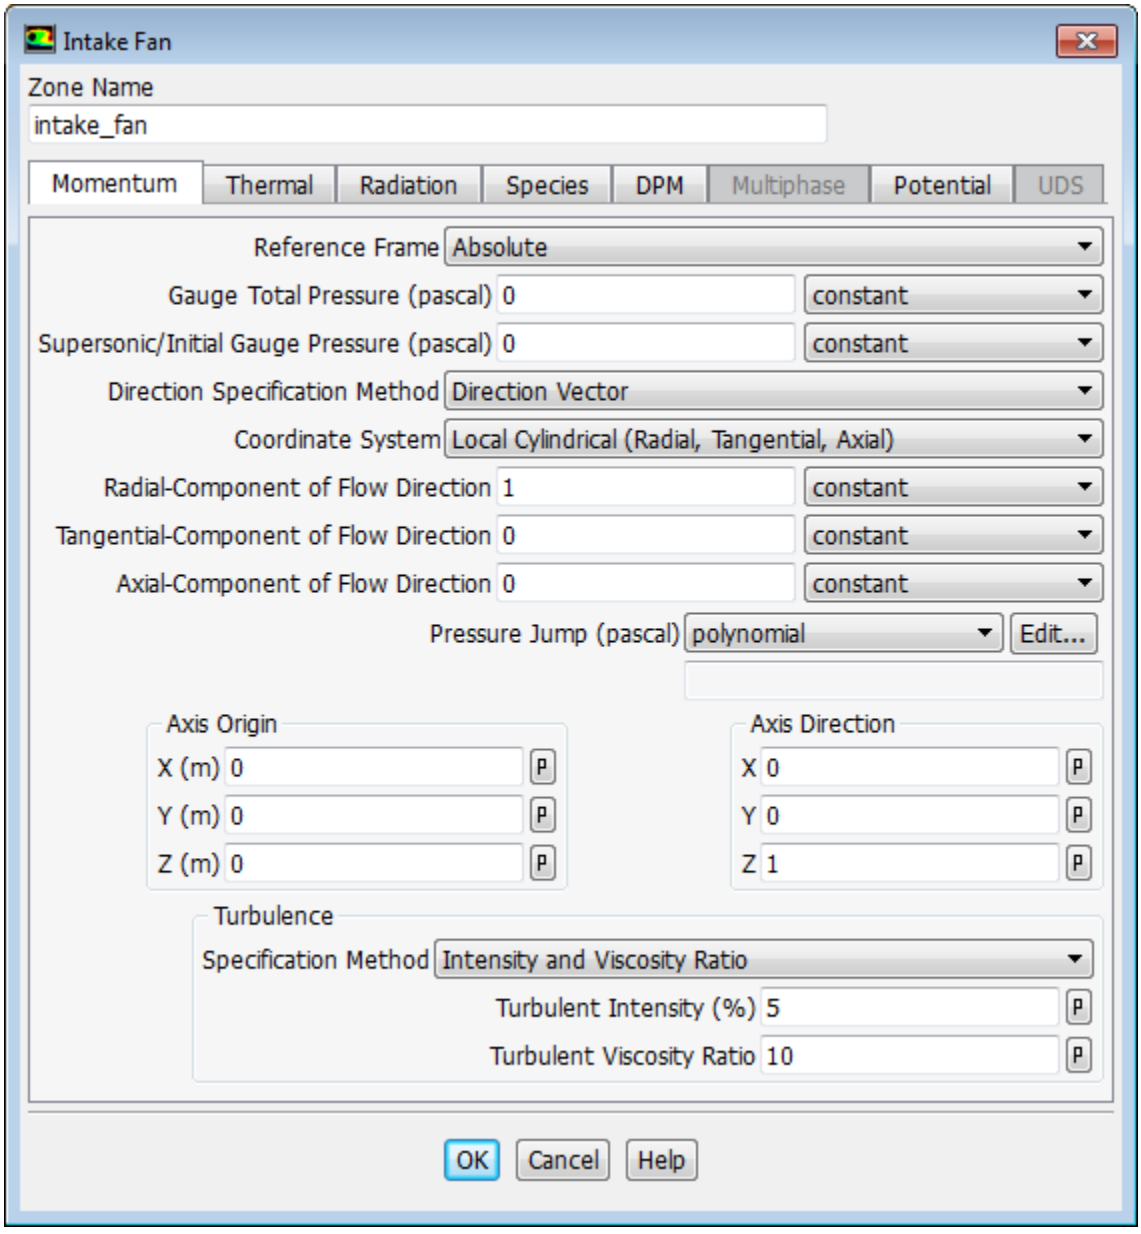
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

37.8.6. Intake Fan Dialog Box

The **Intake Fan** dialog box sets the boundary conditions for an intake fan zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Intake Fan Boundaries (p. 336) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Momentum
contains the momentum parameters.

Reference Frame
specifies the reference frame for the intake fan. If the cell zone adjacent to the intake fan is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list.

Gauge Total Pressure
sets the gauge total (or stagnation) pressure of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total pressure.

Supersonic/Initial Gauge Pressure
sets the static pressure on the boundary when the flow becomes (locally) supersonic. It is also used to compute initial values for pressure, temperature, and velocity if the intake fan boundary condition is selected for computing initial values (see Initializing the Entire Flow Field Using Standard Initialization (p. 1591)).

Direction Specification Method
specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** no inputs are required. See Defining the Flow Direction (p. 311) for information on specifying flow direction.

Coordinate System
specifies whether **Cartesian**, **Cylindrical**, **Local Cylindrical**,or **Local Cylindrical Swirl** vector components will be defined. This item will appear only for 3D cases in which you have selected **Direction Vector** as the **Direction Specification Method**.

X-, Y-, Z-Component of Flow Direction
set the direction of the flow at the inlet boundary. For compressible flow, if the inflow becomes supersonic, the velocity is not reoriented. These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial-, Tangential-, Axial-Component of Flow Direction
set the direction of the flow at the inlet boundary. For compressible flow, if the inflow becomes supersonic, the velocity is not reoriented. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Pressure Jump
specifies the rise in pressure across the fan. See Specifying the Pressure Jump (p. 338) for details.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Turbulence
consists of the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scale, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Turbulent Intensity, Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Turbulent Intensity, Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity, Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity
sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio
sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Thermal
contains the thermal parameters.

Total Temperature
sets the total temperature of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total temperature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Radiation
contains the radiation parameters.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the intake fan participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the intake fan.

Participates in View Factor Calculation
specifies whether or not the intake fan participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. (These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.)

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction
specifies the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

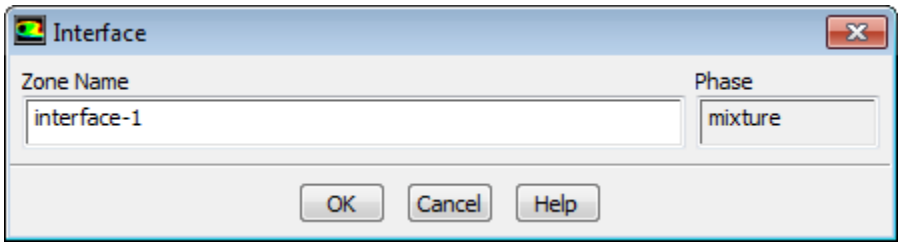
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Scalar n
specifies the value of the scalar.

37.8.7. Interface Dialog Box

The **Interface** dialog box can be used to modify the name of an interface zone; there are no conditions to be set. It is opened from the Boundary Conditions Task Page (p. 2389). Interface zones are used for multiple reference frame and sliding mesh calculations, and for non-conformal meshes. See The Multiple Reference Frame Model (p. 613), Setting Up the Sliding Mesh Problem (p. 634), and Non-Conformal Meshes (p. 150) for details.



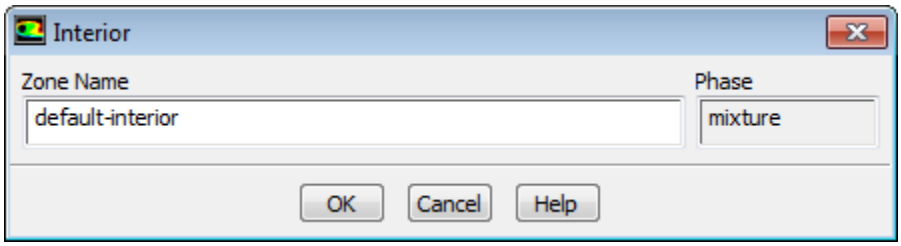
Controls

Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item appears only for multiphase flows.

37.8.8. Interior Dialog Box

The **Interior** dialog box can be used to modify the name of an interior zone; there are no conditions to be set. It is opened from the Boundary Conditions Task Page (p. 2389).



Controls

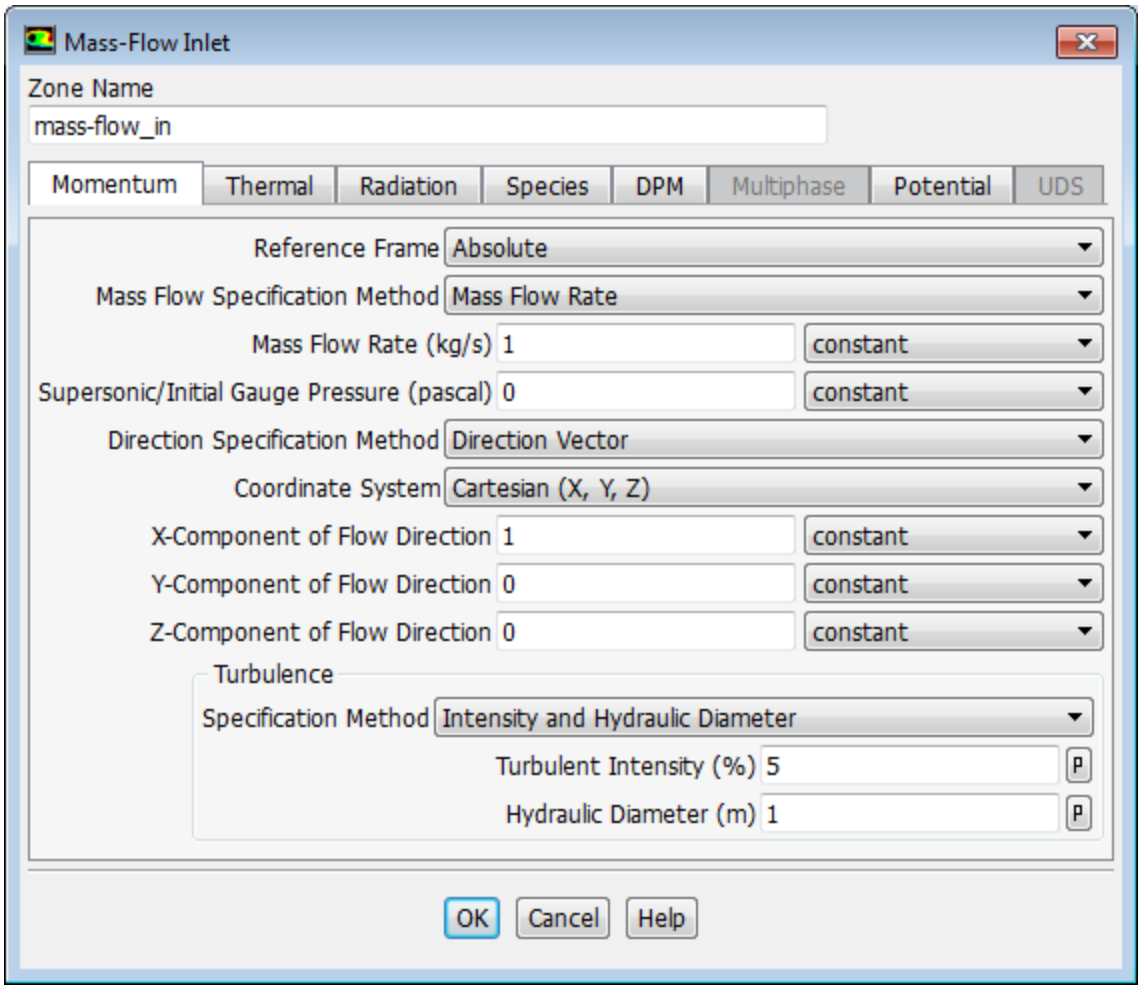
Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item appears only for multiphase flows.

37.8.9. Mass-Flow Inlet Dialog Box

The **Mass-Flow Inlet** dialog box sets the boundary conditions for a mass-flow inlet zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Mass-Flow Inlet Boundaries (p. 323) for details about defining the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name
sets the name of the zone.

Momentum
displays the momentum boundary conditions.

Reference Frame
specifies the reference frame for the mass flow. If the cell zone adjacent to the mass-flow inlet is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list.

Mass Flow Specification Method
specifies whether you are defining **Mass Flow Rate**, **Mass Flux**, or **Mass Flux with Average Mass Flux**.

Mass Flow Rate
sets the prescribed mass flow rate for the zone. This flow rate is converted internally to a prescribed uniform mass flux over the zone by dividing the flow rate by the flow direction area projection of the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

zone. This item will appear if you selected **Mass Flow Rate** in the **Mass Flow Specification Method** list.

Important

Note that for axisymmetric problems, this mass flow rate is the flow rate through the entire (2π-radian) domain, not through a 1-radian slice.

Mass Flux

sets the prescribed mass flux for the zone. This item will appear if you selected **Mass Flux** or **Mass Flux with Average Mass Flux** in the **Mass Flow Specification Method** list.

Important

Note that for axisymmetric problems, this mass flux is the flux through a 1-radian slice of the domain.

Average Mass Flux

sets the average mass flux through the zone. See More About Mass Flux and Average Mass Flux (p. 325) for details. This item will appear if you selected **Mass Flux with Average Mass Flux** in the **Mass Flow Specification Method** list.

Important

Note that for axisymmetric problems, this mass flux is the flux through a 1-radian slice of the domain.

Supersonic/Initialization Gauge Pressure

sets the static pressure that will be used to initialize the flow field if the mass flow inlet boundary condition is selected for initializing flow properties (see Initializing the Entire Flow Field Using Standard Initialization (p. 1591)).

Direction Specification Method

specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** no inputs are required. See Defining the Flow Direction (p. 311) for information on specifying flow direction.

Coordinate System

specifies whether **Cartesian**, **Cylindrical**, **Local Cylindrical**,or **Local Cylindrical Swirl** vector components will be defined. This item will appear only for 3D cases in which you have selected **Direction Vector** as the **Direction Specification Method**.

X-, Y-, Z-Component of Flow Direction

set the velocity-direction vector of the inflow stream. This vector does not need to be normalized (for example, you can specify the vector (1 1 1) rather than (0.577 0.577 0.577)). These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial-, Tangential-, Axial-Component of Flow Direction

set the velocity-direction vector of the inflow stream. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axial-, Radial-Component of Flow Direction, Tangential-Velocity
appear for a 3D **Local Cylindrical Swirl** coordinate system.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical (swirl) coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical (swirl) coordinate system.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Turbulent Intensity, Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Turbulent Intensity, Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity, Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity
sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio
sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Acoustic Wave Model
contains settings for treatment of acoustic pressure waves at the boundary.

Off
disables special treatment of acoustic pressure waves at the boundary.

Non Reflecting
enables the general non-reflecting boundary condition treatment described in General Non-Reflecting Boundary Conditions (p. 416).

Impedance
enables the impedance boundary condition treatment described in Impedance Boundary Conditions (p. 422).

Transparent Flow Forcing
enables the transparent flow forcing boundary condition described in Transparent Flow Forcing Boundary Conditions (p. 425).

Impedance Parameters
contains the parameters for the impedance boundary condition treatment. For details refer to Using the Impedance Boundary Condition (p. 424).

Transparent Flow Forcing Parameters
contains the parameters for the transparent flow forcing boundary condition treatment. For details refer to Using the Transparent Flow Forcing Boundary Condition (p. 426).

Thermal
contains the thermal parameters.

Total Temperature
sets the total temperature of the inflow stream.

Radiation
contains the radiation parameters.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the mass-flow inlet participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the mass-flow inlet.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Participates in View Factor Calculation
specifies whether or not the mass-flow inlet participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

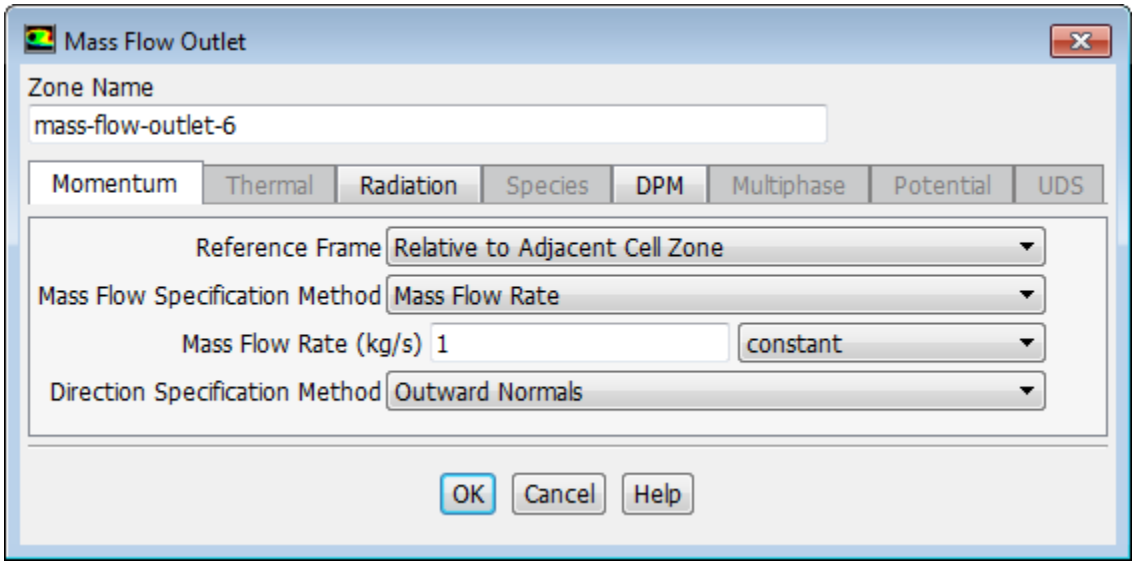
User Scalar n
specifies whether the scalar is a specified flux or a specified value.

User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

37.8.10. Mass Flow Outlet Dialog Box

The **Mass Flow Outlet** dialog box sets the boundary conditions for a mass-flow outlet zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Mass-Flow Outlet Boundaries (p. 330) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Momentum
displays the momentum boundary conditions.

Reference Frame
specifies the reference frame for the mass flow when the cell zone adjacent to the mass-flow outlet is moving. The only available option is **Relative to Adjacent Cell Zone**, so you must define the mass flow relative to the adjacent cell zone.

Mass Flow Specification Method
specifies whether you are defining **Mass Flow Rate**, **Mass Flux**, or **Mass Flux with Average Mass Flux**.

Mass Flow Rate
sets the prescribed mass flow rate for the zone. This flow rate is converted internally to a prescribed uniform mass flux over the zone by dividing the flow rate by the flow direction area projection of the zone. This item will appear if you selected **Mass Flow Rate** from the **Mass Flow Specification Method** drop-down list.

Important

Note that for axisymmetric problems, this mass flow rate is the flow rate through the entire (2π-radian) domain, not through a 1-radian slice.

Mass Flux
sets the prescribed mass flux for the zone. This item will appear if you selected **Mass Flux** or **Mass Flux with Average Mass Flux** from the **Mass Flow Specification Method** drop-down list.

Important

Note that for axisymmetric problems, this mass flux is the flux through a 1-radian slice of the domain.

Average Mass Flux
sets the average mass flux through the zone. See More About Mass Flux and Average Mass Flux (p. 332) for details. This item will appear if you selected **Mass Flux with Average Mass Flux** from the **Mass Flow Specification Method** drop-down list.

Important

Note that for axisymmetric problems, this mass flux is the flux through a 1-radian slice of the domain.

Direction Specification Method
specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components; if you choose **Outward Normals**, the flow direction will be out of the domain normal to boundary (and no further inputs are required). See Defining the Flow Direction (p. 332) for information on specifying flow direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Coordinate System
specifies whether **Cartesian**, **Cylindrical**, **Local Cylindrical**,or **Local Cylindrical Swirl** vector components will be defined. This item will appear only for 3D cases in which you have selected **Direction Vector** as the **Direction Specification Method**.

X-, Y-, Z-Component of Flow Direction
set the velocity-direction vector of the outflow stream. This vector does not need to be normalized (for example, you can specify the vector (1 1 1) rather than (0.577 0.577 0.577)). These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial-, Tangential-, Axial-Component of Flow Direction
set the velocity-direction vector of the outflow stream. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Axial-, Radial-Component of Flow Direction, Tangential-Velocity
appear for a 3D **Local Cylindrical Swirl** coordinate system.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical (swirl) coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical (swirl) coordinate system.

Radiation
contains the radiation parameters.

External Black Body Temperature Method, Black Body Temperature, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the mass-flow outlet participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the mass-flow outlet.

Participates in View Factor Calculation
specifies whether or not the mass-flow outlet participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

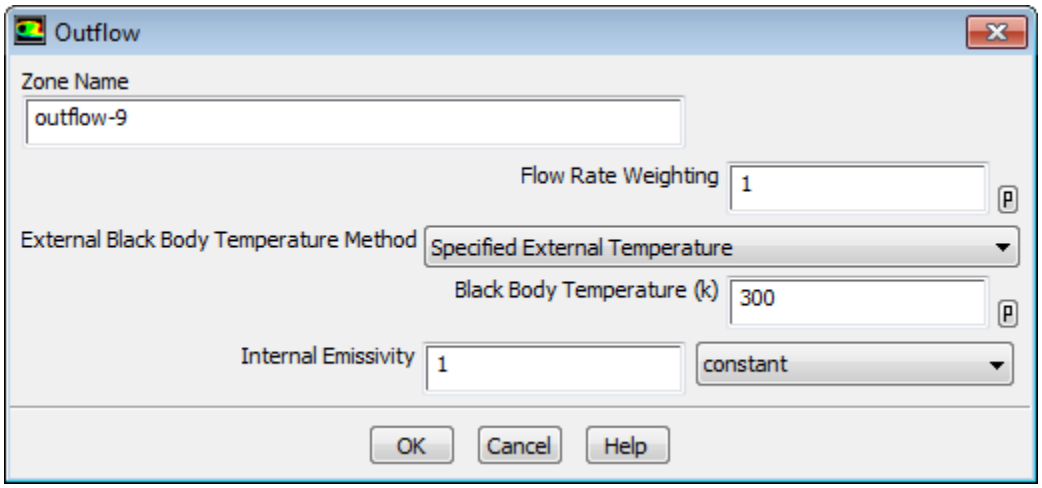
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

37.8.11. Outflow Dialog Box

The **Outflow** dialog box sets the boundary conditions for an outflow zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Using Outflow Boundaries (p. 351) for details about using outflow boundaries.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name
sets the name of the zone.

Flow Rate Weighting
specifies the portion of the outflow that is going through the boundary. See Mass Flow Split Boundary Conditions (p. 352) for details.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Participates in Solar Ray Tracing
specifies whether or not outflow participate in solar ray tracing.

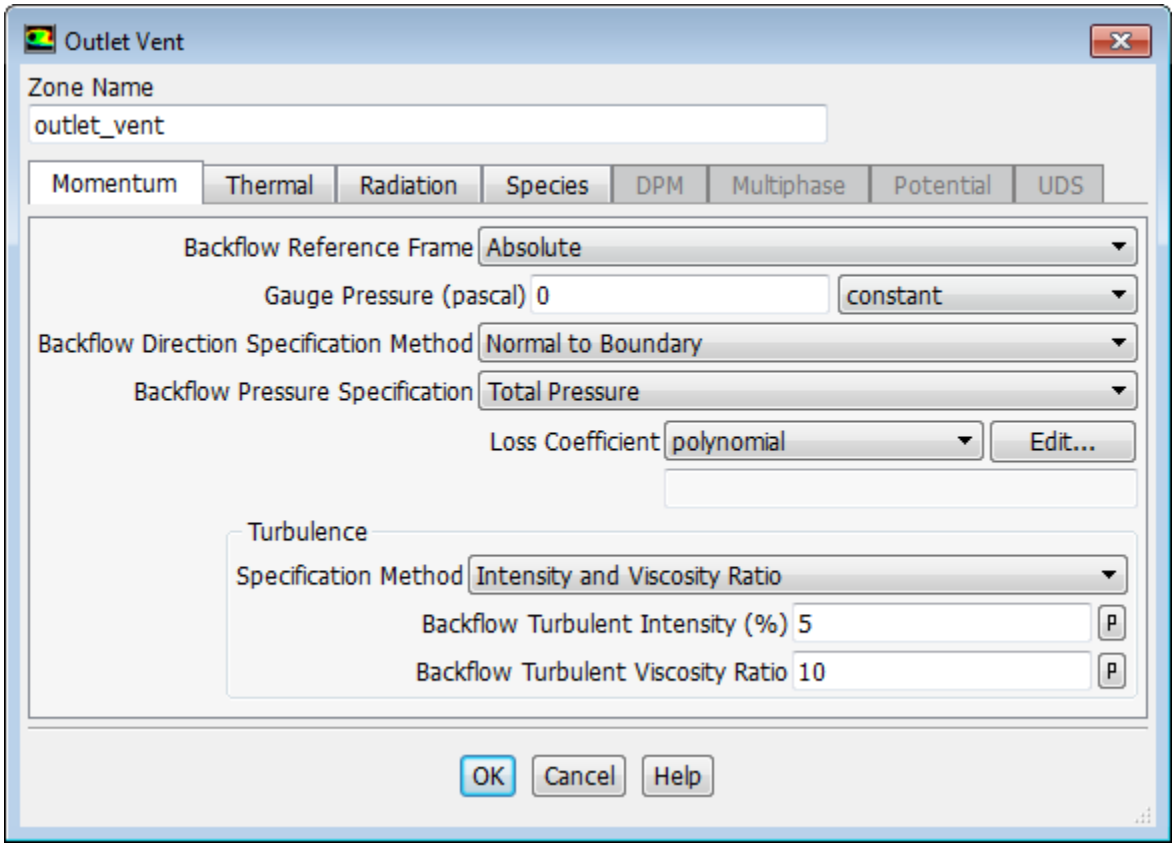
Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the outflow.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Participates in View Factor Calculation
specifies whether or not the outflow participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

37.8.12. Outlet Vent Dialog Box

The **Outlet Vent** dialog box sets the boundary conditions for an outlet vent zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Outlet Vent Boundaries (p. 353) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Momentum
contains the momentum parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Backflow Reference Frame
specify whether backflow temperature, pressure, and flow directions are in the **Absolute** or **Relative to the Adjacent Cell Zone** reference frame.

Gauge Pressure
sets the gauge pressure at the outlet boundary.

Backflow Direction Specification Method
specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** or **From Neighboring Cell** no inputs are required. See Defining the Flow Direction (p. 311) for information on specifying flow direction.

Coordinate System
contains a drop-down list for selecting the coordinate system. You can choose **Cartesian**, **Cylindrical**, or **Local Cylindrical**. This option is available only when **Direction Vector** is selected from the **Backflow Direction Specification Method** drop-down list.

X-, Y-, Z-Component of Flow Direction
allows you to specify the velocity components in x, y, and z directions respectively. This option is available when **Cartesian** is selected for the **Coordinate System**.

Radial-, Tangential-, Axial-Component of Flow Direction
set the direction of the flow at the boundary. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Backflow Pressure Specification
specifies how the pressure is calculated under backflow conditions. If you select **Static Pressure**, the **Gauge Pressure** is directly imposed as the boundary face pressure; if you select **Total Pressure**, the **Gauge Pressure** will be combined with a dynamic contribution that is based on the velocity in the adjacent cell zone.

Loss-Coefficient
sets the non-dimensional loss coefficient used to compute the pressure drop. See Specifying the Loss Coefficient (p. 355) for details.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Backflow Turbulent Kinetic Energy, Backflow Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Backflow Turbulent Kinetic Energy, Backflow Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Backflow Modified Turbulent Viscosity
sets the value of the backflow modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Backflow Turbulent Viscosity Ratio
sets the value of the backflow turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the backflow Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

Backflow UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the backflow Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Thermal
contains the thermal parameters.

Backflow Total Temperature
sets the total temperature of the inflow stream should the flow reverse direction

Radiation
contains the boundary conditions for the radiation model at the outlet vent.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Participates in Solar Ray Tracing
specifies whether or not the outlet vent participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the outlet vent.

Participates in View Factor Calculation
specifies whether or not the outlet vent participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.

Backflow Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Backflow Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction Specification Method
sets the method used to specify the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Backflow Volume Fraction
specifies the volume fraction of the secondary phase as a constant, profile, of UDF function.

From Neighboring Cell
calculates the volume fraction from the neighboring cells.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

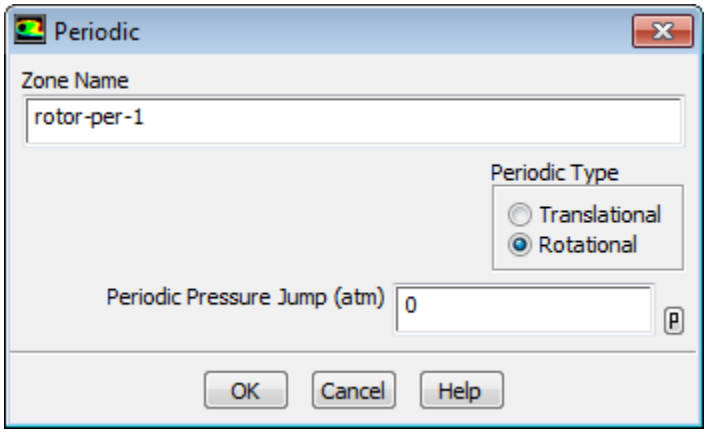
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Scalar n
specifies the value of the scalar.

37.8.13. Periodic Dialog Box

The **Periodic** dialog box sets the boundary conditions for a periodic zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs for Periodic Boundaries (p. 387) for details about the items below. See Periodic Flows (p. 582) for information about fully-developed periodic flow.



Controls

Zone Name
sets the name of the zone.

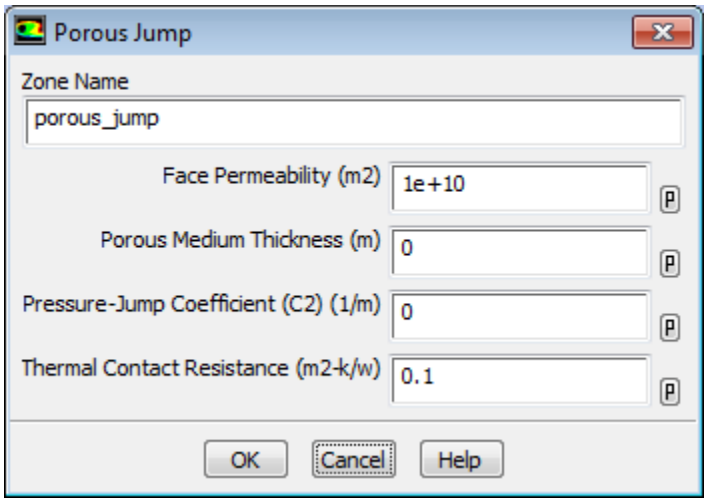
Periodic Type
indicates whether the periodicity of the domain is **Translational** or **Rotational**.

Periodic Pressure Jump
sets the pressure increase/decrease across the periodic boundary. (This item will not appear if the pressure-based (default) solver is used; it is relevant only for the density-based solvers.)

37.8.14. Porous Jump Dialog Box

The **Porous Jump** dialog box sets the boundary conditions for a porous-jump zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Porous Jump Boundary Conditions (p. 403) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name
sets the name of the zone.

Face Permeability
sets the face permeability coefficient (α in Equation 6.140 (p. 403)).

Porous Medium Thickness
sets the thickness of the porous medium (Δm).

Pressure-Jump Coefficient
sets the pressure-jump coefficient (C_2).

Thermal Contact Resistance
sets the thermal contact resistance.

Jump Adhesion
sets the adhesion method and contact angle.

Constrained-Two-Sided Adhesion
constrains the contact angle at the porous jump, When this option is disabled then the forced two-sided adhesion treatment is in effect. See Jump Adhesion for more information.

Contact Angle
is the contact angle at the porous jump.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

interior
allows the particles to pass through the boundary.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Solar Boundary Conditions
contains the settings for solar ray tracing. This group box is available only if you select **Solar Ray Tracing** from the **Model** list in the **Solar Load** group box of the **Radiation Model** dialog box. See Solar Ray Tracing (p. 900) for details.

Participates in Solar Ray Tracing
specifies whether or not the porous jump participates in solar ray tracing.

Absorptivity
contains the settings that define the absorptivity of the porous jump.

Direct Visible
specifies a multiplier (ranging from 0 to 1) that is applied to the visible portion of the direct solar radiation spectrum to account for the absorption of the porous jump.

Direct IR
specifies a multiplier (ranging from 0 to 1) that is applied to the infrared portion of the direct solar radiation spectrum to account for the absorption of the porous jump.

Transmissivity
contains the settings that define the transmissivity of the porous jump.

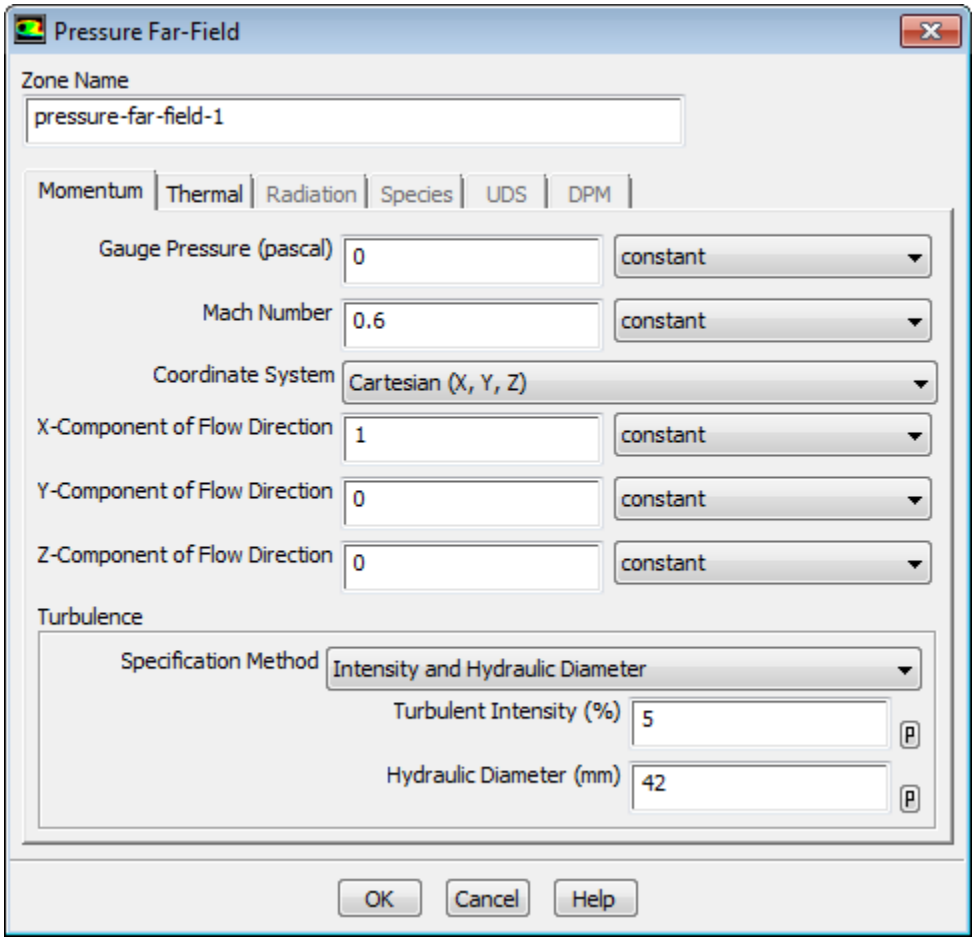
Direct Visible
specifies a multiplier (ranging from 0 to 1) that is applied to the visible portion of the direct solar radiation spectrum to account for the transmissivity of the porous jump.

Direct IR
specifies a multiplier (ranging from 0 to 1) that is applied to the infrared portion of the direct solar radiation spectrum to account for the transmissivity of the porous jump.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.8.15. Pressure Far-Field Dialog Box

The **Pressure Far-Field** dialog box sets the boundary conditions for a pressure far-field zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Pressure Far-Field Boundaries (p. 347) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Momentum
contains the momentum parameters.

Gauge Pressure
sets the far-field gauge static pressure.

Mach Number
sets the far-field Mach number. The Mach number can be subsonic, sonic, or supersonic.

Coordinate System
allows you to select a **Cartesian**, **Cylindrical**, or **Local Cylindrical** coordinate system. This option is available only for 3D geometry.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

X-, Y-, Z-Component of Flow Direction
set the far-field flow direction. These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial-, Tangential-, Axial-Component of Flow Direction
set the far-field flow direction. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Turbulent Intensity, Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Turbulent Intensity, Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity, Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity
sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio
sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Turbulence Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reynolds-Stress Specification Method
specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Thermal
contains the thermal parameters.

Temperature
sets the far-field static temperature.

Radiation
contains the boundary conditions for the radiation model at the pressure far-field zone.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the pressure far-field zone participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the pressure far-field zone.

Participates in View Factor Calculation
specifies whether or not the pressure far-field zone participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. (These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.)

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

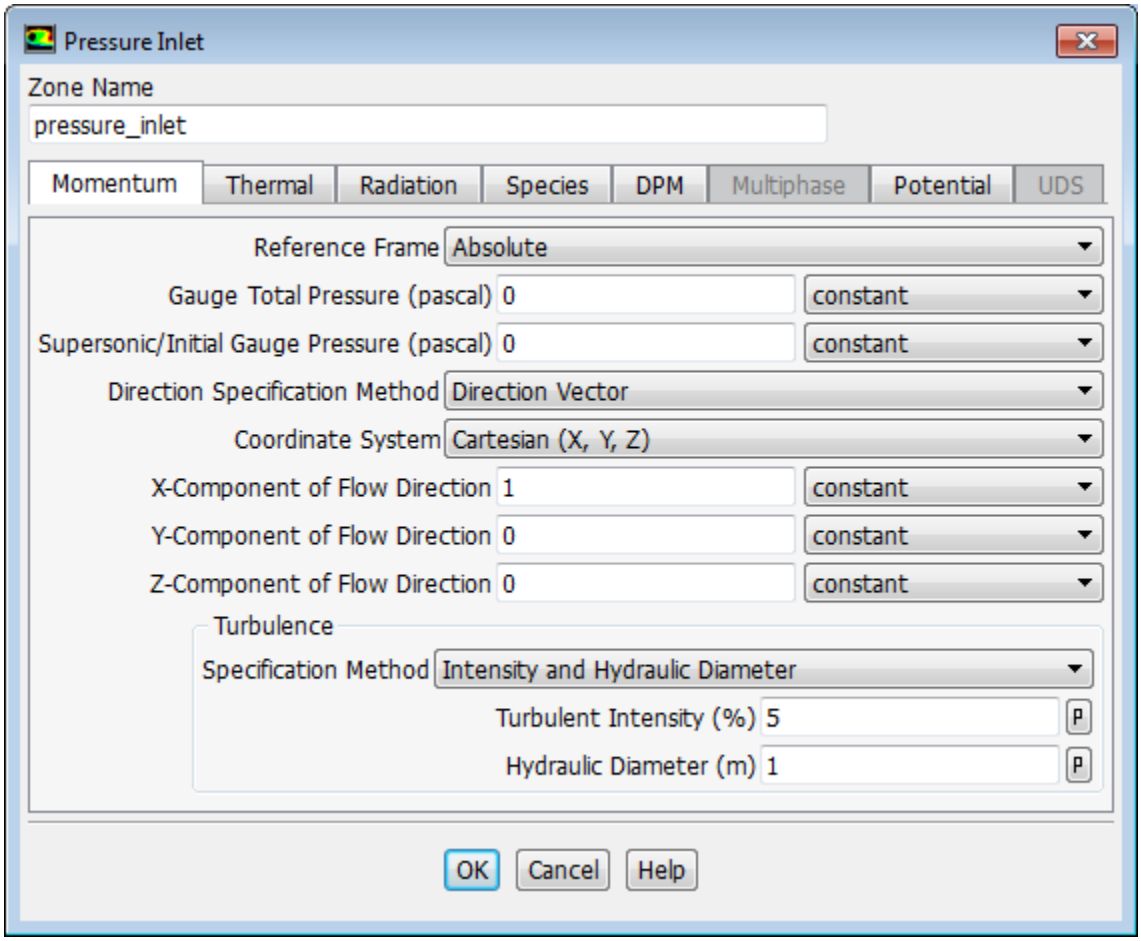
user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.8.16. Pressure Inlet Dialog Box

The **Pressure Inlet** dialog box sets the boundary conditions for a pressure inlet zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Pressure Inlet Boundaries (p. 308) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Momentum
contains the momentum parameters.

Reference Frame
specifies the reference frame for the pressure inlet. If the cell zone adjacent to the pressure inlet is moving, you can choose to specify the total temperature, total pressure, and velocity components as **Relative to Adjacent CellZone** or **Absolute** in the **Reference Frame** drop-down list.

Gauge Total Pressure
sets the gauge total (or stagnation) pressure of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total pressure.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Supersonic/Initial Gauge Pressure
sets the static pressure on the boundary when the flow becomes (locally) supersonic. It is also used to compute initial values for pressure, temperature, and velocity if the pressure inlet boundary condition is selected for computing initial values (see Initializing the Entire Flow Field Using Standard Initialization (p. 1591)).

Direction Specification Method
specifies the method you will use to define the flow direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** no inputs are required. See Defining the Flow Direction (p. 311) for information on specifying flow direction.

Coordinate System
specifies whether **Cartesian**, **Cylindrical**, **Local Cylindrical**,or **Local Cylindrical Swirl** vector components will be defined. This item will appear only for 3D cases in which you have selected **Direction Vector** as the **Direction Specification Method**.

X,Y,Z-Component of Flow Direction
set the direction of the flow at the inlet boundary. These items will appear if the selected **Coordinate System** is **Cartesian** or the model is 2D non-axisymmetric.

Radial, Tangential, Axial Component of Flow Direction
set the direction of the flow at the inlet boundary. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Radial-, Axial-Component of Flow Direction, Tangential-Velocity
appear for a 3D **Local Cylindrical Swirl** coordinate system.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical (swirl) coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical (swirl) coordinate system.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Turbulent Intensity, Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Turbulent Intensity, Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity, Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity
sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio
sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Acoustic Wave Model
contains settings for treatment of acoustic pressure waves at the boundary.

Off
disables special treatment of acoustic pressure waves at the boundary.

Non Reflecting
enables the general non-reflecting boundary condition treatment described in General Non-Reflecting Boundary Conditions (p. 416).

Impedance
enables the impedance boundary condition treatment described in Impedance Boundary Conditions (p. 422).

Transparent Flow Forcing
enables the transparent flow forcing boundary condition described in Transparent Flow Forcing Boundary Conditions (p. 425).

Impedance Parameters
contains the parameters for the impedance boundary condition treatment. For details refer to Using the Impedance Boundary Condition (p. 424).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transparent Flow Forcing Parameters
contains the parameters for the transparent flow forcing boundary condition treatment. For details refer to Using the Transparent Flow Forcing Boundary Condition (p. 426).

Thermal
contains the thermal parameters.

Total Temperature
sets the total temperature of the inflow stream. If you are using moving reference frames, see Defining Total Pressure and Temperature (p. 310) for information about relative and absolute total temperature.

Radiation
contains the boundary conditions for the radiation model at the pressure inlet.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the pressure inlet participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the pressure inlet.

Participates in View Factor Calculation
specifies whether or not the pressure inlet participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. (These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.)

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DPM

contains the discrete phase parameters.

Discrete Phase BC Type

sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect

rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap

terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape

reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet

indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined

specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function

sets the user-defined function from the drop-down list.

Multiphase

contains the multiphase parameters.

Granular Temperature

specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction

specifies the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Potential

displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition

is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS

contains the UDS parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

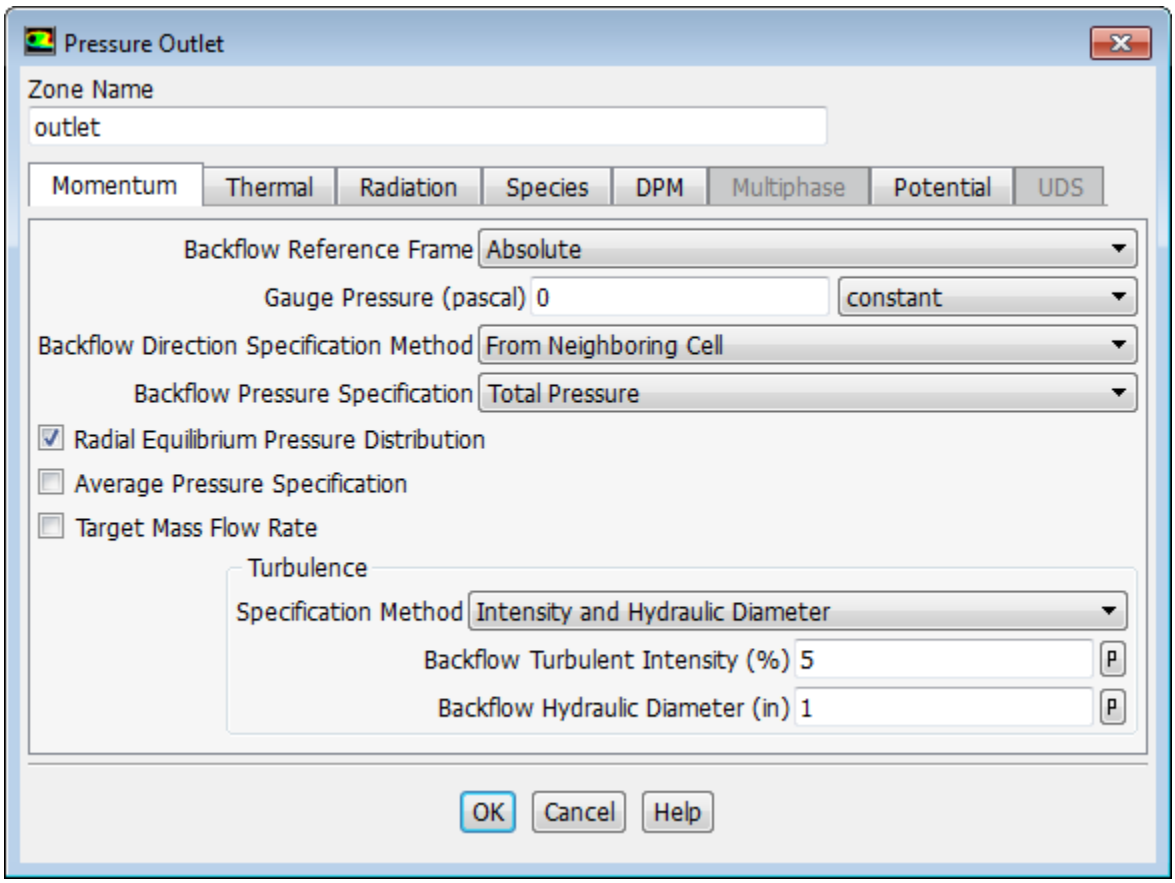
User Scalar n
specifies whether the scalar is a specified flux or a specified value.

User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

37.8.17. Pressure Outlet Dialog Box

The **Pressure Outlet** dialog box sets the boundary conditions for a pressure outlet zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Pressure Outlet Boundaries (p. 338) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Momentum
contains the momentum parameters.

Backflow Reference Frame
specify whether backflow temperature, pressure, and flow directions are in the **Absolute** or **Relative to the Adjacent Cell Zone** reference frame.

Gauge Pressure
sets the gauge pressure at the outflow boundary.

Backflow Direction Specification Method
sets the direction of the inflow stream should the flow reverse direction. If you choose **Direction Vector**, you will define the flow direction components, and if you choose **Normal to Boundary** or **From Neighboring Cell**, no inputs are required. See Inputs at Pressure Outlet Boundaries (p. 338) for information on specifying flow direction.

Coordinate System
contains a drop-down list for selecting the coordinate system. You can choose **Cartesian**, **Cylindrical**, or **Local Cylindrical**. This option is available only when **Direction Vector** is selected from the **Backflow Direction Specification Method** drop-down list.

X-, Y-, Z-Component of Flow Direction
allows you to specify the velocity components in x, y, and z directions respectively. This option is available when **Cartesian** is selected for the **Coordinate System**.

Radial-, Tangential-, Axial-Component of Flow Direction
set the direction of the flow at the boundary. These items will appear for 2D axisymmetric cases, or for 3D cases for which the selected **Coordinate System** is **Cylindrical** or **Local Cylindrical**.

Backflow Pressure Specification
specifies how the pressure is calculated under backflow conditions. When the NRBC option is not enabled, if you select **Static Pressure**, the **Gauge Pressure** is directly imposed as the boundary face pressure; if you select **Total Pressure**, the **Gauge Pressure** will be combined with a dynamic contribution that is based on the velocity in the adjacent cell zone. For NRBCs, if you select **Static Pressure**, the **Gauge Pressure** is directly imposed as the pressure at infinity; if you select **Total Pressure**, the pressure at infinity is a calculated value that is based on the **Gauge Pressure**.

Radial Equilibrium Pressure Distribution
enables the radial equilibrium pressure distribution. See Defining Static Pressure (p. 339) for details.

This item appears only for 3D and axisymmetric swirl solvers.

Average Pressure Specification
allows the pressure along the outlet boundary to vary, but maintain an average equivalent to the specified value in the **Gauge Pressure** input field. In this boundary implementation, the pressure variation provides a low level of non-reflectivity. For more details, see Calculation Procedure at Pressure Outlet Boundaries (p. 342).

Note

The **Average Pressure Specification** option is not available if the **Radial Equilibrium Pressure Distribution** option is enabled.

Target Mass Flow Rate
allows you to set mass flow rate as a boundary condition at the outlet.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Target Mass Flow
allows you to specify the flow as either a constant value or a user-defined function.

Upper Limit of Absolute Pressure, Lower Limit of Absolute Pressure
specifies the range of the pressure limits, which have different pressure variations on different boundaries. The upper and lower pressure limits can be specified as a constant or a profile.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Backflow Turbulent Kinetic Energy, Backflow Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Backflow Turbulent Kinetic Energy, Backflow Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Turbulent Viscosity Ratio
set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Backflow Turbulent Intensity, Backflow Hydraulic Diameter
set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Backflow Modified Turbulent Viscosity
sets the value of the backflow modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Backflow Turbulent Viscosity Ratio
sets the value of the backflow turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Reynolds-Stress Specification Method
specifies which method will be used to determine the backflow Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Backflow UU, VV, WW, UV, VW, UW Reynolds Stresses
specify the backflow Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Acoustic Wave Model
contains settings for treatment of acoustic pressure waves at the boundary.

Off
disables special treatment of acoustic pressure waves at the boundary.

Non Reflecting
enables the general non-reflecting boundary condition treatment described in General Non-Reflecting Boundary Conditions (p. 416).

Impedance
enables the impedance boundary condition treatment described in Impedance Boundary Conditions (p. 422).

Transparent Flow Forcing
enables the transparent flow forcing boundary condition described in Transparent Flow Forcing Boundary Conditions (p. 425).

Non Reflecting Parameters
contains settings for the non-reflecting boundary condition treatment.

Exit Pressure Specification
defines how the pressure is calculated. For **Pressure at Infinity**, the pressure at the boundary relaxes toward the **Gauge Pressure** at infinity; for **Average Boundary Pressure**, an effort is made to force the average pressure on the boundary to approach the **Gauge Pressure** value.

Impedance Parameters
contains the parameters for the impedance boundary condition treatment. For details refer to Using the Impedance Boundary Condition (p. 424).

Transparent Flow Forcing Parameters
contains the parameters for the transparent flow forcing boundary condition treatment. For details refer to Using the Transparent Flow Forcing Boundary Condition (p. 426).

Thermal
contains the thermal parameters.

Backflow Total Temperature
sets the total temperature of the inflow stream should the flow reverse direction

Radiation
contains the boundary conditions for the radiation model at the pressure outlet.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the pressure outlet participates in solar ray tracing.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the pressure outlet.

Participates in View Factor Calculation
specifies whether or not the pressure outlet participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model.)

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.

Backflow Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6:"Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Backflow Granular Temperature
specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles.

Volume Fraction Specification Method
sets the method used to specify the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Backflow Volume Fraction
specifies the volume fraction of the secondary phase as a constant, profile, of UDF function.

From Neighboring Cell
calculates the volume fraction from the neighboring cells.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

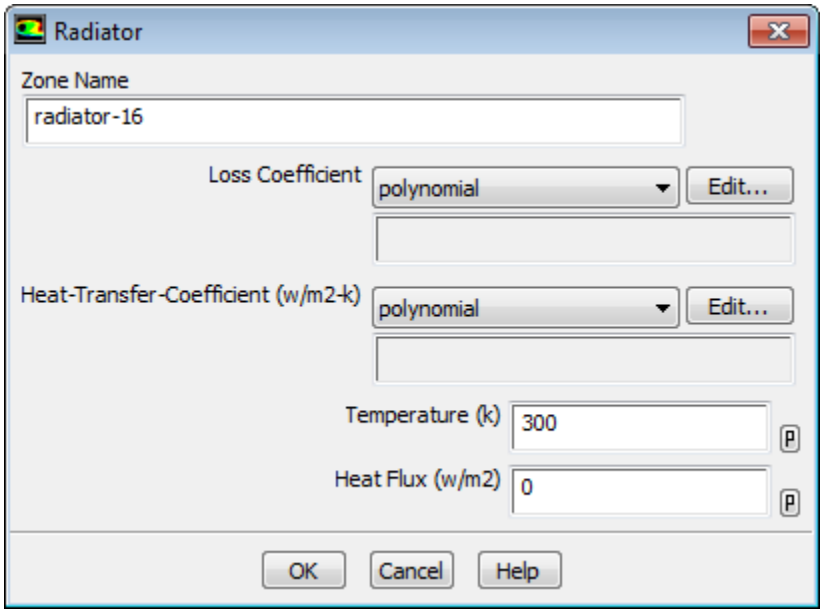
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.8.18. Radiator Dialog Box

The **Radiator** dialog box sets the boundary conditions for a radiator model zone. It is opened from the Boundary Conditions Task Page (p. 2389). See User Inputs for Radiators (p. 398) for details about the items below.



Controls

Zone Name
sets the name of the zone.

Loss Coefficient
specifies the loss coefficient as a constant value or as a polynomial, piecewise-linear, or piecewise-polynomial function of velocity. See Defining the Pressure Loss Coefficient Function (p. 399) for details.

Heat-Transfer-Coefficient
specifies the heat-transfer coefficient as a constant value or as a polynomial, piecewise-linear, or piecewise-polynomial function of velocity. See Defining the Heat Flux Parameters (p. 401) for details.

Temperature
sets the temperature used to compute heat flux from the radiator using the **Heat-Transfer-Coefficient**. If **Temperature** is absolute zero, the **Heat Flux** condition is used instead.

Heat Flux
sets the heat flux at the radiator surface (used only when **Temperature** is absolute zero).

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

interior
allows the particles to pass through the boundary.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

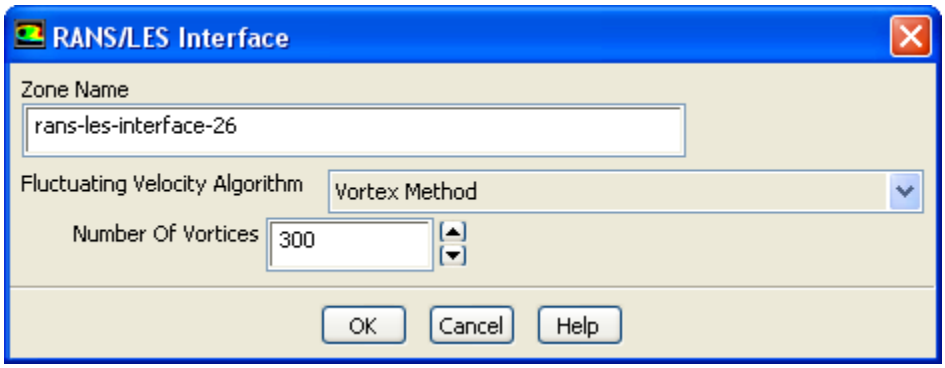
wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

37.8.19. RANS/LES Interface Dialog Box

The **RANS/LES Interface** dialog box can be used to create artificial resolved turbulence (fluctuation/perturbations) at the interface where the flow proceeds from the RANS zone into the LES zone of the computational domain for Embedded LES turbulent flows. It is opened from the Boundary Conditions Task Page (p. 2389). See Setting Up the Embedded Large Eddy Simulation (ELES) Model (p. 793) for more information about RANS/LES interfaces.



Controls

Zone Name
sets the name of the RANS/LES interface.

Fluctuating Velocity Algorithm
displays the methods for generating fluctuating velocity components at the RANS/LES interface. Available options include:

- No Perturbations

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Spectral Synthesizer
- Vortex Method

Number of Vortices

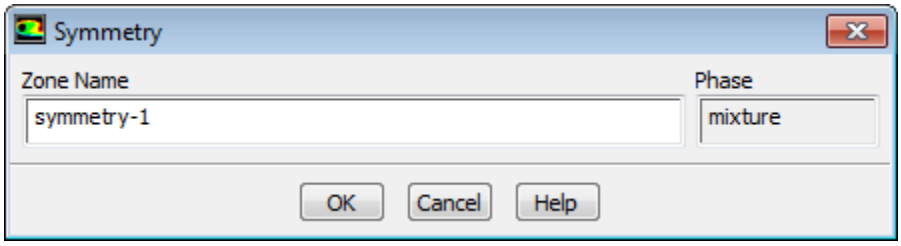
displays the amount of vortices that the selected fluctuating velocity method distributes randomly over the face zone and uses to generate turbulent fluctuations (available for the Vortex Method only).

Important

The RANS/LES 'interface' can either be an interior zone (that has been assigned to be a **rans-les-interface** zone), or it can be a non-conformal interface. If it is a non-conformal interface, then you need to identify the name of the non-conformal interface's "interior" zone (for example, using the Mesh Interfaces Dialog Box (p. 2732)), and then go to that zone in the **Boundary Conditions** task page.

37.8.20. Symmetry Dialog Box

The **Symmetry** dialog box can be used to modify the name of a symmetry zone; there are no conditions to be set. It is opened from the Boundary Conditions Task Page (p. 2389). See Symmetry Boundary Conditions (p. 384) for information about symmetry boundaries.



Controls

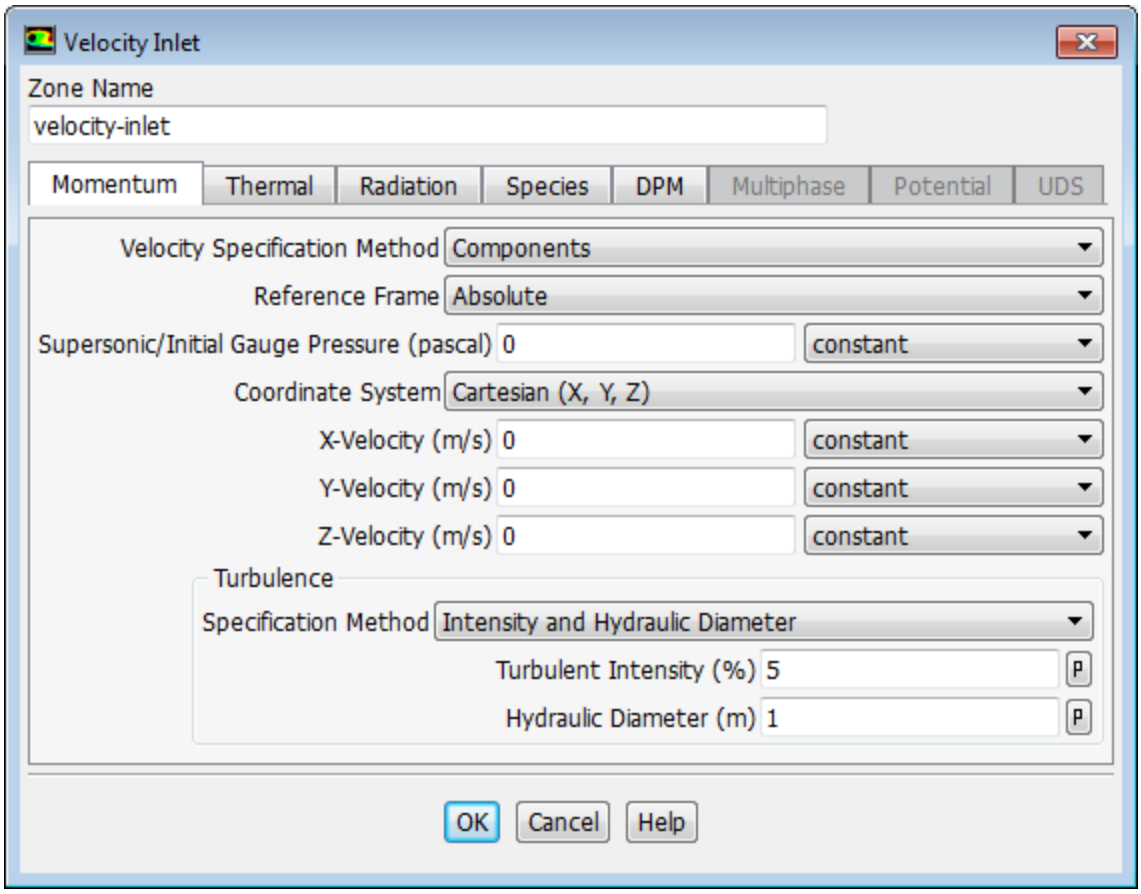
Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item is available only for multiphase flows.

37.8.21. Velocity Inlet Dialog Box

The **Velocity Inlet** dialog box sets the boundary conditions for a velocity inlet zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Velocity Inlet Boundaries (p. 317) for details about defining the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item appears if the VOF, mixture, or Eulerian multiphase model is being used.

Open Channel Wave BC
allows you to set specific parameters for a particular boundary for open channel wave boundaries. This is available when the volume of fluid multiphase model is selected.

Momentum
contains the momentum parameters.

Velocity Specification Method
sets the method used to define the inflow velocity.

Flow Direction Specification Method
sets the method used to define the direction of flow of the wave. This is available when you enable the **Open Channel Wave BC** option.

Magnitude and Direction
allows specification in terms of a **Velocity Magnitude** and **Flow-Direction**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Components
allows specification in terms of the Cartesian, cylindrical, or local cylindrical velocity components.

Magnitude, Normal to Boundary
allows specification of a **Velocity Magnitude** normal to the boundary.

Reference Frame
specifies relative or absolute velocity inputs. You can choose to enter **Absolute** velocities or velocities **Relative to Adjacent Cell Zone**. If you are not using moving reference frames, both options are equivalent, so you need not choose.

Uniform Flow Velocity Magnitude
is the flow velocity, specified as a constant or a parameter.

Coordinate System
specifies whether **Cartesian**, **Cylindrical**, or **Local Cylindrical** velocities will be defined. This item will appear only for 3D cases in which you have selected **Magnitude and Direction** or **Components** as the **Velocity Specification Method**.

X-, Y-, Z-Velocity
set the components of the velocity vector at the inflow boundary. These items will appear for 2D non-axisymmetric models, or for 3D models if you select the **Components** option as the **Velocity Specification Method** and **Cartesian** as the **Coordinate System**.

Radial-, Tangential-, Axial-Velocity
set the components of the velocity vector at the inflow boundary. These items will appear for 3D models if you select the **Components** option as the **Velocity Specification Method** and **Cylindrical** or **Local Cylindrical** as the **Coordinate System**.

Axial-, Radial-, Swirl-Velocity
set the components of the velocity vector at the inflow boundary. These items will appear for 2D axisymmetric models.

Important

Swirl-Velocity will appear only for 2D axisymmetric swirl models.

Angular Velocity
specifies the angular velocity Ω for a 3D flow. This item will appear for a 3D model if you select the **Components** option as the **Velocity Specification Method** and **Cylindrical** or **Local Cylindrical** as the **Coordinate System**.

Swirl Angular Velocity
specifies the swirl angular velocity Ω for an axisymmetric swirling flow. This item will appear for an axisymmetric swirl model if you choose **Components** as the **Velocity Specification Method**.

Velocity Magnitude
sets the magnitude of the velocity vector at the inflow boundary. This item will appear if you select the **Magnitude and Direction** or **Magnitude, Normal to Boundary** option as the **Velocity Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

X-, Y-, Z-Component of Flow Direction
set the direction of the velocity vector at the inflow boundary. These items will appear for 2D non-axisymmetric models if you select the **Magnitude and Direction** option as the **Velocity Specification Method**, or for 3D models if you select the **Magnitude and Direction** option as the **Velocity Specification Method** and **Cartesian** as the **Coordinate System**.

Radial-, Tangential-, Axial-Component of Flow Direction
set the direction of the velocity vector at the inlet boundary. These items will appear for 3D models if you select the **Magnitude and Direction** option as the **Velocity Specification Method** and **Cylindrical** or **Local Cylindrical** as the **Coordinate System**, or for 2D axisymmetric models.

Important

Tangential-Velocity will appear only for 2D axisymmetric swirl models.

Axis Origin
sets the **X**, **Y**, and **Z** coordinates of the origin of the local cylindrical coordinate system.

Axis Direction
sets the **X**, **Y**, and **Z** components of the direction of the local cylindrical coordinate system.

Outflow Gauge Pressure
specifies the pressure to be used as the pressure outlet condition if flow exits the domain at any face on the velocity inlet boundary. (Note that this effect is similar to that of the "velocity far-field" boundary that was available in RAMPANT 3.)

This item appears only for the density-based solvers.

Turbulence
contains the turbulence parameters.

Specification Method
specifies which method will be used to define the turbulence parameters. You can choose **K and Epsilon** (k- ε models and RSM only), **K and Omega** (k- ω models only), **Intensity and Length Scale**, **Intensity and Viscosity Ratio**, **Intensity and Hydraulic Diameter**, **Modified Turbulent Viscosity** (Spalart-Allmaras model only), or **Turbulent Viscosity Ratio** (Spalart-Allmaras model only). See Determining Turbulence Parameters (p. 303) for information about the inputs for each of these methods. (This item will appear only for turbulent flow calculations.)

Turbulent Kinetic Energy, Turbulent Dissipation Rate
set values for the turbulence kinetic energy k and its dissipation rate ε. These items will appear if you choose **K and Epsilon** as the **Specification Method**.

Turbulent Kinetic Energy, Specific Dissipation Rate
set values for the turbulence kinetic energy k and its specific dissipation rate ω. These items will appear if you choose **K and Omega** as the **Specification Method**.

Turbulent Intensity, Turbulent Length Scale
set values for turbulence intensity I and turbulence length scale ℓ. These items will appear if you choose **Intensity and Length Scale** as the **Specification Method**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Turbulent Intensity, Turbulent Viscosity Ratio

set values for turbulence intensity I and turbulent viscosity ratio μ_t / μ. These items will appear if you choose **Intensity and Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity, Hydraulic Diameter

set values for turbulence intensity I and hydraulic diameter L. These items will appear if you choose **Intensity and Hydraulic Diameter** as the **Specification Method**.

Modified Turbulent Viscosity

sets the value of the modified turbulent viscosity $\tilde{\nu}$. This item will appear if you choose **Modified Turbulent Viscosity** as the **Specification Method**.

Turbulent Viscosity Ratio

sets the value of the turbulent viscosity ratio μ_t / μ. This item will appear if you choose **Turbulent Viscosity Ratio** as the **Specification Method**.

Turbulent Intensity

sets the value of the turbulence intensity I for the LES model.

Reynolds-Stress Specification Method

specifies which method will be used to determine the Reynolds stress boundary conditions when the Reynolds stress turbulence model is used. You can choose either **K or Turbulent Intensity** or **Reynolds-Stress Components**. If you choose the former, ANSYS Fluent will compute the Reynolds stresses for you. If you choose the latter, you will explicitly specify the Reynolds stresses yourself. See Reynolds Stress Model (p. 808) for details. (This item will appear only for RSM turbulent flow calculations.)

UU, VV, WW, UV, VW, UW Reynolds Stresses

specify the Reynolds stress components when **Reynolds-Stress Components** is chosen as the **Reynolds-Stress Specification Method**.

Acoustic Wave Model

contains settings for treatment of acoustic pressure waves at the boundary.

Off

disables special treatment of acoustic pressure waves at the boundary.

Non Reflecting

enables the general non-reflecting boundary condition treatment described in General Non-Reflecting Boundary Conditions (p. 416).

Impedance

enables the impedance boundary condition treatment described in Impedance Boundary Conditions (p. 422).

Transparent Flow Forcing

enables the transparent flow forcing boundary condition described in Transparent Flow Forcing Boundary Conditions (p. 425).

Impedance Parameters

contains the parameters for the impedance boundary condition treatment. For details refer to Using the Impedance Boundary Condition (p. 424).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transparent Flow Forcing Parameters
contains the parameters for the transparent flow forcing boundary condition treatment. For details refer to Using the Transparent Flow Forcing Boundary Condition (p. 426).

Thermal
contains the thermal parameters.

Temperature
specifies the static temperature of the flow.

Radiation
contains the boundary conditions for the radiation model at the velocity inlet.

External Black Body Temperature Method, Internal Emissivity
set the radiation boundary conditions when you are using the P-1, DTRM, DO, S2S, or MC models for radiation heat transfer. See Defining Boundary Conditions for Radiation (p. 869) for details.

Participates in Solar Ray Tracing
specifies whether or not the velocity inlet participates in solar ray tracing.

Solar Transmissivity Factor
specifies a multiplier (ranging from 0 to 1) that is applied to the solar irradiation entering the domain through the velocity inlet.

Participates in View Factor Calculation
specifies whether or not the velocity inlet participates in the view factor calculation as part of the S2S radiation model. This parameter is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters.

Specify Species in Mole Fractions
allows you to specify the species in mole fractions rather than mass fractions.

Species Mass Fractions
contains inputs for the mass fractions of defined species. See Defining Cell Zone and Boundary Conditions for Species (p. 990) for details about these inputs. These items will appear only if you are modeling non-reacting multi-species flow or you are using the finite-rate reaction formulation.

Mean Mixture Fraction, Mixture Fraction Variance
set inlet values for the PDF mixture fraction and its variance. These items will appear only if you are using the non-premixed or partially premixed combustion model.

Secondary Mean Mixture Fraction, Secondary Mixture Fraction Variance
set inlet values for the secondary mixture fraction and its variance. (These items will appear only if you are using the non-premixed or partially premixed combustion model with two mixture fractions.)

Progress Variable
sets the value of the progress variable for premixed turbulent combustion. See Setting Boundary Conditions for the Progress Variable (p. 1094) for details.

This item will appear only if the premixed or partially premixed combustion model is used.

DPM
contains the discrete phase parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Discrete Phase BC Type
sets the way that the discrete phase behaves with respect to the boundary. This item appears when one or more injections have been defined.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficient of restitution. (See Particle Reflection at Wall in the *Fluent Theory Guide*.)

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6: "Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Discrete Phase BC Function
sets the user-defined function from the drop-down list.

Multiphase
contains the multiphase parameters.

Volume Fraction
specifies the volume fraction of the secondary phase selected in the Boundary Conditions Task Page (p. 2389). This section of the dialog box will appear when one of the multiphase models is being used. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

Secondary Phase for Inlet
specifies the secondary phase to which the parameters are applied. In case of a three-phase flow, select the corresponding secondary phase from this list.

Wave BC Options
allows you to choose between **Shallow Waves**, **Shallow/Intermediate Waves** or **Short Gravity Waves**. Information about the two types of waves is available in Open Channel Wave Boundary Conditions in the Theory Guide.

Free Surface Level
is determined by using the absolute value of height from the free surface to the origin in the direction of gravity and applying the correct sign based on whether the free surface level is above (positive) or below (negative) the origin.

Bottom Level
is valid for shallow and intermediate waves. The bottom level is used for calculating the liquid height.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reference Wave Direction
is the direction of wave propagation for a zero wave heading angle.

Wave Modeling Options
determines whether to use wave theory or a wave spectrum to model waves in the shallow/intermediate and short gravity wave regimes.

Number of Waves
specifies the number of waves you are defining when modeling waves using wave theory.

Wave Theory
allows you to choose from **First Order Airy** (the default), **Second Order Stokes**, **Third Order Stokes**, **Fourth Order Stokes**, and **Fifth Order Stokes** for shallow/intermediate waves and short gravity waves. For shallow waves, you can choose between **Fifth Order Solitary** and **Fifth Order Cnoidal**. Information about the types of wave theory is available in Open Channel Wave Boundary Conditions in the Theory Guide.

Wave Height
is the height difference between a wave crest to the neighboring trough.

Since a solitary wave does not have troughs, the wave height is the distance between a wave crest to mean free surface level.

Wave Length
is the wave length of the shallow wave or short gravity wave.

Inlet Offset Distance
is the translational distance from the reference point origin in the reference wave propagation direction. This option is used to generate a wave from a location other than the reference frame origin.

Phase Difference
is the phase difference between one wave and another.

Wave Heading Angle
is the angle between the direction of the wavefront and the reference wave direction, in the plane of the flow surface. In 2D, there are only two possibilities, zero degrees when the wave is in the reference wave direction, and 180 degrees when the wave is in the opposite direction.

Frequency Spectrum Method
specifies the spectrum to use. You can select **Pierson-Moskowitz** (appropriate for fully-developed seas), **Jonswap** (appropriate for fetch-limited seas), or **TMA** (appropriate for fetch-limited, finite-depth seas).

Peak Shape Parameter
controls the shape and amplitude of the frequency peak in the **Jonswap** and **TMA** formulations. This corresponds to γ in Equation 17.100 in the *Fluent Theory Guide*.

Significant Wave Height
is the mean wave height of the largest 1/3 of waves. This corresponds to H_s in Equation 17.99 in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Peak Wave Frequency
is the wave frequency corresponding to the highest wave energy. This corresponds to ω_p in Equation 17.99 and Equation 17.100 in the *Fluent Theory Guide*. ω_p can be expressed in terms of the peak wave period, T_p, as $\omega_p = {}^{2\pi}/_{T_p}$.

Minimum/Maximum Wave Frequency
specify the frequency range for the spectrum. Note that the **Peak Wave Frequency** must fall in between **Minimum Wave Frequency** and **Maximum Wave Frequency**.

Number of Frequency Components
specifies the number of components into which the frequency spectrum is divided.

Direction Spreading Method
specifies the method to use for specifying the directional spreading characteristics. You can choose **Unidirectional** (for long-crested waves), **Frequency Independent Cosine Function** (for short-crested waves where the directional component does not depend on frequency), and **Frequency Dependant Hyperbolic Function** (for short-crested waves where the directional component depends on frequency).

Frequency Independent Cosine Exponent
specifies the exponent in the Frequency Independent Cosine Function formulation. This corresponds to s in Equation 17.104 in the *Fluent Theory Guide*.

Mean Wave Heading Angle
specifies the principal wave heading direction.

Angular Spread
specifies the deviation from the mean wave direction for calculating the angular range.

Number of Angular Components
specifies the number of components into which the angular range is divided.

Potential
displays the boundary conditions for the electric potential field. This tab is available only if you have enabled either the **Electric Potential model** or the **Electrochemical** reaction model in the Species Dialog Box (p. 2332).

Potential Boundary Condition
is a drop-down list of available potential boundary condition types: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

UDS
contains the UDS parameters.

User-Defined Scalar Boundary Condition
appears only if user-defined scalars are specified.

User Scalar n
specifies whether the scalar is a specified flux or a specified value.

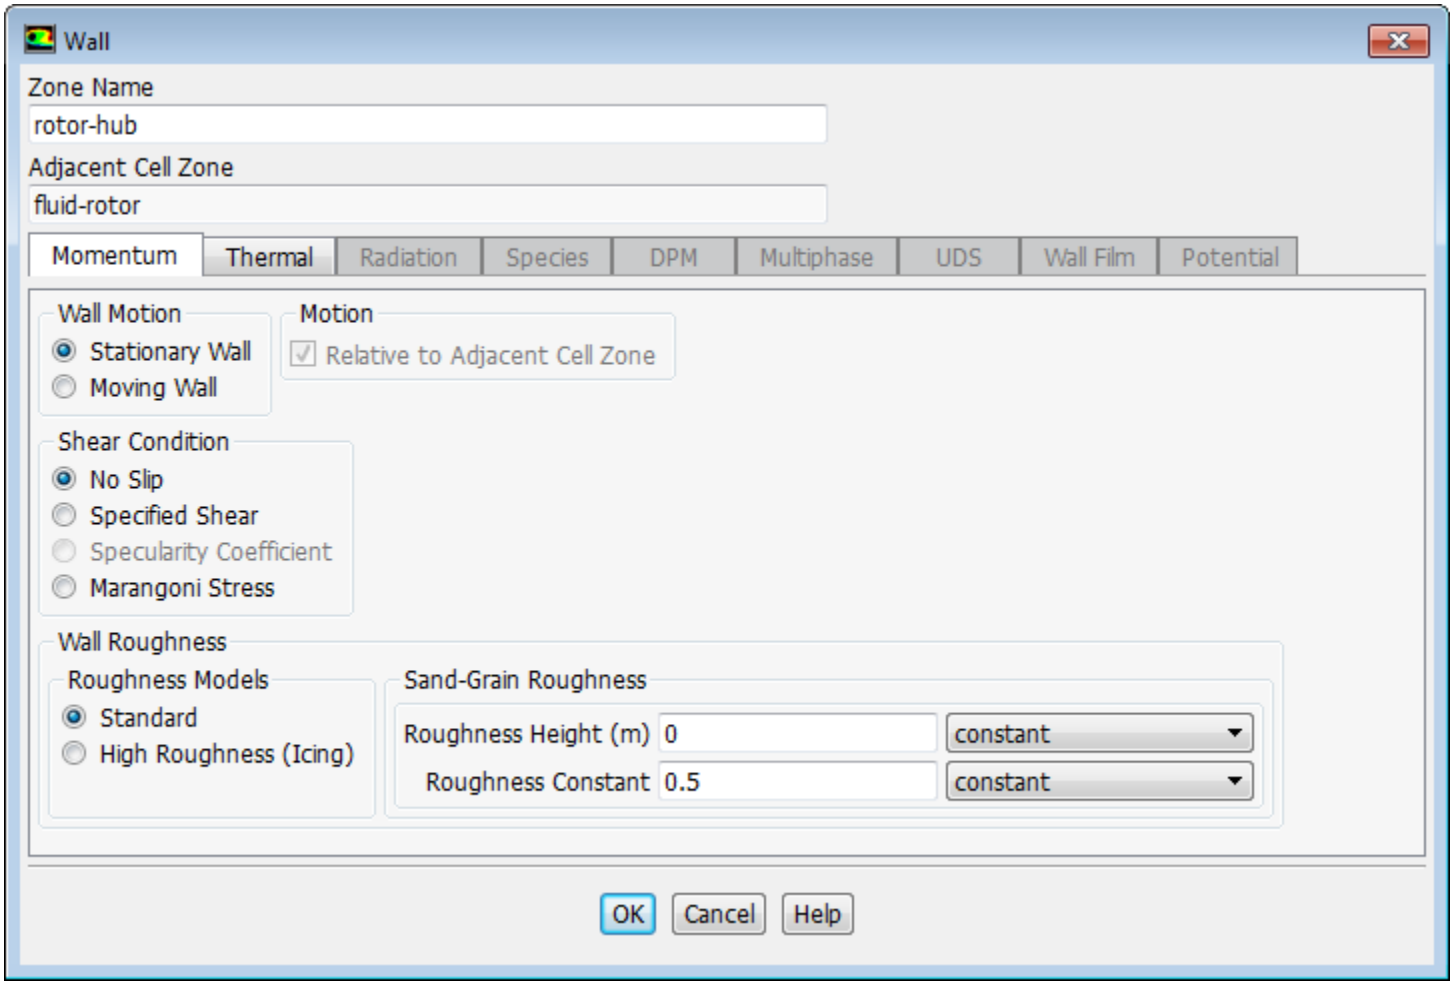
User-Defined Scalar Boundary Value
appears only if user-defined scalars are specified.

User Scalar n
specifies the value of the scalar.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.8.22. Wall Dialog Box

The **Wall** dialog box sets the boundary conditions for a wall zone. It is opened from the Boundary Conditions Task Page (p. 2389). See Inputs at Wall Boundaries (p. 358) for details about defining the items below.



Controls

Zone Name
sets the name of the zone.

Phase
displays the name of the phase. This item appears if the VOF, mixture, or Eulerian multiphase model is being used.

Adjacent Cell Zone
shows the name of the cell zone adjacent to the wall. (This is for informational use only; you cannot edit this field.)

Momentum
displays the momentum boundary conditions.

Wall Motion
contains options for specifying whether or not the wall is moving.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Stationary Wall
specifies that the wall is not moving relative to the adjacent cell zone.

Moving Wall
enables specification of the tangential wall motion. Tangential wall motion is applicable only to viscous flows. Since the inviscid slip condition decouples the tangential wall velocity from the governing equations, tangential wall motion has no effect on inviscid flow.

Motion
contains inputs related to wall motion. See Velocity Conditions for Moving Walls (p. 359) for details.

Relative to Adjacent Cell Zone
enables the specification of a wall velocity relative to the velocity of the adjacent cell zone.(If the adjacent cell zone is not moving, this is equivalent to **Absolute**.)

Absolute
enables the specification of an absolute wall velocity,

Translational
enables the specification of a translational wall velocity.

Rotational
enables the specification of a rotational wall velocity.

Components
enables the specification of wall velocity components.

Speed
sets the translational or rotational speed of the wall (depending on whether you selected **Translational** or **Rotational**).

Direction
sets the direction vector of the translational velocity. (This item will appear if you have chosen the **Translational** option.)

Rotation-Axis Origin
sets the coordinates of the origin of the axis of rotation, thereby determining the location of the axis. (This item will appear if you have chosen the **Rotational** option for a non-axisymmetric case.)

Rotation-Axis Direction
sets the direction vector for the axis of rotation. (This item will appear if you have chosen the **Rotational** option for a non-axisymmetric case.)

Velocity Components
sets the **X**, **Y**, and **Z-Velocity** components of the wall motion. (This item will appear if you have chosen the **Components** option.)

Shear Condition
contains options for specifying the shear conditions at the wall.

No Slip
specifies a no-slip condition at the wall. No further inputs are required.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specified Shear
enables specification of zero or nonzero shear. See Specified Shear (p. 362) for details. This option is not available for moving walls.

Marangoni Stress
enables the specification of shear stress caused by the variation of surface tension due to temperature. This option is not available for moving walls.

Shear Stress
contains inputs related to wall shear. These items will appear when **Specified Shear** is selected as the **Shear Condition**. See Specified Shear (p. 362) for details.

X-Component, Y-Component, Z-Component, Swirl Component
specify the x, y, and z or swirl components of shear for a slip wall. **Swirl Component** is available only for axisymmetric swirl cases.

Specularity Coefficient
is used in multiphase granular flow. You can specify the specularity coefficient such that when the value is zero, this condition is equivalent to zero shear at the wall, but when the value is near unity, there is a significant amount of lateral momentum transfer.

Specularity Coefficient
allows you to enter a value between zero and one, which controls the amount of lateral momentum transfer.

Marangoni Stress
contains inputs related to Marangoni stress. This item will appear when **Marangoni Stress** is selected as the **Shear Condition**. See Marangoni Stress (p. 363) for details.

Surface Tension Gradient
specifies the surface tension gradient with respect to temperature ($d\sigma / dT$ in Equation 6.103 (p. 363)).

Wall Roughness
contains various models for defining wall roughness size/height in turbulent calculations.

Standard
uses the standard wall roughness methods for most turbulence models. See Wall Roughness Effects in Turbulent Wall-Bounded Flows (p. 364) for details.

High Roughness (Icing)
contains various models for use only with the Spalart-Allmaras and SST k-ω turbulence models. Specifically applicable to icing simulations, choose from **Specified Roughness**, **NASA Correlation**, **Shin-et-al**, or **ICE3D Roughness File** methods to specify the **Sand-Grain Roughness**. See Additional Roughness Models for Icing Simulations (p. 368) for details.

Wall Adhesion
contains inputs related to wall adhesion. This section of the dialog box will appear if you are using the VOF model and have enabled wall adhesion in the e Phase Interaction Dialog Box (p. 2363).

Contact Angles
specifies the contact angle at the wall for each pair of phases (θ_w in Figure 24.31: Measuring the Contact Angle (p. 1442) in the Theory Guide). See Steps for Setting Boundary Conditions (p. 1391) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thermal

contains the thermal parameters. This tab is available only when the energy equation is turned on.

Thermal Conditions

contains radio buttons for selecting the thermal boundary condition type. See Thermal Boundary Conditions at Walls (p. 370) for details about these inputs:

Heat Flux

selects a specified heat flux condition.

Temperature

selects a specified wall temperature condition.

Convection

selects a convective heat transfer boundary condition model.

Radiation

selects an external radiation boundary condition.

Mixed

selects a combined convection/external radiation boundary condition.

Coupled

selects a coupled heat transfer condition. It is applicable only to walls that form the interface between two regions (such as the fluid/solid interface for a conjugate heat transfer problem).

via System Coupling

selects a heat transfer condition where a boundary can receive thermal data (either wall temperature or heat flow) from the System Coupling service. It is applicable when ANSYS Fluent is coupled with another system in Workbench using System Coupling (see Heat Transfer Boundary Conditions Through System Coupling (p. 377) for details).

via Mapped Interface

specifies that the thermal data is interpolated across a mapped interface. It is available only for the interface wall boundary zones created as part of a mapped interface (see Heat Transfer Boundary Conditions Across a Mapped Interface (p. 378) for details).

Once a condition type has been selected, the appropriate conditions can be specified.

Heat Flux

sets the wall heat flux to be used for the **Heat Flux** condition. A specification of zero **Heat Flux** is simply the adiabatic condition (no heat transfer). A positive value of heat flux implies that heat enters *into* the domain.

Temperature

sets the wall temperature to be used for the **Temperature** condition.

Heat Transfer Coefficient

sets the convective heat transfer coefficient to be used for the **Convection** condition (h_{eff} in Equation 6.122 (p. 383)).

Free Stream Temperature

sets the reference or free stream temperature to be used for the **Convection** condition (T_{ext} in Equation 6.122 (p. 383)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

External Emissivity
sets the emissivity of the external wall to be used for the **Radiation** condition (ε_{ext} in Equation 6.123 (p. 383)).

External Radiation Temperature
sets the temperature of the external radiation source/sink to be used for the **Radiation** condition (T_∞ in Equation 6.123 (p. 383)).

Internal Emissivity
sets the internal emissivity of the wall. This item will appear only if you are using the gray P-1, DO, or MC models, the DTRM, or the S2S model for radiation heat transfer. (Note that it will not appear if you are using the non-gray P-1, DO, or MC model. In these cases, you will enter the **Internal Emissivity** for each band in the **Radiation** tab.)

Wall Thickness
sets the thickness of a thin wall for the calculation of thermal resistance. (See Thin-Wall Thermal Resistance Parameters (p. 373) for details.)

Heat Generation Rate
sets the rate of heat generation in a wall without shell conduction.

Contact Resistance
sets the contact resistance (R_c in Equation 18.23 in the Theory Guide) at the wall. See Modeling Solidification and Melting (p. 1527) for details. This item appears only when the solidification/melting model is used.

Material Name
sets the material type for a thin wall. The conductivity of the material is used for the calculation of thin-wall thermal resistance. (See Thin-Wall Thermal Resistance Parameters (p. 373) for details.) **Material** is used only when **Wall Thickness** is nonzero. Materials are defined with the Materials Task Page (p. 2300).

Shell Conduction
enables shell conduction for the wall. See Shell Conduction (p. 376) for details.

Edit...
is only available when **Shell Conduction** is enabled, and opens the Shell Conduction Layers Dialog Box (p. 2804) in order to allow you to define the shell conduction settings for the wall.

Radiation
displays the boundary conditions for the S2S model, the DO model, the MC model, and the non-gray P-1 model at the wall. This tab is only available if you are using the surface to surface model, the discrete ordinates model, the monte carlo model, or the non-gray P-1 model. See Forming Surface Clusters (p. 853), Wall Boundary Conditions for the DO Model (p. 871), and Wall Boundary Conditions for the DTRM, and the P-1, S2S, and Rosseland Models (p. 870) for details.

BC Type
contains a drop-down list of available radiation boundary condition types. The available options are **opaque** and **semi-transparent**. This item will appear only if you are using the discrete ordinates model.

Internal Emissivity
specifies the internal emissivity of the wall in each wavelength band. This item will appear only if you are using the non-gray discrete ordinates model and you have selected **opaque** as the **BC Type**, or if you are using the non-gray P-1 model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Diffuse Fraction

specifies the fraction of the irradiation that is to be treated as diffuse. By default, the **Diffuse Fraction** is set to 1, indicating that all of the irradiation is diffuse. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band. This item will appear only if you are using the Monte Carlo or discrete ordinates model.

Beam Width

specifies the beam width for an external semi-transparent wall in terms of the **Theta** and **Phi** extents. This item will appear only if you are using the discrete ordinates radiation model and you have selected **semi-transparent** as the **BC Type**.

Beam Direction

specifies the beam direction as an **X,Y,Z** vector. You can specify the **Beam Direction** as a constant, a profile, or a user-defined function. This item will appear only if you are using the Monte Carlo model or the discrete ordinates radiation model and you have selected **semi-transparent** as the **BC Type**.

Direct Irradiation

specifies the value of the irradiation flux. If the non-gray DO model is being used, a constant **Direct Irradiation** can be specified for each band.

This item will appear only if you are using the Monte Carlo model or the discrete ordinates radiation model and you have selected **semi-transparent** as the **BC Type**.

Apply Direct Irradiation Parallel to the Beam

is the default means of specifying the scale of irradiation flux. When enabled, ANSYS Fluent assumes that the value of **Direct Irradiation** that you specify is the irradiation flux parallel to the **Beam Direction**. When deselected, ANSYS Fluent instead assumes that the value specified is the flux parallel to the face normals and will calculate the resulting beam parallel flux for every face. This item will appear only if you are using the discrete ordinates model.

Diffuse Irradiation

specifies the value of the irradiation flux. If the non-gray DO model is being used, a constant **Diffuse Irradiation** can be specified for each band.

This item will appear only if you are using the discrete ordinates radiation model and you have selected **semi-transparent** as the **BC Type**.

Solar Boundary Conditions

contains the settings for solar ray tracing. This group box is available only if you select **Solar Ray Tracing** from the **Model** list in the **Solar Load** group box of the **Radiation Model** dialog box. For semitransparent coupled walls, the solar ray tracing settings are defined on the original wall and not on the shadow wall. See Solar Ray Tracing (p. 900) for details.

Participates in Solar Ray Tracing

specifies whether or not the wall participates in solar ray tracing.

Absorptivity

contains the settings that define the absorptivity of wall.

Direct Visible

specifies a multiplier (ranging from 0 to 1) that is applied to the visible portion of the direct solar radiation spectrum to account for the absorption of the wall. The value should be defined for normal incident rays.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Direct IR
specifies a multiplier (ranging from 0 to 1) that is applied to the infrared portion of the direct solar radiation spectrum to account for the absorption of the wall. The value should be defined for normal incident rays.

Diffuse Hemispherical
specifies a multiplier (ranging from 0 to 1) that is applied to the diffuse solar radiation to account for the absorption of the wall. This setting is only available for semi-transparent walls.

Transmissivity
contains the settings that define the transmissivity of wall. This group box is only available when **semi-transparent** is selected for **BC Type**.

Direct Visible
specifies a multiplier (ranging from 0 to 1) that is applied to the visible portion of the direct solar radiation spectrum to account for the transmissivity of the wall. The value should be defined for normal incident rays. This setting is only available for semi-transparent walls.

Direct IR
specifies a multiplier (ranging from 0 to 1) that is applied to the infrared portion of the direct solar radiation spectrum to account for the transmissivity of the wall. The value should be defined for normal incident rays. This setting is only available for semi-transparent walls.

Diffuse Hemispherical
specifies a multiplier (ranging from 0 to 1) that is applied to the diffuse solar irradiation to account for the transmissivity of the wall. This setting is only available for semi-transparent walls.

S2S Parameters
contains the settings for the S2S radiation model. This group box is available only if you select the **Surface to Surface** radiation model. See Forming Surface Clusters (p. 853) for details.

Faces Per Surface Cluster
sets the number of faces per surface cluster (FPSC) for the wall, and thus controls the number of radiating surfaces and (if you select **Cluster to Cluster** for **Basis** in the **View Factors and Clustering** dialog box) view factor surfaces.

Critical Zone
specifies that the wall is a critical zone. When this option is enabled, the value entered for **Faces Per Surface Cluster** will not be altered when you use **Automatic** clustering in the **View Factors and Clustering** dialog box, and impacts the calculations and actions performed by the buttons in the **Maximum Distance from Critical Zone** group box of the **Participating Boundary Zones** dialog box.

Participates in View Factor Calculation
specifies whether or not the wall participates in the view factor calculation as part of the S2S radiation model. This option is available only if you select the **Surface to Surface** radiation model.

Species
contains the species parameters. This tab is available only if you have enabled the **Species Transport** model in the Species Model Dialog Box (p. 2216).

Reaction
activates reactions at the wall. This item will appear only if you have enabled any of the reactions in the Species Model Dialog Box (p. 2216).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reaction Mechanisms
allows you to specify a defined group, or mechanism, of available reactions. This item will appear only if the **Reaction** option has been turned on. See Defining Zone-Based Reaction Mechanisms (p. 984) for details about defining reaction mechanisms.

Surface Area Washcoat Factor
allows you to specify a factor, which multiplies the wall area to account for the increased surface area of washcoats. This item will appear only if the **Reaction** option has been turned on. See Species Boundary Conditions for Walls (p. 379) for details.

Species Boundary Condition
contains options for the specification of species boundary conditions. See Species Boundary Conditions for Walls (p. 379) for details.

Zero Diffusive Flux
indicates a zero-flux condition for a species. This is the default condition.

Specified Mass Fraction
indicates that the species mass fraction will be specified.

Species Mass Fractions
contains inputs for the species mass fractions of any species for which you have selected **Species Mass Fraction** as the **Species Boundary Condition**.

DPM
contains the discrete phase parameters. This tab is available only if you have defined at least one injection.

Discrete Phase Model Conditions
contains inputs for setting the fate of particle trajectories at the wall. These options will appear when one or more injections have been defined. See Setting Boundary Conditions for the Discrete Phase (p. 1301) for details.

Boundary Cond. Type
sets the way that the discrete phase behaves with respect to the boundary.

reflect
rebounds the particle off the boundary with a change in its momentum as defined by the coefficients of restitution (see Particle Reflection at Wall in the *Fluent Theory Guide*). When at least one injection accounts for the rough wall model (the **Rough Wall Model** option is selected under the **Physical Models** tab in the **Set Injections Properties** dialog box), you can specify the **DPM Wall Roughness Parameters** (**Ra**, **Rq**, and **RSm** in Equation 16.216 in the *Fluent Theory Guide*). (See Rough Wall Model (p. 1292)).

trap
terminates the trajectory calculations and records the fate of the particle as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303).

escape
reports the particle as having "escaped" when it encounters the boundary. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

wall-jet
indicates that the direction and velocity of the droplet particles are given by the resulting momentum flux, which is a function of the impingement angle. See Figure 16.6:"Wall Jet" Boundary Condition for the Discrete Phase in the Theory Guide.

wall-film
allows you to enable **Film Condensation** (Film Condensation Model (p. 1307)), **Wall Boundary Layer Model** (Wall Boundary Layer Model (p. 1309)), and specify the **Film Model Parameters**:

Number Of Splashed Drops
is used to model splashing. The minimum number of splashed parcels is three. A value of zero implies no splashing.

Critical Temperature Factor
is used to determine the transition temperature (Equation 16.222 and Equation 16.250 in the *Fluent Theory Guide* for the **stanton-rutland** and **kuhnke** splashing models, respectively).

Impingement/Splashing Model

stanton-rutland
(default) consists of four regimes, namely, stick, rebound, spread, and splash, which are based on the impact energy and wall temperature. See The Stanton-Rutland Model in the *Fluent Theory Guide* for more details.

kuhnke
consists of four regimes: spread, rebound, splash, and dry splash (thermal breakup). See The Kuhnke Model in the *Fluent Theory Guide* for more details. You must specify the following **DPM Wall Roughness Parameters**:

Roughness Ra
is used to compute K_{cold} in Equation 16.258 in the *Fluent Theory Guide*.

Roughness Rz
Roughness Rz: is used to compute splashed droplets ejection angle in Equation 16.270 in the *Fluent Theory Guide*.

user-defined
specifies a user-defined function to define the discrete phase boundary condition type.

Boundary Cond. Function
sets the user-defined function from the drop-down list.

Discrete Phase Reflection Coefficients
determine the behavior of reflecting particles. This item appears when **reflect** is chosen as the **Boundary Cond. Type**. See Discrete Phase Boundary Condition Types (p. 1301) for details on setting the following items.

Normal
sets the type of function for the normal coefficient of restitution. This function can be **constant**, **piecewise-linear**, **piecewise-polynomial**, or **polynomial**.

Tangent
sets the type of function for the tangential coefficient of restitution. This function can be **constant**, **piecewise-linear**, **piecewise-polynomial**, or **polynomial**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DEM Collision Partner
contains a list of names to designate the collision partner.

Erosion Model
contains a list of erosion models. See Setting Particle Erosion and Accretion Parameters (p. 1309) for details about these items.

Generic Model
specifies erosion rates to be computed using the generic erosion model. (See Accretion in the *Fluent Theory Guide* for background information about this model.) When this model is enabled, you must specify the erosion parameters in the **Generic Erosion Model Parameters** dialog box that opens by clicking the corresponding **Edit...** button as described in Setting Particle Erosion and Accretion Parameters (p. 1309).

Finnie
specifies erosion rates to be computed using the Finnie formulation. (See Accretion in the *Fluent Theory Guide* for background information about this model.) When this model is enabled, you must specify the erosion parameters in the **Finnie Model Parameters** dialog box that opens by clicking the corresponding **Edit...** button as described in Setting Particle Erosion and Accretion Parameters (p. 1309).

McLaury
specifies erosion rates to be computed using the McLaury formulation. (See McLaury Erosion Model in the *Fluent Theory Guide* for background information about this model.) When this model is enabled, you must specify the erosion parameters in the **McLaury Model Parameters** dialog box that opens by clicking the corresponding **Edit...** button as described in Setting Particle Erosion and Accretion Parameters (p. 1309).

Oka
specifies erosion rates to be computed using the Oka formulation. (See Oka Erosion Model in the *Fluent Theory Guide* for background information about this model.) When this model is enabled, you must specify the erosion parameters in the **Oka Model Parameters** dialog box that opens by clicking the corresponding **Edit...** button as described in Setting Particle Erosion and Accretion Parameters (p. 1309).

Friction Coefficient
specifies μ in Equation 16.209 and Equation 16.214 in the *Fluent Theory Guide* as a **constant** or a **piecewise-linear**, **piecewise-polynomial**, or **polynomial** function of relative velocity. This item appears only when **Enable Rotation** is selected under the **Physical Model** tab of the Set Injection Properties Dialog Box (p. 2796).

UDS
displays the boundary conditions for user-defined scalars (UDSs) at the wall. This tab is available only if you have specified a nonzero number of user-defined scalars in the User-Defined Scalars Dialog Box (p. 2829).

User Defined Scalar Boundary Condition
contains options for the specification of UDS boundary conditions. See the separate Fluent Customization Manual for details.

Specified Flux
indicates that the flux of the UDS at the wall will be specified.

Specified Value
indicates that the value for the UDS at the wall will be specified.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Defined Scalar Boundary Value
contains inputs for the value of the flux of the UDS, or the value of the UDS itself, depending on your selection for that UDS under **User Defined Scalar Boundary Condition**.

Wall Film
displays the boundary conditions for liquid films at the wall. This tab is available only if you have enabled the Eulerian Wall Film model in the Models Task Page (p. 2169).

Eulerian Film Wall
allows you to define a film wall condition for any wall. See Modeling Eulerian Wall Films (p. 1535) for details. Once this option is enabled, you can set the following:

Film Condition Type
allows you to select the desired condition type.

Boundary Condition
allows you to specify settings for boundary **Film Conditions**:

Film Mass Flux
The film mass source in terms of mass flux per unit area ($kg/m^2–s$).

X-Momentum Flux, Y-Momentum Flux, and Z-Momentum Flux
The film momentum source in terms of momentum flux per unit area (N/m^2).

Incoming Film Temperature
The film temperature (K).

Film Passive Scalar Flux
The film passive scalar source in terms of mass flux per unit area ($kg/m^2–s$).

Initial Condition
allows you to specify settings for initial **Film Conditions**:

Film Height
The film height at the wall boundary.

X-Velocity, Y-Velocity, and Z-Velocity
The film velocity components at the wall boundary.

Film Temperature
The film temperature (K).

Film Passive Scalar
The film passive scalar at the wall boundary (dimensionless).

Relative Film Momentum Flux
(moving reference frames or moving walls only) enables specification of the film momentum flux relative to the wall on which liquid film is defined (**Boundary Condition** type only). This option is only available when **Moving Wall** is selected in the **Wall** dialog box and/or **Frame Motion** is selected in the **Fluid** dialog box.

Relative Initial Film Velocity
(moving reference frames or moving walls only) enables specification of the initial velocity relative to the wall on which liquid film is defined (**Initial Condition** type only). This option is only available

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

when **Moving Wall** is selected in the **Wall** dialog box and/or **Frame Motion** is selected in the **Fluid** dialog box.

User Source Terms

enables you to specify the additional source terms to the film continuity (**Mass Flux**), momentum (**X-Momentum Flux**, **Y-Momentum Flux**, and **Z-Momentum Flux**), energy (**Heat Flux**), and passive scalar equations (**Scalar Flux**). This option is only available with initial conditions.

Flow Momentum Coupling

When this option is selected, the liquid film and the gas flow will share the same velocity at the interface of the liquid-gas interface using a two-way coupling. When this option is not selected, the coupling between the liquid film and the gas flow is only one-way, namely, while the gas flow impacts the film flow, the film flow does not impact the bulk of the gas flow.

Film Phase Change

enables the phase change for the selected wall. This option is available only when **Phase Change** is selected in the **Model Options and Setup** tab of the Eulerian Wall Film Dialog Box (p. 2294). Once enabled, you can specify the following **Phase Change Parameters** (see Coupling of Wall Film with Mixture Species Transport in the Theory Guide):

Condensation Rate Constant

is the value of C_{con} used in Equation 19.28 in the Theory Guide. You can also specify the condensation rate via a user-defined profile UDF by selecting the name of the compiled UDF from the drop-down list.

Vaporization Rate Constant

is the value of C_{vap} used in Equation 19.28 in the Theory Guide. You can also specify the vaporization rate via a user-defined profile UDF by selecting the name of the compiled UDF from the drop-down list.

Impingement Parameters

contains parameters related to particle-wall impingement

Impingement Model

is a drop-down list that contains available impingement models:

- **stanton-rutland** (default): consists of four impingement regimes: stick, rebound, spread and splash, which are based on the impact energy and wall temperature. See The Stanton-Rutland Model in the *Fluent Theory Guide* for details.
- **kuhnke**: consists of four impingement regimes: stick, rebound, spread and splash (thermal breakup). See The Kuhnke Model in the *Fluent Theory Guide* for details.

DPM Wall Splash

allows you to enable the wall splashing for the selected wall and specify the **Number of Splashed Particles**. The minimum value is 3. This option is available when **Particle Splashing** is enabled in the **Eulerian Wall Film** dialog box.

Kuhnke Model Parameters

(available when the **kuhnke** model is selected from the **Impingement Model** drop-down list)

Wall Roughness Length

enables you to specify wall roughness values used by the Kuhnke model:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Ra**: the wall mean roughness that is used to compute K_{cold} in Equation 16.258 in the *Fluent Theory Guide*
- **Rz**: the average surface roughness that is used to compute splashed particle reflection angle distribution Equation 16.270 in the *Fluent Theory Guide*.

Critical Temperature Factor
is the dimensionless variable that is used to determine the impingement regime transition temperature in Equation 16.250 in the *Fluent Theory Guide*.

Potential
displays the boundary conditions for the electric potential field at the wall. This tab is available only if you have enabled either the **Electric Potential model** under the **Model** tree branch or the **Electrochemical** Reaction model in the Species Dialog Box (p. 2332).

Electrochemical Reaction
enables electrochemical reactions at the wall.

Faradaic Heat
(if enabled) includes heat from the electrochemical reaction in the energy equation.

Potential Boundary Condition
contains a drop-down list of available potential boundary condition types for the external wall: **Specified Flux** and **Specified Value**. For the **Specified Flux** boundary condition, you will need to specify **Current Density** at the wall. For the **Specified Value** boundary condition, you will need to specify **Potential** at the wall.

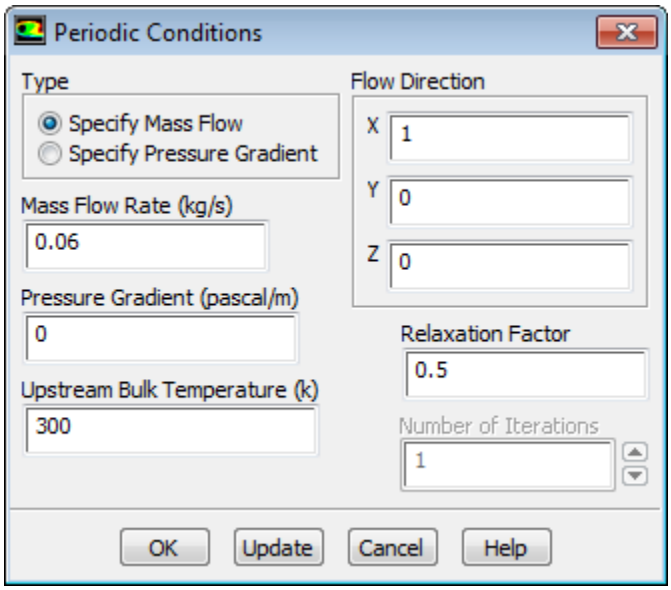
Reaction Mechanism
contains a drop-down list of all available electrochemical reaction mechanisms.

37.8.23. Periodic Conditions Dialog Box

The **Periodic Conditions** dialog box allows you to set parameters that define fully-developed periodic flow and heat transfer. See User Inputs for the Pressure-Based Solver (p. 584) and Using Periodic Heat Transfer (p. 914) for details.

(This dialog box is available only when the pressure-based solver is used; it is not available for the density-based coupled solvers.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Specify Mass Flow
enables the specification of the mass flow rate.

Specify Pressure Gradient
enables the specification of the pressure gradient.

Mass Flow Rate
specifies the mass flow rate. This item will not be available if you selected the **Specify Pressure Gradient** option.

Important

For axisymmetric problems, the mass flow rate is per 2π radians.

Pressure Gradient
specifies the pressure gradient (β in Equation 1.22 in the Theory Guide).

Upstream Bulk Temperature
sets the inlet bulk temperature for periodic heat transfer calculations.

Flow Direction
sets the direction of the periodic flow. The direction vector must be parallel to the periodic translation direction or its opposite.

Relaxation Factor
sets the under-relaxation factor that controls convergence of the iteration process described in Setting Parameters for the Calculation of β (p. 585) for specified mass flow.

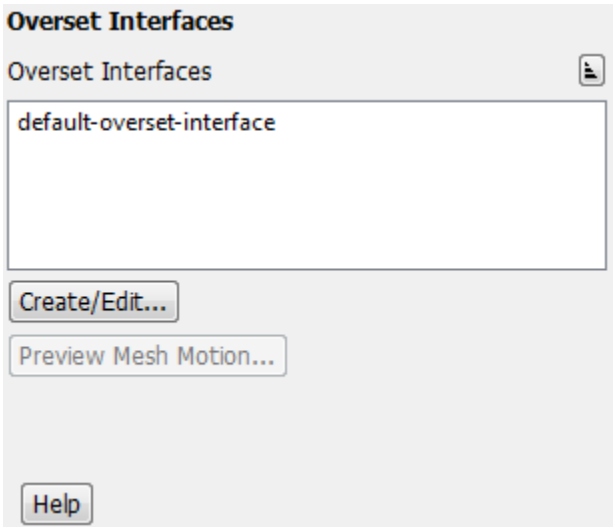
Number of Iterations
sets the number of subiterations done on the correction of β in the pressure correction equation for specified mass flow. See Setting Parameters for the Calculation of β (p. 585) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Update
updates the **Pressure Gradient** field with the current value.

37.9. Overset Interfaces Task Page

The **Overset Interfaces** task page allows you to create overset interfaces. For additional information about overset interfaces, see Overset Meshes (p. 172).



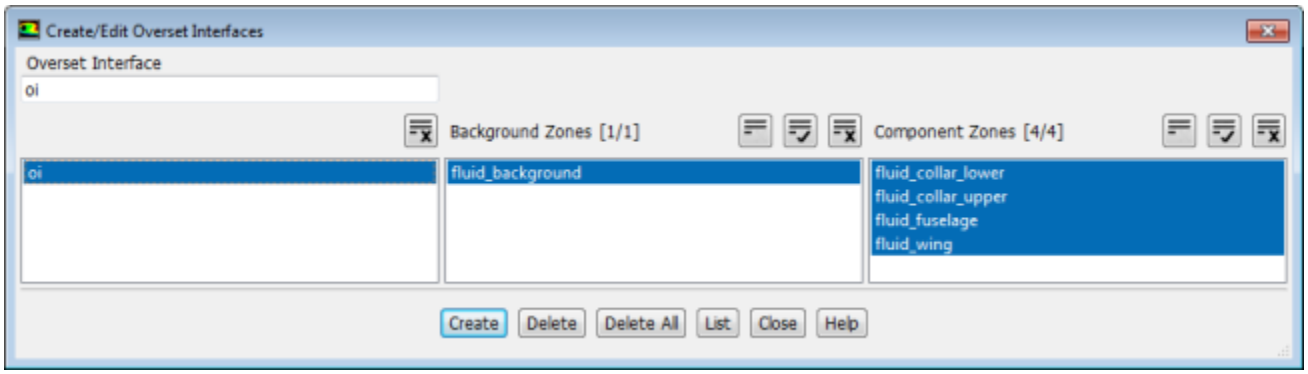
Controls

Create/Edit...
displays the Create/Edit Overset Interfaces Dialog Box (p. 2470).

Preview Mesh Motion...
displays the Mesh Motion Dialog Box (p. 2500).

37.9.1. Create/Edit Overset Interfaces Dialog Box

The **Create/Edit Overset Interfaces** dialog box allows you to create and delete overset interfaces. For additional information, see Overset Meshes (p. 172).



Overset Interface
contains a text entry box where you must specify the name of the overset interface. Below is a list of all existing overset interfaces.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Background Zones
lists all of the background zones available for selection when creating an overset interface. Multiple background zones can be part of an overset interface, however a background zone cannot be part of multiple overset interfaces.

Component Zones
lists all of the component zones available for selection when creating of an overset interface. Multiple components can be part of an overset interface, however a component zone cannot be part of multiple overset interfaces.

Create
creates an overset interface using the name in the **Overset Interface** text box and the zones selected under **Background Zones** and **Component Zones**. Note that grid priorities, if required, are added to the interface after it is created, using the text command `define/overset-interfaces/grid-priorities`.

Delete
deletes the selected **Overset Interface**.

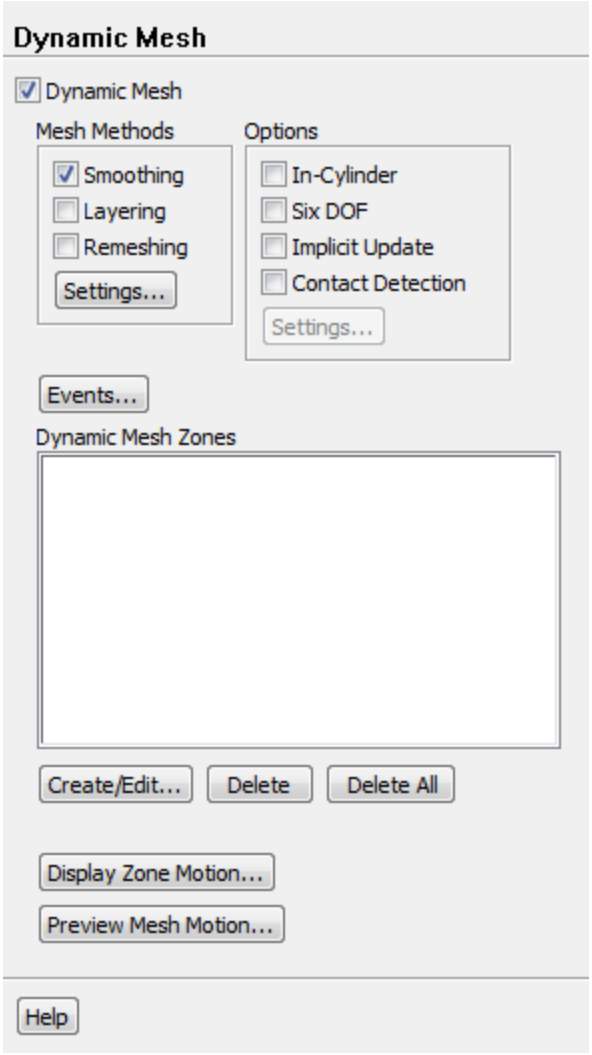
Delete All
deletes all overset interfaces in the domain.

List
prints zonal information and grid priorities for the selected **Overset Interface**.

37.10. Dynamic Mesh Task Page

The **Dynamic Mesh** task page allows you to define the all the parameters for modeling a dynamic mesh model. See Setting Dynamic Mesh Modeling Parameters (p. 643) for details about using the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Dynamic Mesh
enables the dynamic mesh model and activates the controls in the task page.

Mesh Methods
contains options to specify the mesh update method(s).

Smoothing
enables mesh smoothing. See Smoothing Methods (p. 644) for details about the smoothing methods available.

Layering
enables the dynamic layering method that can be used to add or remove layers of cells adjacent to a moving boundary based on the height of the layer adjacent to the moving surface in prismatic mesh zones. See Dynamic Layering (p. 661) for details.

Remeshing
enables the local or zonal remeshing methods. In local remeshing, the cells that violate the skewness or size criteria are agglomerated and locally remeshed; see Local Remeshing Method (p. 668) for further details. In zonal remeshing, the complete cell zone (including the boundary zones) is remeshed; see CutCell Zone Remeshing Method (p. 681) for further details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Settings...
displays the Mesh Method Settings Dialog Box (p. 2474) in which you can specify settings for the Smoothing, Layering, and Remeshing methods.

Options
contains options to specify specialized dynamic mesh models.

In-Cylinder
enables the in-cylinder model. See In-Cylinder Settings (p. 690) for more information.

Six DOF
enables the six degrees of freedom (DOF) solver. See Six DOF Solver Settings (p. 705) for more information.

Implicit Update
specifies that the mesh is updated during a time step (as opposed to just at the beginning of a time step). See Implicit Update Settings (p. 709) for more information.

Contact Detection
enables contact detection. See Contact Detection Settings (p. 711) for more information.

Settings...
opens the Options Dialog Box (p. 2478), where you can set the parameters for the options that are enabled in the **Options** group box.

Events...
displays the Dynamic Mesh Events Dialog Box (p. 2486).

Dynamic Mesh Zones
displays a list of dynamic mesh zones.

Create/Edit...
displays the Dynamic Mesh Zones Dialog Box (p. 2490).

Delete
removes the selected dynamic zone(s) from the **Dynamic Mesh Zones** list.

Delete All
removes all dynamic zones from the **Dynamic Mesh Zones** list.

Display Zone Motion...
displays the Zone Motion Dialog Box (p. 2499).

Preview Mesh Motion...
displays the Mesh Motion Dialog Box (p. 2500).

37.10.1. Mesh Method Settings Dialog Box

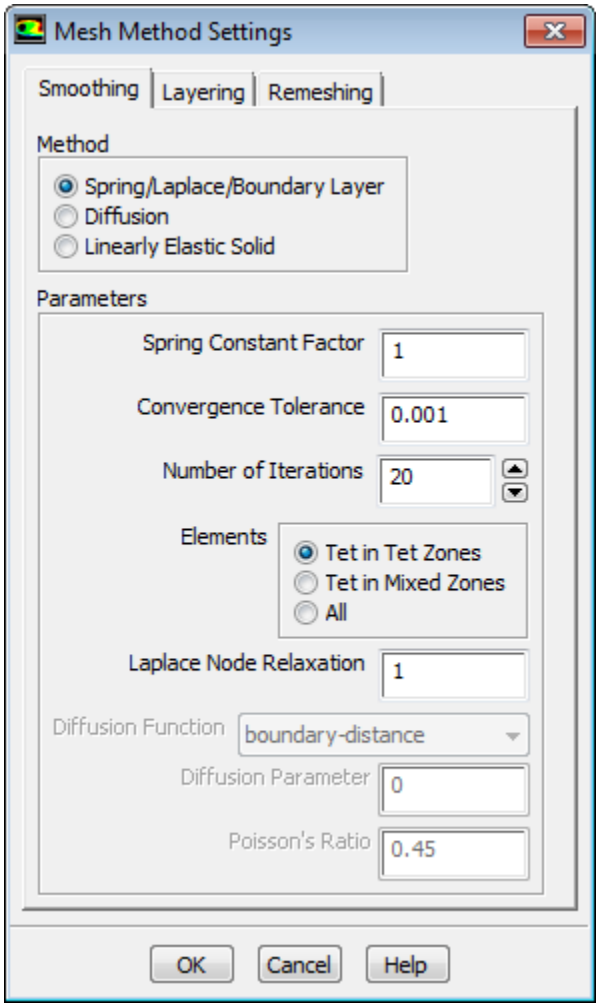
The **Mesh Method Settings** dialog box allows you to apply settings for the smoothing, layering, or remeshing methods.



Smoothing

contains parameters to be specified for the smoothing mesh update method.

Method

allows you to specify the smoothing method.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Spring/Laplace/Boundary Layer
specifies that the smoothing method is spring based, or appropriate for the Laplacian smoothing method (for 2.5D remeshing) or the boundary layer smoothing method.

Diffusion
selects the diffusion-based smoothing method.

Linearly Elastic Solid
selects smoothing based on the equations for a linearly elastic solid.

Parameters
allows you to define the settings for the smoothing.

Spring Constant Factor
controls the spring stiffness.

Convergence Tolerance
controls the smoothing convergence.

Number of Iterations
specifies the number of iterations.

Elements
controls the elements where spring-based smoothing is applied.

Tet in Tet Zones
(3D only) only cell zones with all tetrahedral elements get smoothed.

Tet in Mixed Zones
(3D only) tetrahedral elements in mixed element zones get smoothed.

Tri in Tri Zones
(2D only) only cell zones with all triangular elements get smoothed.

Tri in MixedZones
(2D only) triangular elements in mixed element zones get smoothed.

All
all element types get smoothed.

Laplace Node Relaxation
specifies how the update of the node positions is relaxed on boundaries where there is Laplacian smoothing.

Diffusion Function
specifies whether the diffusion coefficient is a function of the **boundary-distance** (Equation 10.8 (p. 650)) or the **cell-volume** (Equation 10.9 (p. 650)). This drop-down list is only available when **Diffusion** is selected from the **Method** list.

Diffusion Parameter
specifies α in Equation 10.8 (p. 650) or Equation 10.9 (p. 650), depending on the selected **Diffusion Function**. This number-entry box is only available when **Diffusion** is selected from the **Method** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Poisson's Ratio
specifies the linearly elastic solid material property ν in Equation 10.12 (p. 656).

Layering
contains parameters to be specified for the layering mesh update method.

Options
specifies the criteria for splitting or collapsing cell layers.

Height Based
specifies that the cell layers are split or merged based on height.

Ratio Based
specifies that the cell layers are split or merged based on ratios.

Split Factor
specifies the value of α_s in Equation 10.15 (p. 662). It controls the height or ratio at which the cells are split.

Collapse Factor
specifies the value of α_c in Equation 10.16 (p. 663). It controls the height or ratio at which the cells are collapsed and merged into the next layer.

Remeshing
contains parameters to be specified for the remeshing mesh update method.

Remeshing Methods
contain options that control remeshing.

Local Cell
allows you to remesh deforming boundary cells.

Local Face
allows you to remesh deforming boundary faces. This option is available for 3D cases.

Region Face
allows you to remesh a region.

CutCell Zone
allows you to replace an entire cell zone with a predominantly Cartesian mesh. This option is only available for 3D cases. Note that the parameters that control this remeshing method are set in the **Dynamic Mesh Zones** dialog box. See Using the CutCell Zone Remeshing Method (p. 683) for more information.

2.5D
enables the 2.5D model. This option is only available for 3D cases. See Using the 2.5D Model (p. 686) for more information.

Parameters
contains parameters that control remeshing for all of the remeshing methods except for **CutCell Zone**.

Minimum Length Scale
specifies the lower limit of cell size below which the cells are marked for remeshing.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum Length Scale
specifies the upper limit of cell size above which the cells are marked for remeshing.

Maximum Cell Skewness
specifies the desired maximum skewness for the mesh.

Maximum Face Skewness
specifies the desired maximum skewness for the surface mesh. This option is active, when **Local Face** is selected under **Remeshing Methods**.

Size Remeshing Interval
specifies the interval in time steps for remeshing based on the above size criteria only. Marking of cells based on skewness occurs automatically at every time step when **Remeshing** is enabled.

Mesh Scale Info...
opens the Mesh Scale Info Dialog Box (p. 2477), in which you can view the statistics of the mesh, such as the minimum and maximum length scale values and the maximum cell and face skewness values.

Use Defaults
resets the remeshing parameters to the default values.

Sizing Function
contains parameters that control the sizing function.

On
allows you to enable or disable the sizing function.

Resolution
sets the resolution for the sizing function. See Setting Dynamic Mesh Modeling Parameters (p. 643) for more information. This item will appear only if **Sizing Function** is enabled.

Variation
specifies the value of α in Equation 10.22 (p. 674). This item will appear only if **Sizing Function** is enabled.

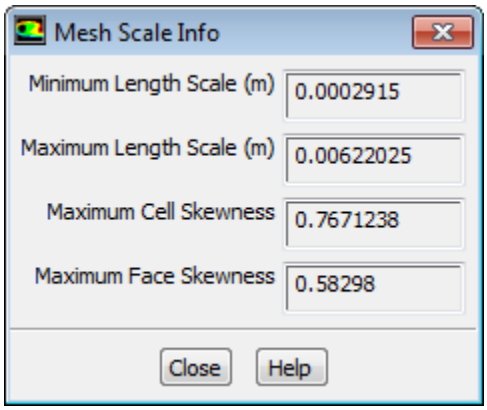
Rate
specifies the value of β in Equation 10.23 (p. 674). This item will appear only if **Sizing Function** is enabled.

Use Defaults
resets the sizing function parameters to the default values. This item will appear only if **Sizing Function** is enabled.

37.10.2. Mesh Scale Info Dialog Box

The **Mesh Scale Info** dialog box allows you to inspect the values of minimum and maximum length scale and maximum cell/face skewness in a mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Minimum Length Scale
displays the lower limit of cell size below which the cells are marked for remeshing.

Maximum Length Scale
displays the upper limit of cell size below which the cells are marked for remeshing.

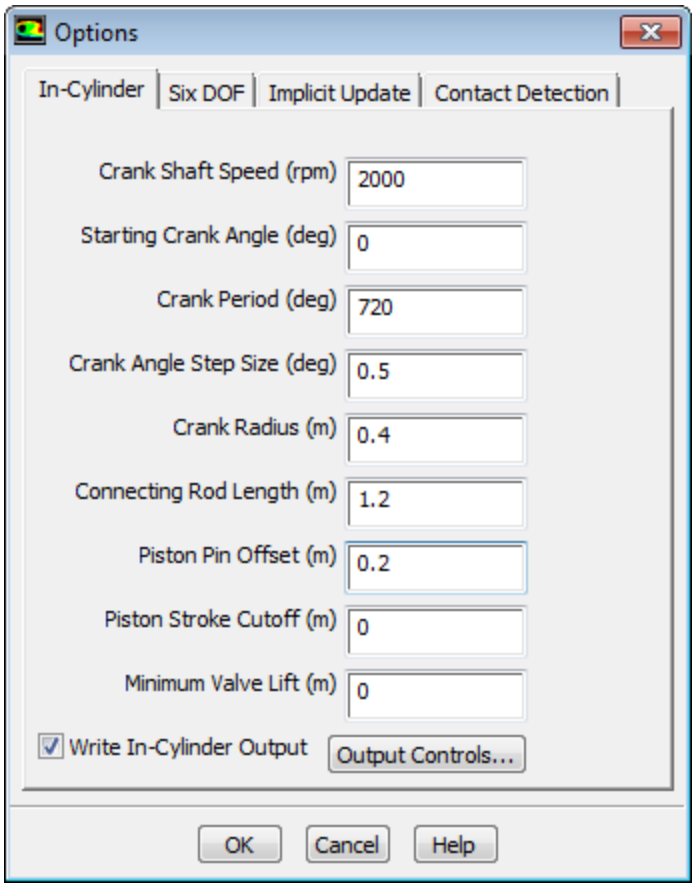
Maximum Cell Skewness
displays the maximum cell skewness in the zone.

Maximum Face Skewness
displays the maximum cell skewness in the surface mesh.

37.10.3. Options Dialog Box

The **Options** dialog box allows you to set the parameters for the options available in the **Options** group box of the **Dynamic Mesh** task page.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In-Cylinder

contains parameters to be specified for the in-cylinder model. See In-Cylinder Settings (p. 690) for more information.

Crank Shaft Speed

specifies the speed of the crank shaft.

Starting Crank Angle

specifies the starting crank angle.

Crank Period

specifies the crank period.

Crank Angle Step Size

specifies the crank angle step size used to determine the time step size to advance the solution.

Crank Radius

specifies the crank radius to calculate the piston location.

Piston Pin Offset

specifies the perpendicular offset of the piston pin from the plane defined by the crank shaft axis and the direction of motion of the piston. The sign of this value is positive if top-dead-center (TDC) occurs prior to a crank angle of 0°.

Connecting Rod Length

specifies the length of the connecting rod.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Piston Stroke Cutoff
specifies the piston stroke cutoff used to control the onset of layering in the cylinder chamber.

Minimum Valve Lift
specifies the minimum valve lift.

Write In-Cylinder Output
enables or disables the writing of in-cylinder specific output parameters. When this option is enabled, the **Output Controls...** button becomes active.

Output Controls...
displays the In-Cylinder Output Controls Dialog Box (p. 2481) and is available only after the **Write In-Cylinder Output** option is enabled.

Six DOF
contains parameters to be specified for the six degrees of freedom (DOF) solver. See Six DOF Solver Settings (p. 705) for more information.

Six DOF Properties
displays a list of defined sets of six DOF properties.

Create/Edit...
opens the Six DOF Properties Dialog Box (p. 2482).

Delete
removes the selected set of six DOF properties from the **Six DOF Properties** list.

Delete All
removes all sets of six DOF properties from the **Six DOF Properties** list.

Gravitational Acceleration
contains the text entry boxes for gravitational acceleration in X, Y, and Z directions.

X, Y, Z
specifies the gravitational acceleration in X, Y, and Z directions respectively.

Write Motion History
allows you to keep track of an object's motion history.

File Name
allows you to specify a file name for saving the object's motion history.

Implicit Update
contains parameters to be specified for implicit mesh updating. See Implicit Update Settings (p. 709) for more information.

Update Interval
allows you to specify the frequency in iterations at which the mesh will be updated within a time step.

Motion Relaxation
allows you to set a value (within the range of 0 to 1) for ω in Equation 10.29 (p. 711), which defines the relaxation of the motion (that is, displacement of the nodes) during the mesh update.

Residual Criteria
allows you to set the relative residual threshold that is used to check the motion convergence.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Contact Detection
contains parameters to be specified for contact detection. See Contact Detection Settings (p. 711) for more information.

Face Zones
allows you to select the face zones that will be involved in contact detection.

Proximity Threshold
allows you to set the threshold below which the user-defined function for contact detection will be invoked.

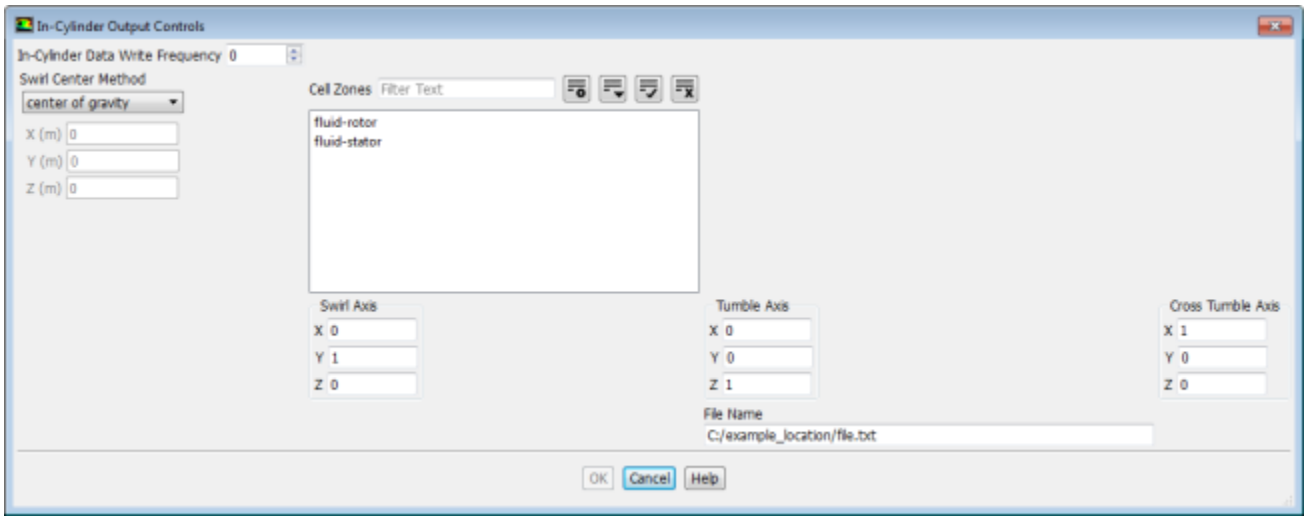
UDF
allows you to specify the user-defined function that will be invoked when contact has been detected.

Flow Control
allows you to indicate whether flow control zones are going to be used in the contact detection process.

Controls...
opens the Flow Controls Dialog Box (p. 2485) where you can make additional flow control settings.

37.10.4. In-Cylinder Output Controls Dialog Box

The **In-Cylinder Output Controls** dialog box contains parameters that control the output for the in-cylinder model. See In-Cylinder Settings (p. 690) for more information.



Controls

In-Cylinder Data Write Frequency
represents an integer entry specifying the interval in number of time-steps. Make sure that a value other than 0 is used for the frequency, in order to allow you to complete your setup.

Swirl Center Method
contains a drop-down list that allows you to select the method to calculate the swirl center. The list contains **center of gravity** and **fixed**, with **center of gravity** being the default value.

center of gravity
calculates the swirl center inside the code and is used as the center of gravity of the chosen cell zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fixed
enables you to specify a swirl center in the **X**, **Y**, and **Z** entry fields below the drop-down list.

In addition to these two options, you can chose to use your own **Compiled** user-defined function to calculate the swirl center. For details on using a dynamic mesh UDF, see the separate Fluent Customization Manual.

Cell Zones
is a list that displays the names of all existing cell zones in the case files. You can select only the zones relevant for the swirl and tumble calculations.

Swirl Axis
specifies the swirl axis with three entries for the directional components. By default, **X**, **Y**, **Z**= **0**, **1**, **0**.

Tumble Axis
specifies the directional components of **Tumble Axis** in **X**, **Y**, **Z** directions. By default, **X**, **Y**, **Z** = **0**, **0**, **1**. This applies only in 3D.

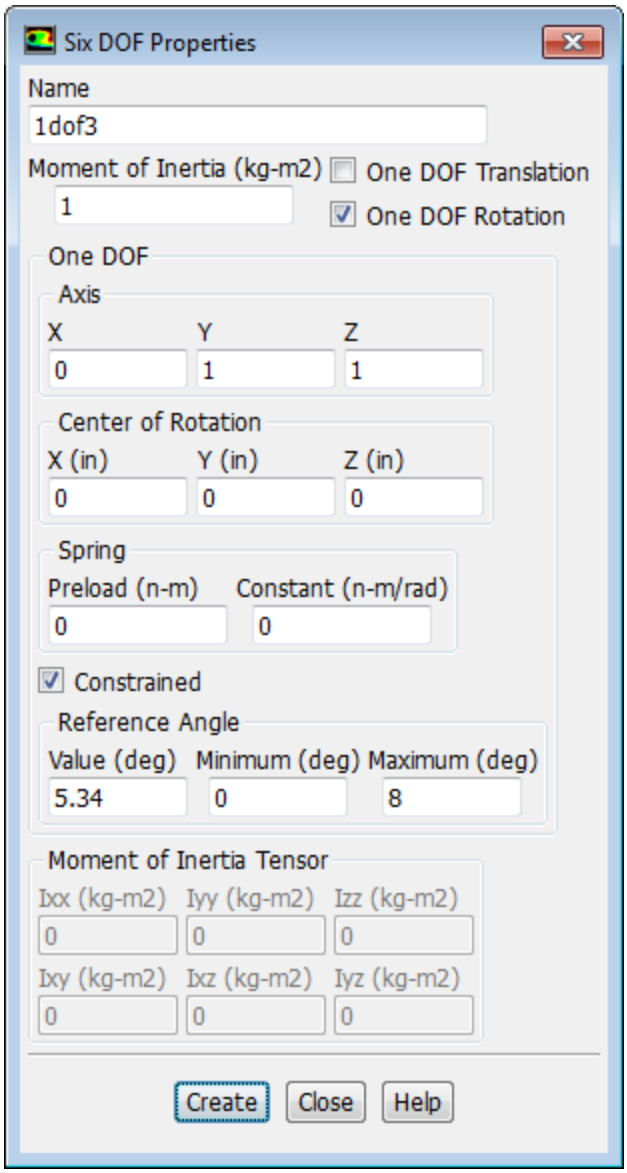
Cross Tumble Axis
specifies the directional components of **Cross Tumble Axis** in **X**, **Y**, **Z** directions. By default, **X**, **Y**, **Z** = **1**, **0**, **0**. This applies only in 3D.

File Name
specifies the name of the **In-Cylinder** output file. By default, the file name contains the name of the case file appended with a `.txt` extension.

37.10.5. Six DOF Properties Dialog Box

The **Six DOF Properties** dialog box allows you to define a set of properties for a rigid body dynamic object that uses the **Six DOF** solver. The set of properties that you create can then be selected in the **Six DOF UDF/Properties** drop-down in the Dynamic Mesh Zones Dialog Box (p. 2490) for the zones that make up the object. See Setting Rigid Body Motion Attributes for the Six DOF Solver (p. 707) and Rigid Body Motion (p. 726) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name

specifies the name of the set of properties, which will be selectable in the **Six DOF UDF/Properties** drop-down in the Dynamic Mesh Zones Dialog Box (p. 2490).

Mass

defines the mass of the rigid body dynamic object that undergoes six degrees of freedom (DOF) motion or one DOF translation.

Moment of Inertia

defines the moment of inertia for the rigid body dynamic object that undergoes one degree of freedom (DOF) rotation.

One DOF Translation

specifies that the dynamic object will only undergo one DOF translation.

One DOF Rotation

specifies that the dynamic object will only undergo one DOF rotation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

One DOF
contains settings that define the one DOF translation or rotation.

Direction
defines the vector along which the object will be allowed to translate.

Axis
defines the components of the axis of rotation. Note that for 2D cases, the axis will be either the positive or negative *z* direction, depending on the sign of the value you enter for **Z**.

Center of Rotation
defines the point about which the object rotates.

Spring
contains settings that define an optional Hooke's law spring that can exert forces / torques on the object. It is a compression / extension spring for translations, and it is a torsion spring for rotations.

Preload
defines a spring load that is constantly applied to the object, in addition to the loading resulting from the spring **Constant**. The **Preload** can be a positive or negative value, and is defined relative to the **Direction** (for translation) or the **Axis** (for rotation).

Constant
defines the spring constant / rate.

Constrained
specifies that the range of motion of the object is limited, as defined by the settings in the **Reference Point** group box (for translation) or the **Reference Angle** group box (for rotation).

Reference Point
contains settings that define the limits of the object's translation when the **Constrained** option is enabled.

Location
assigns a coordinate value to a point located on the object in its initial position; the **Minimum** and **Maximum** coordinates are then defined relative to this value along the **Direction** vector, in order to establish the limits of translation.

Minimum
defines the lower extent of the constrained translation along the **Direction** vector, relative to the **Location**.

Maximum
defines the upper extent of the constrained translation along the **Direction** vector, relative to the **Location**.

Reference Angle
contains settings that define the limits of the object's rotation when the **Constrained** option is enabled.

Value
assigns an angular coordinate value to the orientation of the object in its initial position; the **Minimum** and **Maximum** angles are then defined relative to this orientation about the axis of rotation, in order to establish the limits of rotation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

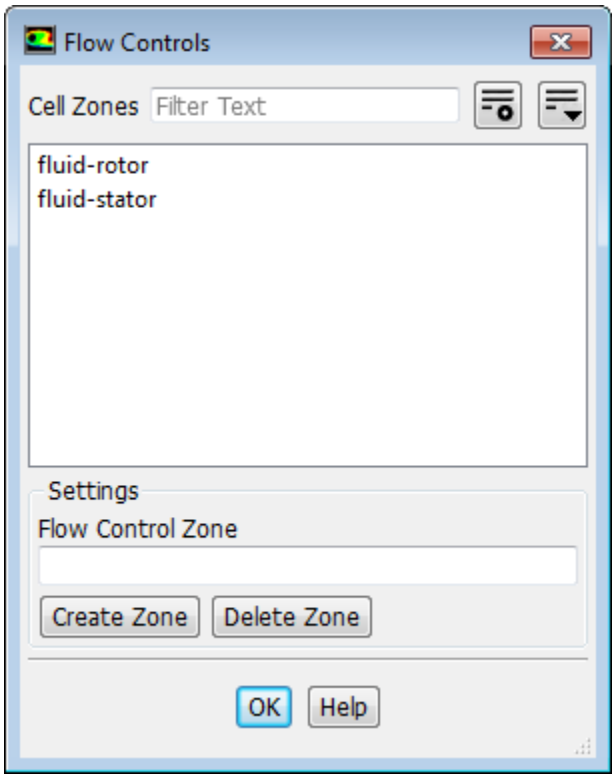
Minimum
defines the lower extent of the constrained rotation about the axis of rotation, relative to the **Value**.

Maximum
defines the upper extent of the constrained rotation about the axis of rotation, relative to the **Value**.

Moment of Inertia Tensor
defines the components of the inertia tensor for the object during six DOF motion. Note that the values are relative to the **Center of Gravity** and **Rigid Body Orientation** settings defined in the Dynamic Mesh Zones Dialog Box (p. 2490); the latter settings allow you to use a coordinate system that is local (rather than global), if that is more convenient.

37.10.6. Flow Controls Dialog Box

The **Flow Controls** dialog box allows you to specify flow control cell zones that are going to be used in the contact detection process. See Contact Detection Settings (p. 711) for more information.



Controls

Cell Zones
is a list that displays the names of all existing cell zones.

Settings
contains flow control zone settings.

Flow Control Zone
allows you to specify a name for the flow control zone.

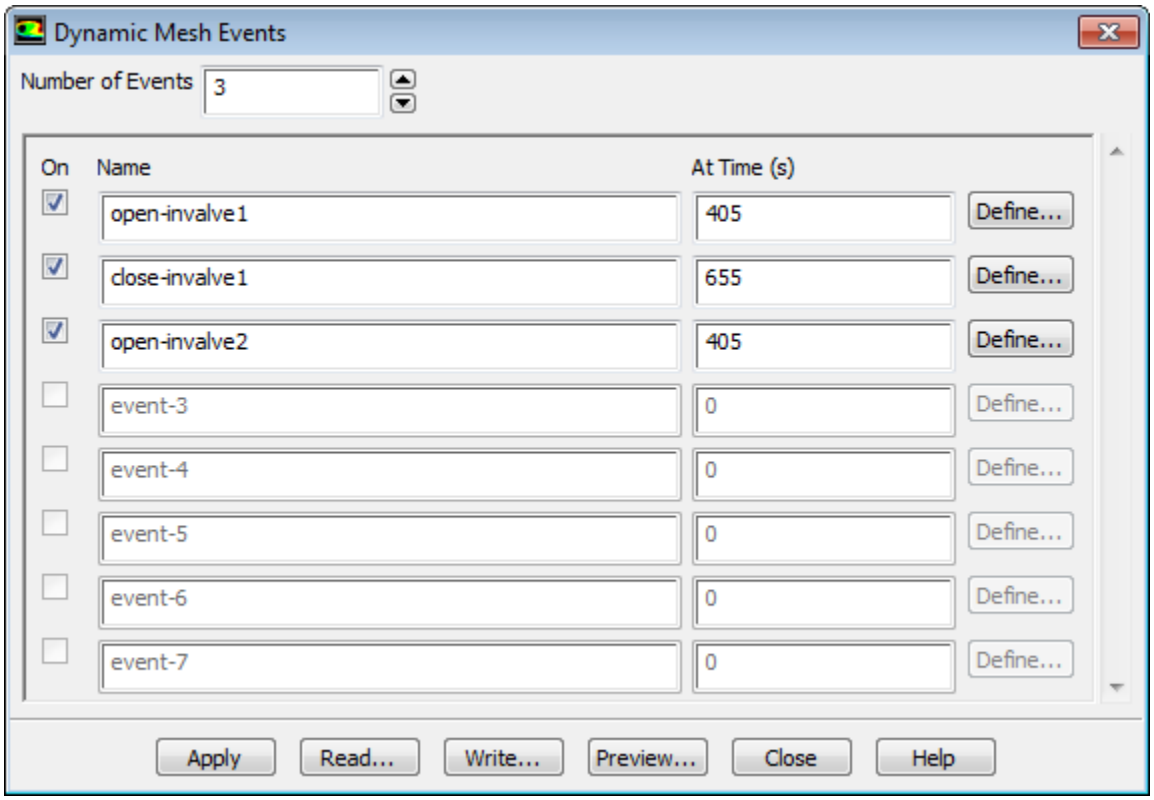
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Create Zone
allows you to create a new flow control zone of the specified name.

Delete Zone
allows you to delete the selected flow zone.

37.10.7. Dynamic Mesh Events Dialog Box

The **Dynamic Mesh Events** dialog box is available to control the timing of specific events during the course of the simulation. See Defining Dynamic Mesh Events (p. 713) for details.



Controls

Number of Events
specifies the number of events to be defined.

On
enables the corresponding event.

Name
specifies the name of the event.

At Crank Angle
specifies the angular location of the crank at which the event should occur. This option appears for in-cylinder flows.

At Time
specifies the time (in seconds) at which you want the event to occur. This option appears for non-in-cylinder flows.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Define...
opens the Define Event Dialog Box (p. 2487).

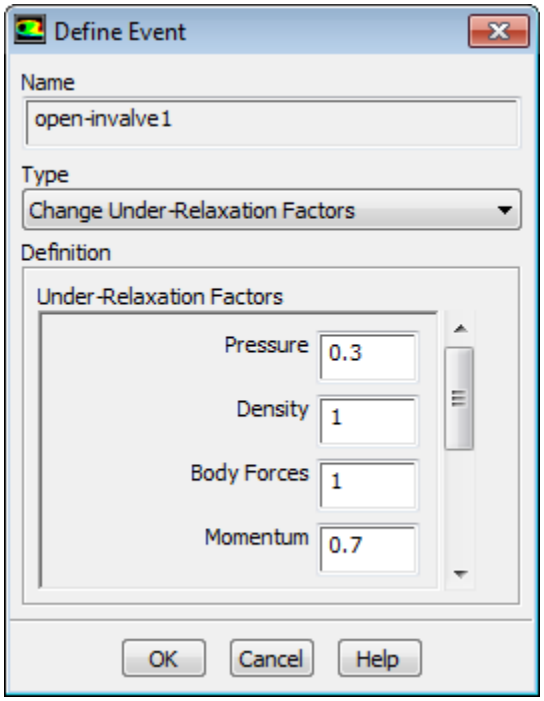
Read...
opens The Select File Dialog Box (p. 19).

Write...
opens The Select File Dialog Box (p. 19).

Preview...
opens the Events Preview Dialog Box (p. 2489).

37.10.8. Define Event Dialog Box

The **Define Event** dialog box allows you to define events.



Controls

Name
contains the name of the event to be defined.

Type
specifies the type of event. You can choose the type of event from the drop-down list. These event types and their definitions are described in Events (p. 716).

Definition
contains the input parameters corresponding to the type of event selected under **Type**.

Zone
contains a selectable list of the zones. The selection specifies the name of the zone(s) to be changed. This item will appear only for the **Change Zone Type** event.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

New Zone Type
specifies the type of zone to which an existing zone must be changed. This item will appear only for the **Change Zone Type** event.

From Zone
specifies the name of the zone from which the boundary condition is to be copied. This item will appear only for the **Copy Zone BC** event.

To Zone(s)
specifies the name of the zone to which the boundary condition is to be copied. This item will appear only for the **Copy Zone BC** event.

Zone(s)
contains a selectable list of the zones. The selection specifies the name of the zone to be activated/de-activated. This item will appear only for the **Activate Cell Zone** and **Deactivate Cell Zone** events.

Interface Name
contains the name of the interface to be created or deleted. This item will appear only for the **Create Sliding Interface** and **Delete Sliding Interface** events.

Interface Zone 1, Interface Zone 2
specifies the two zones on either side of the interface to be created. This item will appear only for the **Create Sliding Interface** event.

Wall 1 Motion, Wall 2 Motion
specifies the dynamic zones whose motion can be copied for the zones specified under **Interface Zone 1** and **Interface Zone 2**. This item will appear only for the **Create Sliding Interface** event.

Attribute
allows you to select the relevant motion attribute. This item will appear only for the **Change Motion Attribute** event.

Status
allows you to enable or disable the motion attribute. This item will appear only for the **Change Motion Attribute** event.

Dynamic Mesh Zones
contains a list of dynamic zones. This item will appear only for the **Change Motion Attribute** event.

Crank Angle Step Size
specifies the new physical time step value in degrees. This item will appear only for the **Change Time Step Size** event.

Base Dynamic Zone
specifies the zone from which the layer of cells is to be created. This item will appear only for the **Insert Boundary Layer** and **Remove Boundary Layer** event.

Side Dynamic Zone
represents the deforming face zone adjacent to the **Base Dynamic Zone** before the layer is inserted. This item will appear only for the **Insert Boundary Layer** event.

Internal Zone 1 Name, Internal Zone 2 Name
specifies the name of the new internal zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Time Step Size
allows you to change the time step size of the event. This item will appear only for the **Change Time Step Size** event.

Under-Relaxation Factors
allows you to specify the under-relaxation factors for the selected event. This item will appear only for the **Change Under-Relaxation Factors** event. See Setting Under-Relaxation Factors (p. 1564) for details.

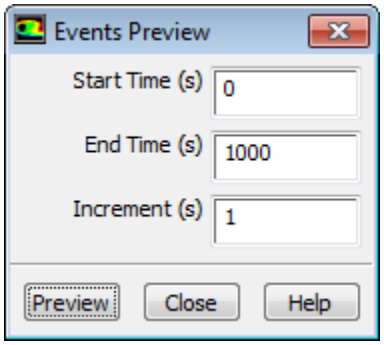
Adjacent Dynamic Face Zone
allows you to select the dynamic face zone adjacent to the location of the cell layer to be inserted (or deleted). You can select the required zone from the drop-down list.

Direction Parameter
is the direction with respect to the selected dynamic face zone a layer of cells is removed or added.

Command
specifies the series of text / Scheme commands or the macro to be executed during the simulation. This item will appear only for the **Execute Command** event.

37.10.9. Events Preview Dialog Box

The **Events Preview** dialog box allows you to play the events to check that they are defined correctly.



Controls

Start Crank Angle
specifies the crank angle at which you want to start the preview (for in-cylinder flows).

Start Time
specifies the time at which you want to start the preview (for non-in-cylinder flows).

End Crank Angle
specifies the crank angle at which you want to end the preview (for in-cylinder flows).

End Time
specifies the time at which you want to end the preview (for non-in-cylinder flows).

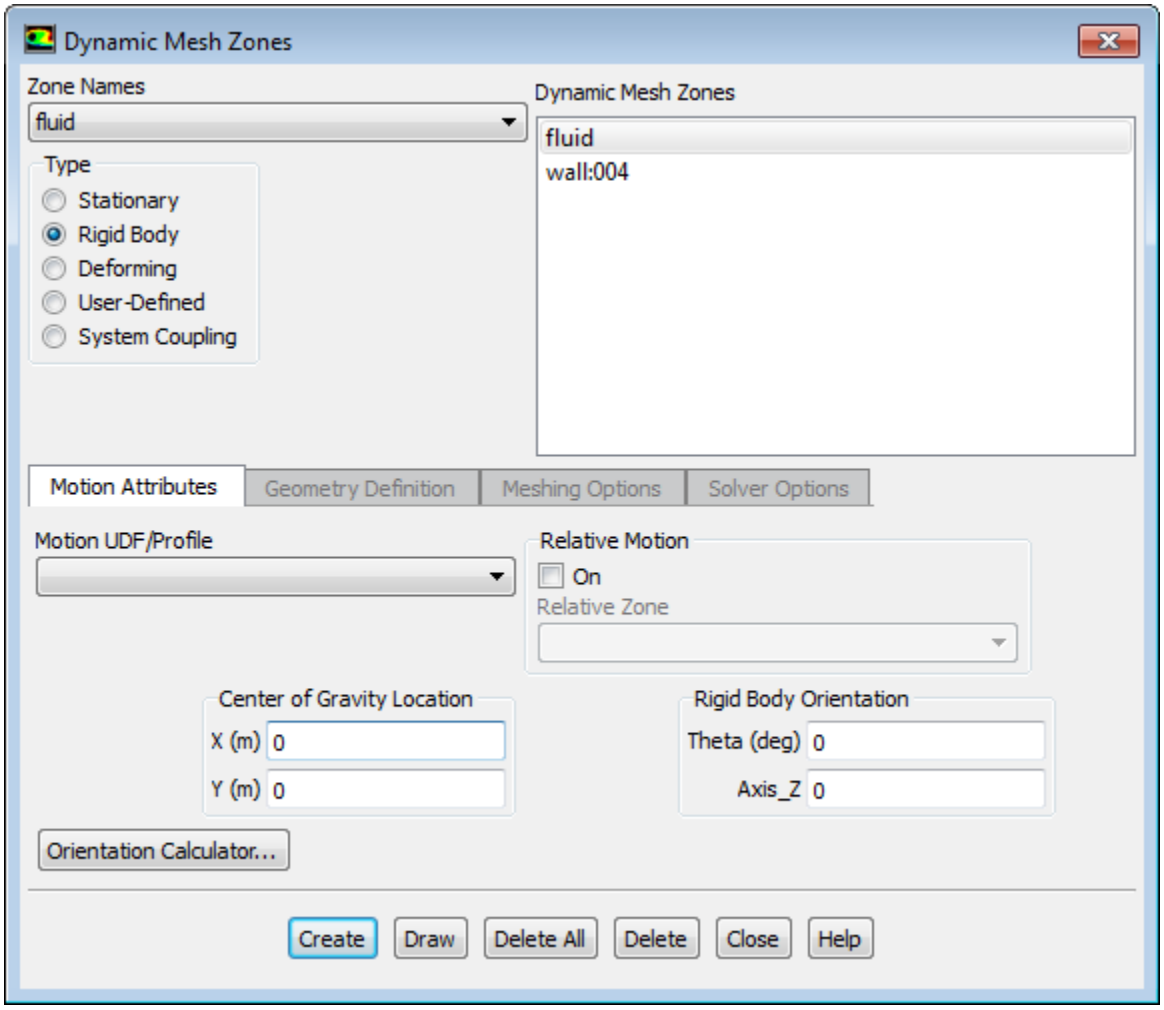
Increment
specifies the size of the step to take during the preview.

Preview
plays back the events at the crank angle specified for each event and reports when each event occurs in the text (console) window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.10.10. Dynamic Mesh Zones Dialog Box

The **Dynamic Mesh Zones** dialog box allows you to specify the motion of the dynamic zones in your model. See Specifying the Motion of Dynamic Zones (p. 722) for details.



Controls

Zone Names
contains the names of the zones in the model.

Type
contains the types of motion that can be specified for a dynamic zone.

Stationary
explicitly declares the zone as stationary, so that the nodes on this zone are excluded when updating the node positions. See Specifying the Motion of Dynamic Zones (p. 722) for more information.

Rigid Body
specifies the zone as having a rigid-body motion.

Deforming
specifies the zone as deforming.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Defined
enables you to specify a user-defined zone motion.

System Coupling
allows the zone to be involved in a system coupling simulation where the motion is defined by the application that ANSYS Fluent is coupled with on this zone (see the Fluent in Workbench User's Guide and the System Coupling Guide for more details). Once enabled, the **Solver Options** tab can be used to help achieve convergence for system coupling cases where the physics is strongly coupled. If a dynamic mesh zone of the type **System Coupling** exists, and ANSYS Fluent is not involved in a system coupling simulation, then this zone type behaves in the same way as a stationary zone.

Dynamic Mesh Zones
lists all of the dynamic zones in the case.

Motion Attributes
contains parameters to specify the motion attributes for a rigid-body-motion zone and a user-defined-motion zone.

Motion/UDF Profile
allows you to define the motion of the rigid body zone by selecting a profile or user-defined function from the drop-down list. See Profiles (p. 435) and Solid-Body Kinematics (p. 739) for information on profiles, and see the Fluent Customization Manual for information on user-defined functions.

Six DOF UDF/Properties

allows you to define the motion of a rigid body zone by selecting a profile, user-defined function, or set of six DOF properties (created using the Six DOF Properties Dialog Box (p. 2482)) from the drop-down list. This option is available only when **On** is enabled in the **Six DOF** group box.

Six DOF
contains parameters for the **Six DOF** solver.

On
enables the use of the **Six DOF** solver.

Passive
(if enabled) does not take forces and moments on the zone into consideration.

Center of Gravity Location

contains the current values of the coordinates for the location of the center of gravity / rotation of the selected zone. This item will appear only if the motion **Type** is **Rigid Body** and **In-Cylinder** is not enabled in the **Dynamic Mesh** task page.

Relative Motion
allows you to specify the motion of the dynamic zone as relative to another pre-defined rigid body zone. This group box will only appear if the **Type** is **Rigid Body** or **User-Defined**; for the latter, the **Relative Zone** must be a cell zone.

Rigid Body Orientation
contains the current values of the coordinates for the orientation of the rigid body of the selected zone. This item will appear only if the motion **Type** is **Rigid Body** and **In-Cylinder** is not enabled in the **Dynamic Mesh** task page.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Center of Gravity Velocity

specifies the velocity of the center of gravity / rotation with respect to inertia coordinate system. This option is available only if the **Six DOF** solver is the selected model.

Rigid Body Angular Velocity

specifies the angular velocity of the rigid body with respect to inertia coordinate system. This option is available only if the **Six DOF** solver is the selected model.

Lift/Stroke

contains the current value of valve lift or piston stroke, which is automatically updated when you click **Create**. This item will appear only if **In-Cylinder** is enabled in the **Dynamic Mesh** task page.

Valve/Position Axis

specifies the direction of the reference axis of the valves or piston for an in-cylinder problem. This item will appear only if **In-Cylinder** is enabled in the **Dynamic Mesh** task page.

Mesh Motion UDF

allows you to select the user-defined function that defines the geometry and motion of the zone. This item will appear only if the motion **Type** is **User-Defined**.

Exclude Mesh Motion in Boundary Conditions

allows you to specify that the boundary mesh motion should not be included in the physical boundary conditions of that zone. This option is only available for non-periodic boundary zones.

Geometry Definition

contains parameters to define a deforming zone.

Definition

allows you to select a geometry definition to project nodes of the deforming zone on. Available options are **faceted**, **plane**, **cylinder**, and **user-defined**.

Feature Detection

allows you to preserve features for 3D cases on boundary zones of type **Deforming** or **User-Defined**. Such features may be at the juncture of different boundary zones, or they may be on a single non-planar boundary zone.

Include Features

enables the detection and preservation of features of a particular angular range.

Feature Angle

defines a threshold value in degrees. For details on how this angle is defined, see Feature Detection (p. 690).

Point on Plane

allows you to specify the position of a point on the plane. This item will appear only when you select **plane** for the **Definition**.

Plane Normal

allows you to specify the direction of the plane normal. This item will appear only when you select **plane** for the **Definition**.

Cylinder Radius

allows you to specify the radius of the cylinder. This item will appear only when you select **cylinder** for the **Definition**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cylinder Origin
allows you to specify the location of the cylinder origin. This item will appear only when you select **cylinder** for the **Definition**.

Cylinder Axis
allows you to specify the direction of the cylinder axis. This item will appear only when you select **cylinder** for the **Definition**.

Geometry UDF
allows you to select a user-defined function for a geometry **Definition**.

Meshing Options
contains parameters for various meshing options.

Adjacent Zone
contains the name of the adjacent zone that is involved in local remeshing or dynamic layering. This item will appear only if the zone type is **Stationary**, **Rigid Body**, or **User-Defined**, and if the zone is not the boundary of a CutCell dynamic cell zone.

Cell Height
allows you to specify the ideal height of the adjacent cells as either a constant value or a compiled user-defined function. This item will appear only if the motion **Type** is **Stationary**, **Rigid Body**, or **User-Defined**, and if the zone is not the boundary of a CutCell dynamic cell zone.

Deform Adjacent Boundary Layer with Zone
enables the smoothing of an adjacent boundary layer mesh. This option is not available when **Stationary** or **Deforming** is selected in the **Type** list.

Methods
contains options to specify the mesh update method(s) and controls on a zone by zone basis. These options and parameters will override those that you specified globally in the **Dynamic Mesh** task page. This item will appear only if the motion **Type** is **Deforming**.

Smoothing
enables the smoothing mesh update method.

Layering
enables the layering mesh update method (valid for a prismatic cell zone only). This item will appear only if the zone you are defining is a cell (fluid) zone.

Remeshing
enables the remeshing mesh update method.

Smoothing Elements
allows you to specify the element types for which spring-based smoothing is used. This item will only be available if you have selected a cell zone and if spring-based smoothing has been enabled.

Global Settings
specifies that the zonal settings are the same as set globally in the **Mesh Method Settings** dialog box (see Applicability of the Spring-Based Smoothing Method (p. 649) or Mesh Method Settings Dialog Box (p. 2474)).

Tet in Tet Zones
(3D only) specifies that this zone will only get smoothed if it consists entirely of tetrahedral elements.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tri in Tri Zones
(2D only) specifies that this zone will only get smoothed if it consists entirely of triangular elements.

Tet in Mixed Zones
specifies that all simplex elements in this zone should get smoothed. All other elements in a mixed element zone will not undergo smoothing.

All
specifies that all element types in this zone will get smoothed.

Zone Parameters
contains a set of remeshing criteria that, if revised (with reasonable values), will be used for the dynamic zone rather than those you specified globally in the **Remeshing** tab of the **Mesh Method Settings** dialog box. Note that this group box is not available if the **CutCell** option in the **Remeshing Options** group box is enabled.

Minimum Length Scale
allows you to specify the minimum length scale for the zone. This item will appear only if the zone you are defining is a cell (fluid) zone.

Maximum Length Scale
allows you to specify the maximum length for the zone. This item will appear only if the zone you are defining is a cell (fluid) zone.

Maximum Skewness
allows you to specify the desired value for maximum skewness.

Zone Scale Info...
opens the Zone Scale Info Dialog Box (p. 2499), in which you can view the statistics of the mesh, such as minimum, maximum, and average length scale values, as well as the maximum skewness.

CutCell Zone Parameters
contains a set of global parameters used for CutCell zone remeshing. This group box will only appear if the zone selected in the **Dynamic Mesh Zones** list is a cell zone, and if the **CutCell** option is enabled in the **Remeshing Options** group box.

Maximum Mesh Size
allows you to specify the maximum mesh size of the Cartesian CutCell mesh.

Growth Rate
allows you to specify the default growth rate used for mesh refinement by size functions. This growth rate is used during remeshing by the mesh-based size functions of all boundaries of the CutCell cell zone that are not defined as dynamic mesh zones.

Minimum Orthogonal Quality
allows you to specify the minimum allowable orthogonal quality for the cell zone. CutCell remeshing will occur if the orthogonal quality for any cell in the cell zone drops below this value.

Remeshing Interval
specifies the interval of time steps at which the cell zone remeshing will take place, even if the mesh quality has not deteriorated below the value entered for **Minimum Orthogonal Quality**. Enter a value of `0` for the **Remeshing Interval** if you want the remeshing to occur only if there is insufficient mesh quality.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Inflation Layers
allows you to enable inflation layers on the CutCell cell zone and specify global inflation parameters.

Settings...
opens the Inflation Settings Dialog Box (p. 2498), which allows you to enter the global inflation parameters used by default on all boundary zones.

Boundary Zones Info...
opens the CutCell Boundary Zones Info Dialog Box (p. 2498), which lists all of the boundary zones for the CutCell dynamic cell zone, along with the remeshing and inflation layer parameters.

Zone Scale Info...
opens the Zone Scale Info Dialog Box (p. 2499), in which you can view the statistics of the mesh, such as minimum, maximum, and average length scale values, as well as the maximum skewness.

CutCell Boundary Zone Parameters
contains a set of local parameters used for CutCell zone remeshing. This group box will only appear if the zone selected in the **Dynamic Mesh Zones** list is a boundary of a CutCell dynamic cell zone.

Maximum Mesh Size
allows you to specify the maximum mesh size used by the soft size function. If a value of `0` is entered, a mesh-based size function is used to locally refine the Cartesian mesh near the boundary.

Growth Rate
allows you to specify the local growth rate used by the size function.

Zonal Inflation Layer Control
allows you to enable local inflation layer control and specify local inflation parameters. This option is only available if **Inflation Layers** has been enabled for the CutCell dynamic cell zone. If **Zonal Inflation Layer Control** is not enabled, then the global inflation parameters specified for the cell zone are used.

Settings...
opens the Inflation Settings Dialog Box (p. 2498), which allows you to enter local inflation parameters for the CutCell boundary zone.

Zone Scale Info...
opens the Zone Scale Info Dialog Box (p. 2499), in which you can view the statistics of the mesh, such as minimum, maximum, and average length scale values, as well as the maximum skewness.

Smoothing Methods
contains two methods of smoothing. This option is only available if spring-based smoothing has been selected in the **Mesh Method Settings** dialog box.

Spring
enables spring-based smoothing method.

Laplace
enables Laplacian smoothing method.

Remeshing Methods
contains two methods of remeshing. This group box will appear only when the motion **Type** is **Deforming**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Region
enables region-based remeshing method.

Local
enables local remeshing method.

Remeshing Method
provides settings for local face remeshing of the dynamic zone. This group box will appear only for boundary zones, when the motion **Type** is **User-Defined**.

Local
enables local face remeshing for the dynamic zone. This option is only available when **Local Face** is enabled in the **Remeshing** tab of the Mesh Method Settings Dialog Box (p. 2474).

Maximum Skewness
is a field that, if revised (with a reasonable value), sets a maximum skewness for the local face remeshing of the dynamic zone that is different than the global value set in the **Remeshing** tab of the Mesh Method Settings Dialog Box (p. 2474).

Remeshing Options
contains one method of remeshing.

CutCell
enables the CutCell zone remeshing method. This option is only available when the **CutCell Zone** is enabled in the **Mesh Method Settings** dialog box, and if the zone selected in the **Dynamic Mesh Zones** list of the **Dynamic Mesh Zones** dialog box is a cell zone.

Solver Options
contains parameters for various solver options for system coupling and six DOF dynamic mesh zones. See System Coupling Motion (p. 738) for more information.

Solution Stabilization
enables/disables solution stabilization settings for system coupling and six DOF dynamic mesh zones.

Stabilization Parameters
contains options for solution stabilization settings.

Scale Factor
allows you to set the scale factor used by the selected **Method** for convergence stabilization.

Method
Stabilization is achieved through a boundary source coefficient introduced in the continuity equation. It is designed to improve the diagonal dominance of the matrix system in the cells adjacent to system coupling boundaries. Two methods for this boundary source coefficient are available:

volume-based
(default) specifies that the diagonal entry of the linear matrix system corresponding to the discretized continuity equation is re-scaled using the cell volume and a scale factor, according to Equation 10.32 (p. 739).

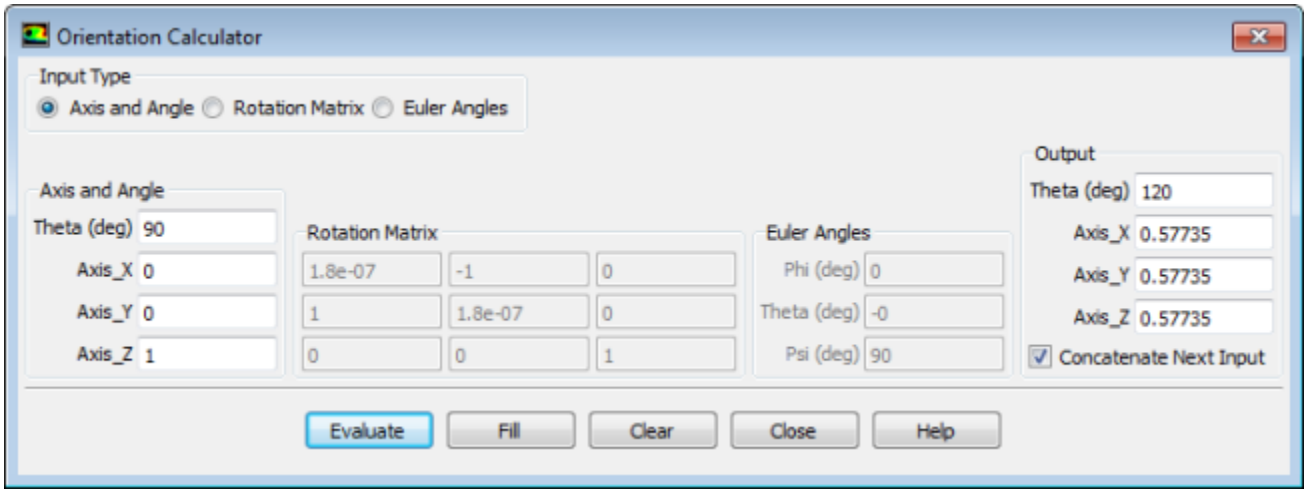
coefficient-based
specifies that the diagonal entry of the linear matrix system corresponding to the discretized continuity equation is directly re-scaled by a scale factor, according to Equation 10.33 (p. 739).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.10.11. Orientation Calculator Dialog Box

The **Orientation Calculator** dialog box allows you to convert rotation matrices and Euler angles to axis and angle format. It also allows you to concatenate rotations to determine a rigid body's final orientation.

Figure 37.1: Orientation Calculator Dialog Box



Controls

Input Type
allows you to select which method you will use to enter your rigid body orientation values. For additional information about these input types, see Rigid Body Motion (p. 726).

Axis and Angle
allows you to enter the angle of rotation and the axis about which the rigid body is rotating.

Rotation Matrix
allows you to enter the orientation of the rigid body as a rotation matrix.

Euler Angles
allows you to enter the orientation of the rigid body as a set of Euler Angles. For an explanation of which Euler angles method Fluent uses, see Rigid Body Motion (p. 726).

Output
displays the angle of rotation and the axis about which the rigid body is rotating after you click **Evaluate**.

Note that if you enter a single orientation in **Axis and Angle** and click **Evaluate**, the values shown in **Output** will be the same as you entered in **Axis and Angle**

Concatenate Next Input
concatenates the next input entered (after clicking **Evaluate**) to the values displayed in **Output**

Evaluate
converts the specified input values into angle and axis format and displays the results in **Output**.

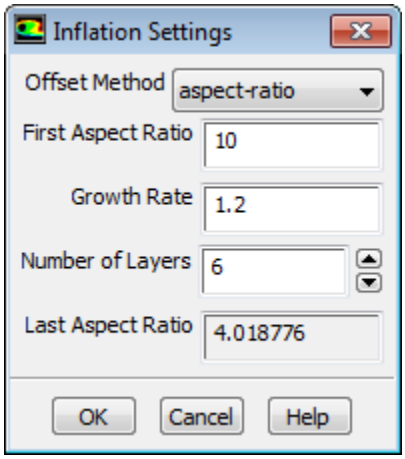
Note that the calculator also converts the entered values into the other two "grayed-out" input formats.

Fill
enters the values displayed in **Output** into the **Rigid Body Orientation** field of the **Dynamic Mesh Zones** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.10.12. Inflation Settings Dialog Box

The **Inflation Settings** dialog box allows you to enter inflation layer parameters for a dynamic zone.



Controls

Offset Method
allows you to select how the first layer height is evaluated. The **constant** type will use the same first height for all elements. The **aspect-ratio** type will evaluate local first heights such that the aspect ratio (base size divided by the element height) of the resulting elements is constant.

First Aspect Ratio
allows you to specify the aspect ratio of the first element if the **Offset Method** is set to **aspect-ratio**.

First Height
allows you to specify the height of the first element if the **Offset Method** is set to **constant**.

Growth Rate
allows you to specify the geometric growth rate of the inflation element heights.

Number of Layers
allows you to specify the number of elements in the inflation layer.

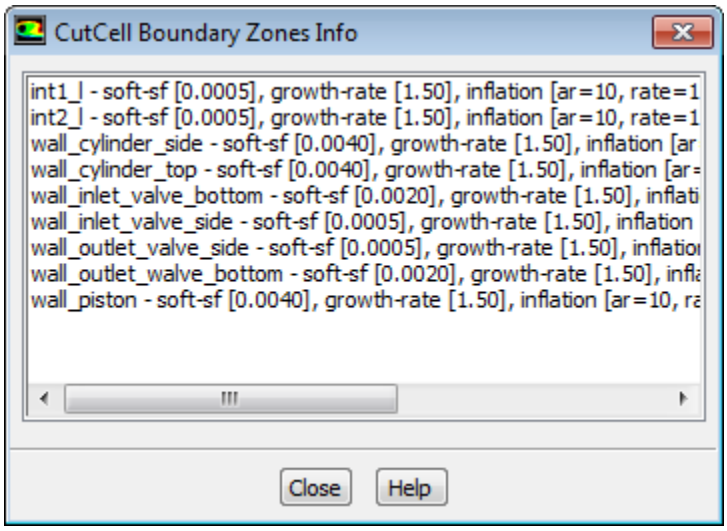
Last Aspect Ratio
displays the aspect ratio of the last element for the given set of parameters if the **Offset Method** is set to **aspect-ratio**.

Total Height
displays the overall thickness of the inflation layer if the **Offset Method** is set to **constant**.

37.10.13. CutCell Boundary Zones Info Dialog Box

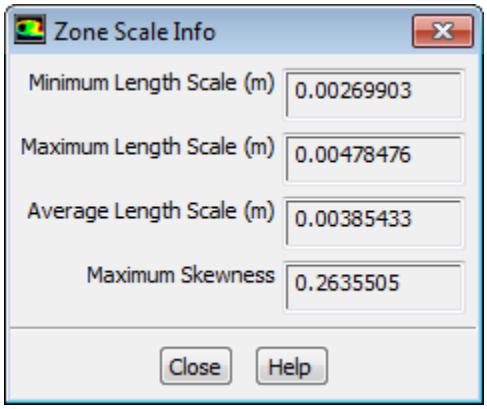
The **CutCell Boundary Zones Info** dialog box displays a list of all of the boundary zones for the CutCell dynamic cell zone. This list also provides the remeshing parameters for the zones, including size function type, the maximum mesh size, the growth rate used to refine the mesh at all of the CutCell boundaries. The inflation layer settings used on all boundaries are also shown.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



37.10.14. Zone Scale Info Dialog Box

The **Zone Scale Info** dialog box allows you to inspect the values of minimum and maximum cell area or volume, and maximum cell skewness in a zone.



Controls

Maximum Length Scale
displays the maximum cell length in the zone.

Minimum Length Scale
displays the minimum cell length in the zone.

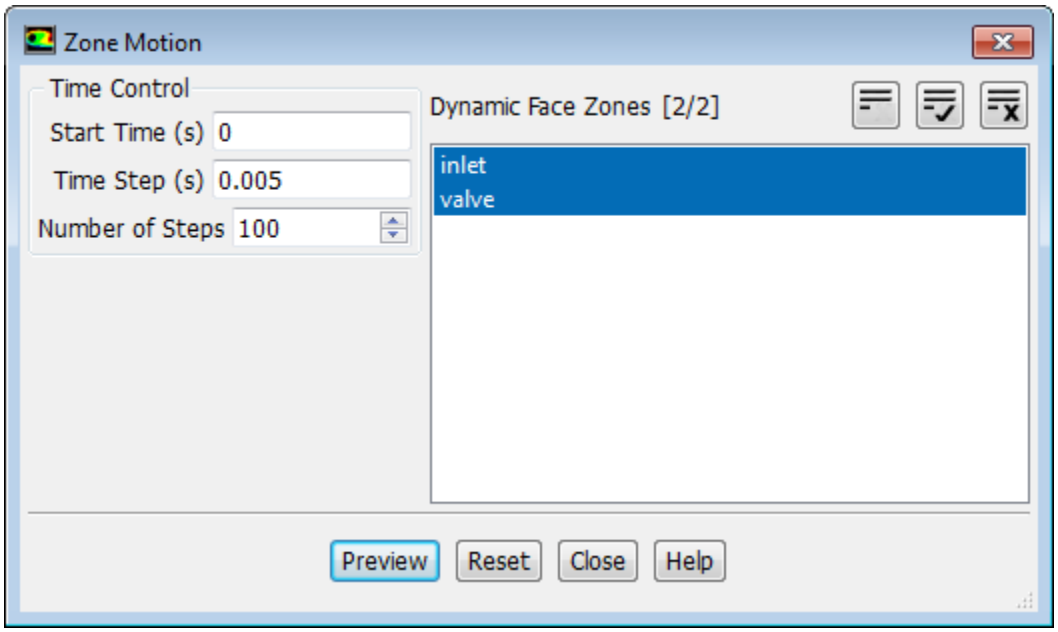
Average Length Scale
displays the average cell length in the zone.

Maximum Skewness
displays the maximum cell skewness in the zone.

37.10.15. Zone Motion Dialog Box

The **Zone Motion** dialog box will display the motion of zones specified with **Rigid Body** or **User-Defined** motion. See Previewing the Dynamic Mesh (p. 742) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Time Control
contains controls to specify the time intervals at which to display the motion.

Start Time (s)
specifies the time from which to start the zone motion preview.

Time Step (s)
specifies time step size for zone motion preview.

Number of Steps
specifies number of time steps for zone motion preview.

Dynamic Face Zones
allows you to select the dynamic face zones to preview. Only **User-Defined** or **Rigid Body** zones are available.

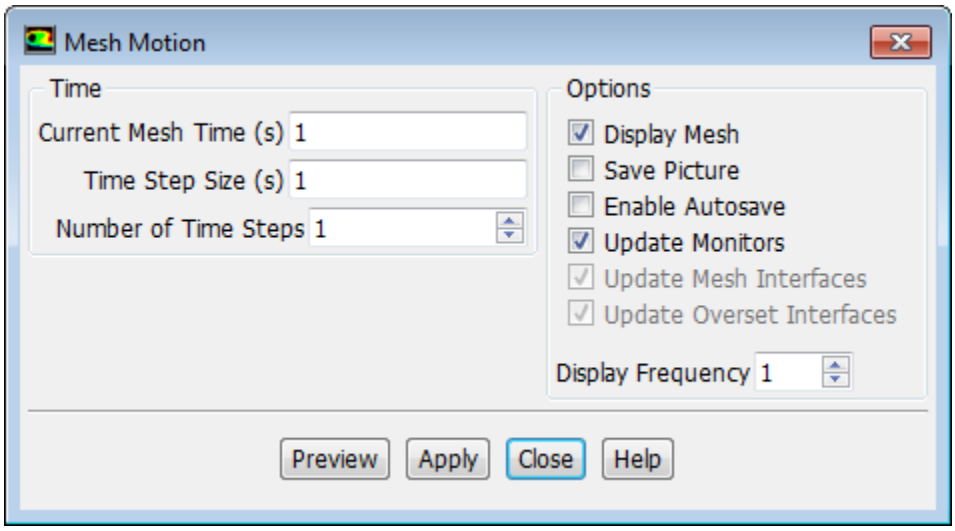
Preview
previews the zone motion.

Reset
resets the zone display and the dialog box inputs.

37.10.16. Mesh Motion Dialog Box

The **Mesh Motion** dialog box allows you to preview the dynamic mesh as it changes with time before you start your simulation. See Previewing the Dynamic Mesh (p. 742) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Time
contains the parameters to specify the time interval at which to update the mesh.

Current Mesh Time
displays the current time after the dynamic mesh has been advanced the specified number of steps.

Time Step Size
specifies the size of each time step.

Number of Time Steps
specifies the number of time steps.

Options
contains options to view the updated mesh.

Display Mesh
displays the mesh.

Save Picture
opens the Save Picture Dialog Box (p. 2568), allowing you to save a picture file of the mesh each time ANSYS Fluent updates it during the mesh preview.

Enable Autosave
opens the Autosave Case During Mesh Motion Preview Dialog Box (p. 2502), allowing you to save the case and data files with the specified name and frequency. See Automatic Saving of Case and Data Files (p. 48) for details.

Update Mesh Interfaces
allows you to update the interface at every time step.

Update Monitors
allows you to disable the processing of monitors and computation activities during mesh motion preview.

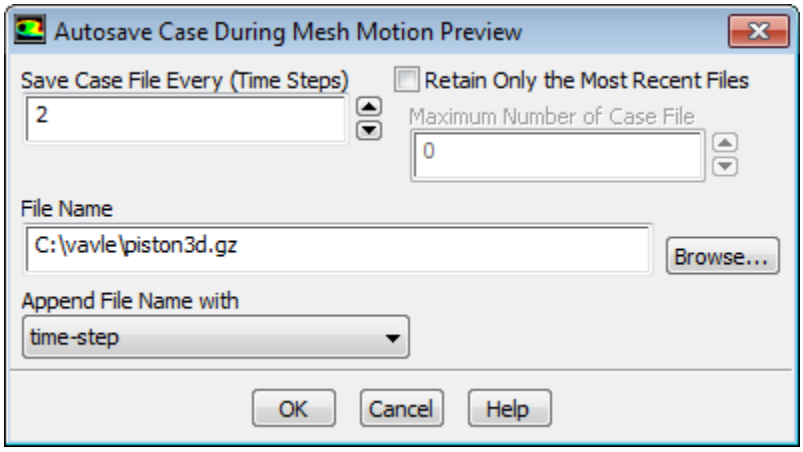
Display Frequency
displays the frequency at which ANSYS Fluent will update the mesh display.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Preview
allows you to preview the motion of the selected zones in the graphics window.

37.10.17. Autosave Case During Mesh Motion Preview Dialog Box

The **Autosave Case During Mesh Motion Preview** dialog box allows you to automatically save your case during the dynamic mesh preview as it changes with time, while running your simulation. See Automatic Saving of Case and Data Files (p. 48) for details about the inputs.



Controls

Save Case File Every
contains the parameters to specify the time interval at which to update the mesh.

Retain Only the Most Recent Files
allows you to restrict the number of files saved by ANSYS Fluent if you have limited disk space. When this option is enabled, you can enter the appropriate value in the **Maximum Number of Data Files** field.

> **Note**
>
> Only the associated case files are retained when using this option.

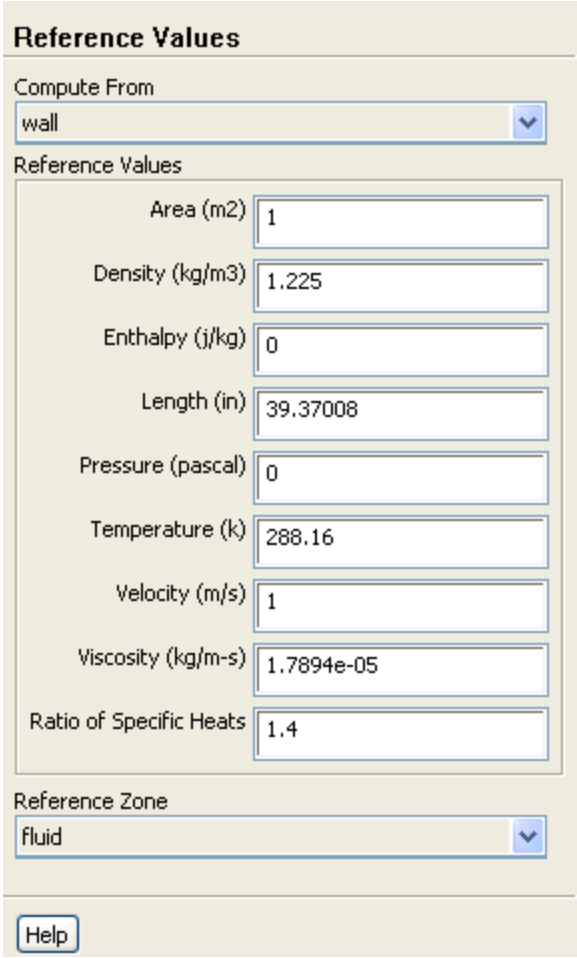
Maximum Number of Data Files
specifies the maximum number of data files that can be saved at any instance. If you have constraints on the disk space, you can restrict the number of files to be saved using this field. After saving the specified number of files, ANSYS Fluent will overwrite the earliest existing file. The default value for this field is zero, which saves all the files.

Append File Name with
allows you to select **flow-time** or **time-step** to be appended to the file name. This option is available only for unsteady-state calculations. The default selection is **flow-time**.

37.11. Reference Values Task Page

The **Reference Values** task page allows you to set the reference quantities used for computing normalized flow field variables. It also allows you to specify the reference zone for postprocessing relative velocities in moving-zone problems. See Reference Values (p. 1924) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Compute from
contains a drop-down list of the boundary zones. You may select a zone to be used for automatically defining the reference values, but depending on the boundary condition used, all of the reference values may not be set. For example, the reference length and area will not be set by computing the reference values from a boundary condition; you must set these manually.

Reference Values
contains inputs for the reference values.

Area
sets the reference area, which is used to compute the force and moment coefficients.

Depth
sets the reference depth used for computing cell volumes in 2D.

Density
sets the reference density, which is used to compute the reference dynamic pressure.

Enthalpy
sets the reference enthalpy, which is used to determine the total enthalpy change.

Length
sets the reference length, which is used in the computation of the moment coefficient.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pressure
sets the reference pressure, which is used to compute the pressure-related forces and moments and the pressure coefficient.

Temperature
sets the reference temperature, which is used to compute entropy for incompressible flows.

Velocity
sets the reference velocity magnitude, which is used to compute the reference dynamic pressure.

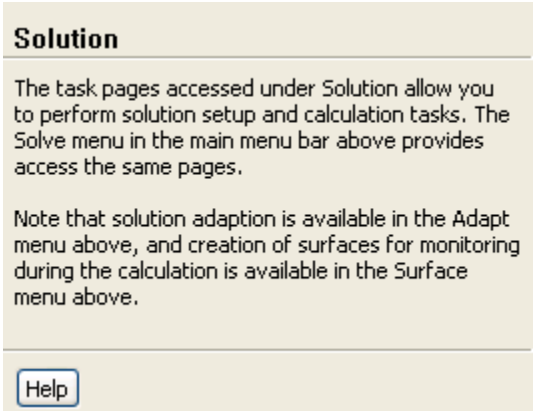
Viscosity
sets the reference kinematic viscosity, which is used in the computation of the boundary Reynolds number.

Ratio of Specific Heats
sets the value of the specific heat ratio, which is used in turbomachinery efficiency calculations.

Reference Zone
contains a drop-down list of all cell zones in the domain. For flows involving multiple moving zones, you must select the reference zone for postprocessing relative velocities and related quantities. See Setting the Reference Zone (p. 1927) for details.

37.12. Solution Task Page

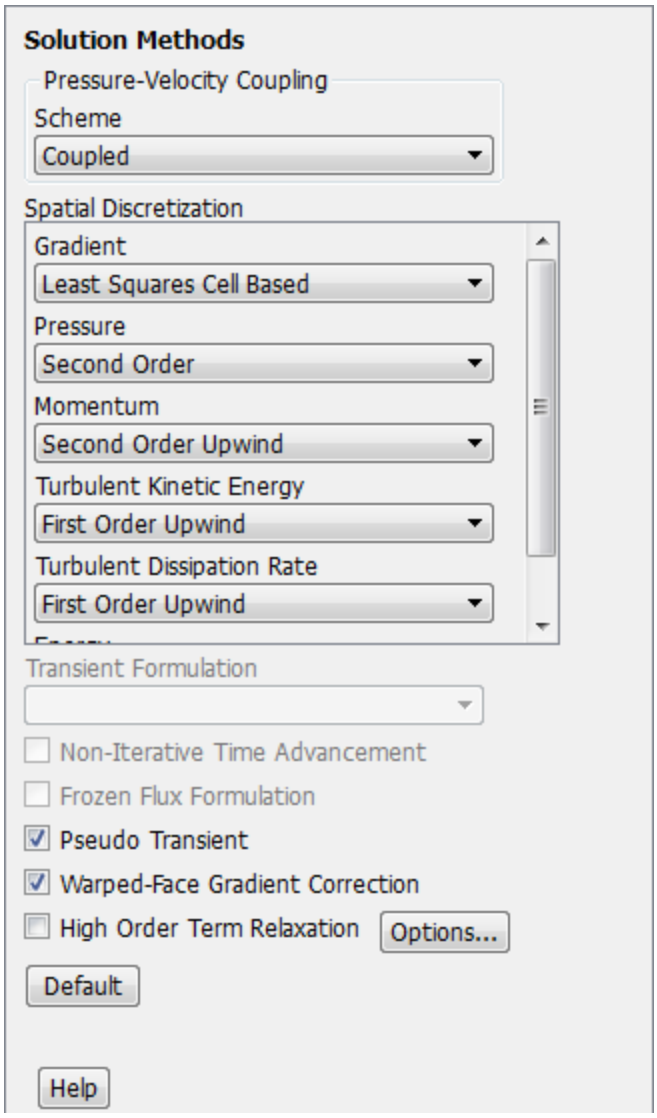
The **Solution** task page introduces you to the main tasks involved in solving your CFD simulation using ANSYS Fluent. For more information about using ANSYS Fluent to solve your CFD simulation, see Using the Solver (p. 1551).



37.13. Solution Methods Task Page

The **Solution Methods** task page allows you to specify various parameters associated with the solution method to be used in the calculation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Formulation

provides a drop-down list of the available types of solver formulations: **Implicit** and **Explicit**.

This item appears only when the density-based solver is used.

Flux Type

provides a drop-down list of the convective flux types: **Roe-FDS**, **AUSM**, and **Low Diffusion Roe-FDS**. Details about each of the flux types can be found in Convective Fluxes in the Theory Guide.

Pressure-Velocity Coupling

contains settings for pressure-velocity coupling schemes.

Scheme

(for the pressure-based solver only) provides a drop-down list of the available pressure-velocity coupling schemes: **SIMPLE**, **SIMPLEC**, **PISO**, and **Coupled**. When the non-iterative time advancement (NITA) scheme is enabled in the **Solution Methods** task page, **Fractional Step** is available for single phase flows, and **Phase Coupled SIMPLE** is available for Eulerian multiphase flows. See Pressure-Velocity Coupling in the *Fluent Theory Guide*, and Choosing the Pressure-Velocity Coupling Method (p. 1561),

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Solution Controls for the Non-Iterative Solver (p. 1566), and Selecting the Pressure-Velocity Coupling Method (p. 1507) for details about these methods.

Skewness Correction
enables the SIMPLEC and PISO skewness correction for highly skewed meshes if the value (number of iterations) is greater than 0. The default value is 0 for SIMPLEC and 1 for PISO.

Neighbor Correction
enables the PISO neighbor correction, which is recommended for transient calculations, if the value (number of iterations) is greater than 0. The default value is 1.

Skewness-Neighbor Coupling
allows for a more economical but a less robust variation of the PISO algorithm.

Coupled with Volume Fraction
couples velocity corrections, shared pressure corrections, and the correction for volume fraction simultaneously. This option is available in the interface after you have selected **Coupled** from the **Scheme** drop-down list for **Pressure-Velocity Coupling**.

Solve N-Phase Volume Fraction Equations
solves all primary and secondary volume fraction equations and scales the resulting volume fractions to satisfy the requirement that they sum to 1. If this is disabled, only the secondary phase volume fractions are solved directly and the primary phase volume fraction is set such that the volume fractions sum to 1.

Spatial Discretization
contains settings that control the spatial discretization of the convection terms in the solution equations. See Choosing the Spatial Discretization Scheme (p. 1554) for details.

Gradient
contains a drop-down list of the options for setting the method of computing the gradient in Equation 21.29 in the Theory Guide: **Green-Gauss Cell Based**; **Green-Gauss Node-Based**, and **Least Squares Cell Based**. See Evaluation of Gradients and Derivatives in the Theory Guide for details.

Pressure
(for the pressure-based solver only) contains a drop-down list of the discretization schemes available for the pressure equation: **Standard**, **PRESTO!**, **Linear**, **Second Order**, and **Body Force Weighted**.

This item appears only when the pressure-based solver is used.

Flow
(for the density-based solvers only) contains a drop-down list of the discretization schemes available for the pressure, momentum, and (if relevant) energy equations: **First Order Upwind**, **Second Order Upwind**, and **Third-Order MUSCL**.

This item appears only when one of the density-based solvers is used.

Momentum, Energy, and so on
are the names of the other convection-diffusion equations being solved. In the drop-down list next to each equation, you can select the **First Order Upwind**, **Second Order Upwind**, **Power Law**, **QUICK**, or **Third-Order MUSCL** discretization scheme for that equation.

If the LES turbulence model is enabled, then you have a choice of selecting **Bounded Central Differencing** or **Central Differencing** to solve the convection-diffusion equations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If one of the density-based solvers is used, **Momentum** and **Energy** will not appear. For the density-based solvers, the discretization scheme for these equations is selected in the **Flow** drop-down list (described above).

Volume Fraction

is available when the VOF multiphase model is enabled. The discretization schemes that are used when solving volume fraction equations for the VOF explicit scheme are **Geo-Reconstruct**, **Compressive**, **CICSAM**, **Modified HRIC**, and **QUICK**. The discretization schemes that are used when solving volume fraction equations for the VOF implicit scheme are **First Order Upwind**, **Second Order Upwind**, **Compressive**, **Modified HRIC**, **BGM** (steady state only), and **QUICK**. See Interpolation Near the Interface in the Theory Guide for detailed information about these VOF-specific interpolation schemes.

Transient Formulation

contains options for setting different time-dependent solution formulations. This option appears only when **Transient** is enabled under **Time** in the **General** task page. Available options include: **Explicit** (available only for the **Density Based Explicit** solver); **First Order Implicit**; **Second Order Implicit**; and **Bounded Second Order Implicit**. See Performing Time-Dependent Calculations (p. 1608) for details.

Non-Iterative Time Advancement

enables non-iterative time-advancement (NITA) scheme. See Time-Advancement Algorithm in the Theory Guide for details.

Frozen Flux Formulation

enables an option to discretize the convective part of Equation 21.63 in the Theory Guide using the mass flux at the cell faces from the previous time level n. This option is available only for a **Transient** solution. See The Frozen Flux Formulation in the Theory Guide for details.

Pseudo Transient

enables an option to apply the pseudo transient under-relaxation method, which is a form of implicit under-relaxation (see Pseudo Transient Under-Relaxation). This option is available for the pressure-based solver when **Coupled** is selected as the **Pressure-Velocity Coupling** scheme and for the density-based implicit solver. Note that this method can only be used when running a steady-state simulation.

Warped-Face Gradient Correction

enables an adjustment to the gradient discretization method that improves the gradient accuracy for meshes containing high aspect ratios, cells with non-flat faces, and highly deformed cells. By default, the fast, or more computationally efficient mode of the warped-face gradient correction is used. For additional information about the warped-face gradient correction, see Warped-Face Gradient Correction (p. 1674).

Convergence Acceleration For Stretched Meshes

Enable convergence acceleration for stretched meshes to improve the convergence of the implicit density based solver on meshes with high cell stretching (see Convergence Acceleration for Stretched Meshes (CASM) (p. 1573)).

High Order Term Relaxation

enables the relaxation of high order terms to aid in the solution behavior of flow simulations when higher order spatial discretization is used.

Options...

Opens the Relaxation Options Dialog Box (p. 2508).

Set All Species Discretizations Together

enables an option to use the same discretization scheme for all the species rather than setting each of the species individually. Notice that you will no longer see your list of individual species, instead a **Species**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

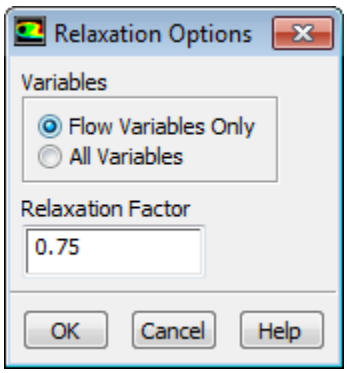
field will appear with the scheme of your choice. Note that this option is available when species transport is enabled.

Default
sets the fields to their default values, as assigned by ANSYS Fluent.

Report Poor Quality Elements
reports statistics on the number and type of cells that ANSYS Fluent has identified as having poor quality.

37.13.1. Relaxation Options Dialog Box

The **Relaxation Options** dialog box allows you to further control the **High Order Term Relaxation** as described in High Order Term Relaxation (HOTR) (p. 1557).



Controls

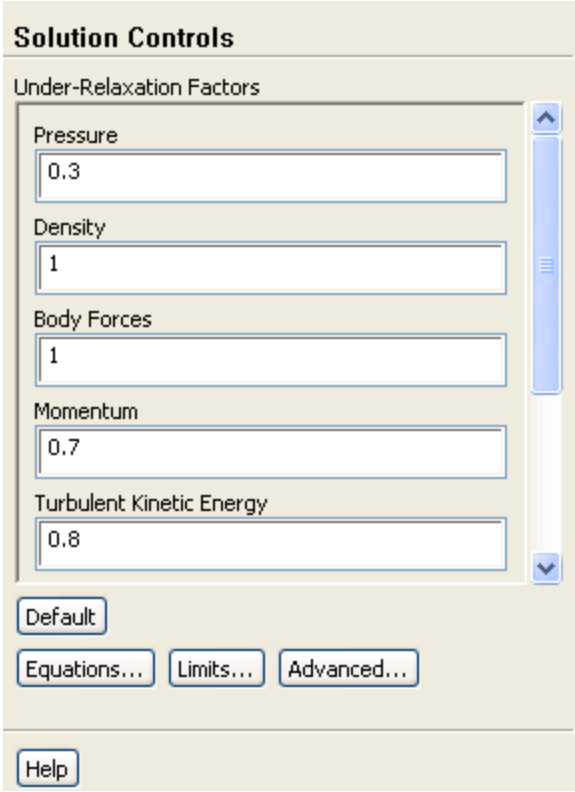
Variables
allows you to select between under-relaxing **All Variables** or only the default flow variables (**Flow Variables Only**.

Relaxation Factor
is by default 0.25 for steady-state cases and 0.75 for transient cases.

37.14. Solution Controls Task Page

The **Solution Controls** task page allows you to set common solution parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Courant Number

sets the fine-grid Courant number (time step factor) when the density-based solver is used. See Changing the Courant Number (p. 1571) for guidelines on setting the Courant number.

When the pressure-based solver is used for time-independent flows, and the **Coupled** pressure-velocity scheme is used, the **Courant Number** is used to stabilize the convergence behavior. See Under-Relaxation of Equations in the Theory Guide for a correlation of the under-relaxation factor and courant number.

Flow Courant Number

sets the Courant number for multiphase flow using the pressure-based coupled solver. The **Flow Courant Number** is used to stabilize the convergence behavior.

Volume Fraction Courant Number

sets the Courant number for multiphase flow using the pressure-based solver is coupled with the volume fraction. The default value is 200 and will appear in the interface when the **Coupled with Volume Fraction** option appears in the **Solution Methods** task page.

Explicit Relaxation Factors

for the **Coupled** scheme defines the explicit relaxation of variables between sub-iterations for momentum and pressure. See Under-Relaxation of Variables in the Theory Guide for information.

Multigrid Levels

specifies the maximum number of coarse levels to be created by the FAS multigrid solver. This item is the same as the **Max Coarse Levels** under **FAS Multigrid Controls** in the **Multigrid** tab of the Advanced Solution Controls Dialog Box (p. 2513), and it appears only when the density-based explicit solver is used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Residual Smoothing

contains parameters that govern the use of implicit residual smoothing. (See Implicit Residual Smoothing in the Theory Guide and Using Residual Smoothing to Increase the Courant Number (p. 1577) for details.) This section of the task page will appear only when the density-based explicit solver is used.

Iterations

sets the number of iterations of the Jacobi smoother to use. If **Iterations** is 0, then no implicit residual smoothing is performed.

Smoothing Factor

sets the implicit residual smoothing factor. This item will not appear unless **Iterations** is set to a non-zero value.

Under-Relaxation Factors

contains the under-relaxation factors for all equations that are being solved with the pressure-based solver. (See Setting Under-Relaxation Factors (p. 1564) for details.) In the field next to each equation, you can set the under-relaxation factor for that equation.

When one of the density-based solvers is used, **Under-Relaxation Factors** will appear only for the following variables, when they are included in your model: solid (for conjugate heat transfer models), turbulence variables, and viscosity. The solid under-relaxation factor is used to scale the CFL value in the solid region only if the under-relaxation value is set to a value less than 1. When the under-relaxation value is set to 1, then the solver ignores the specified CFL value for the solid and instead uses a very large value of CFL. This is done to speed up the convergence in the solid region. The density-based solvers use a segregated method to solve these equations; all the other equations are solved in a coupled manner, so there are no under-relaxation factors for them.

When **Non-Iterative Time Advancement** is selected for the pressure-based solver, the **Non-Iterative Solver Relaxation Factors** define the explicit relaxation (Under-Relaxation of Variables in the Theory Guide) of variables between sub-iterations and are used to prevent the solution from diverging.

When **Pseudo Transient** is selected (available with the pressure-based coupled solver), the **Pseudo Transient Explicit Relaxation Factors** can be specified (see Setting Pseudo Transient Explicit Relaxation Factors (p. 1602)).

Default

sets the fields to their default values, as assigned by ANSYS Fluent.

Equations...

displays the Equations Dialog Box (p. 2511).

Limits...

displays the Solution Limits Dialog Box (p. 2511).

Advanced...

displays the Advanced Solution Controls Dialog Box (p. 2513).

Set All Species URFs Together

enables an option to use the same under-relaxation factors for all the species rather than setting each of the species individually. Notice that you will no longer see your list of individual species, instead a **Species** field will appear with the specified under-relaxation factor. Note that this option is available when species transport is enabled.

For additional information, see the following sections:

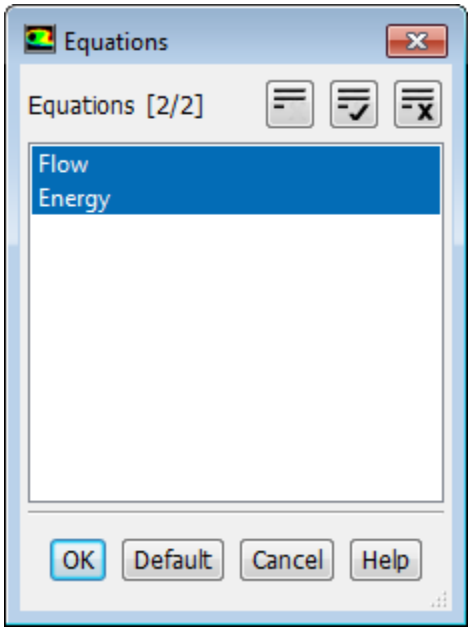
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.14.1. Equations Dialog Box
37.14.2. Solution Limits Dialog Box
37.14.3. Advanced Solution Controls Dialog Box

37.14.1. Equations Dialog Box

The **Equations** dialog box contains a list of the equations being solved for the current model. To temporarily disable solution of an equation, deselect it in this list and click **OK**. To re-enable the calculation for an equation, select it and click **OK**. See Step-by-Step Solution Processes (p. 1669) for details about using this feature in a step-by-step solution process.

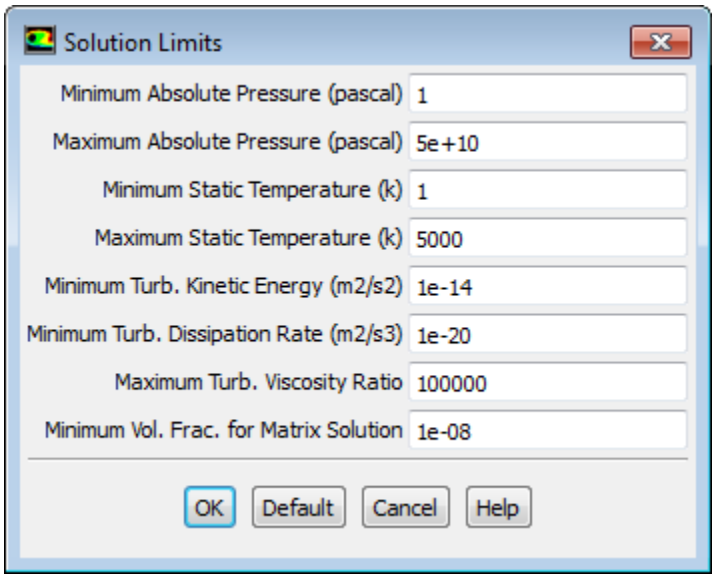
Note that, when one of the density-based solvers is used, **Energy** will not appear as a separate item in the **Equations** list. For the density-based solvers the energy equation is included in the **Flow** category (which also includes the pressure and momentum equations).



37.14.2. Solution Limits Dialog Box

The **Solution Limits** dialog box allows you to improve the stability of the solution. See Setting Solution Limits (p. 1586) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Minimum Absolute Pressure, Maximum Absolute Pressure
set the limiting minimum and maximum allowable values for absolute pressure.

Minimum Static Temperature, Maximum Static Temperature
set the limiting minimum and maximum allowable values for temperature.

Minimum Turb. Kinetic Energy
sets the limiting minimum value of turbulent kinetic energy (k) in the flow field. This parameter appears when one of the k- ε or k- ω models or the RSM is used.

Minimum Turb. Dissipation Rate
sets the limiting minimum value of turbulent dissipation rate (ε) in the flow field. This parameter appears when one of the k- ε models or the RSM is used.

Minimum Spec. Dissipation Rate
sets the limiting minimum value of specific dissipation rate (ω) in the flow field. This parameter appears when one of the k- ω models is used.

Maximum Turb. Viscosity Ratio
sets the limiting maximum allowable value of the ratio of turbulent to laminar viscosity (μ_t / μ). The turbulent viscosity is reduced to the necessary value so as not to exceed the maximum allowable viscosity ratio.

This parameter appears for all turbulent flows.

Minimum Vol. Frac. for Matrix Solution
sets the limiting minimum value for volume fraction in the matrix solution. This field appears for Eulerian multiphase simulations run on a double-precision solver.

Positivity Rate Limit
sets the limiting value for the rate of reduction of temperature. See Adjusting the Positivity Rate Limit (p. 1588) for details.

This item appears only when one of the density-based solvers is used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default

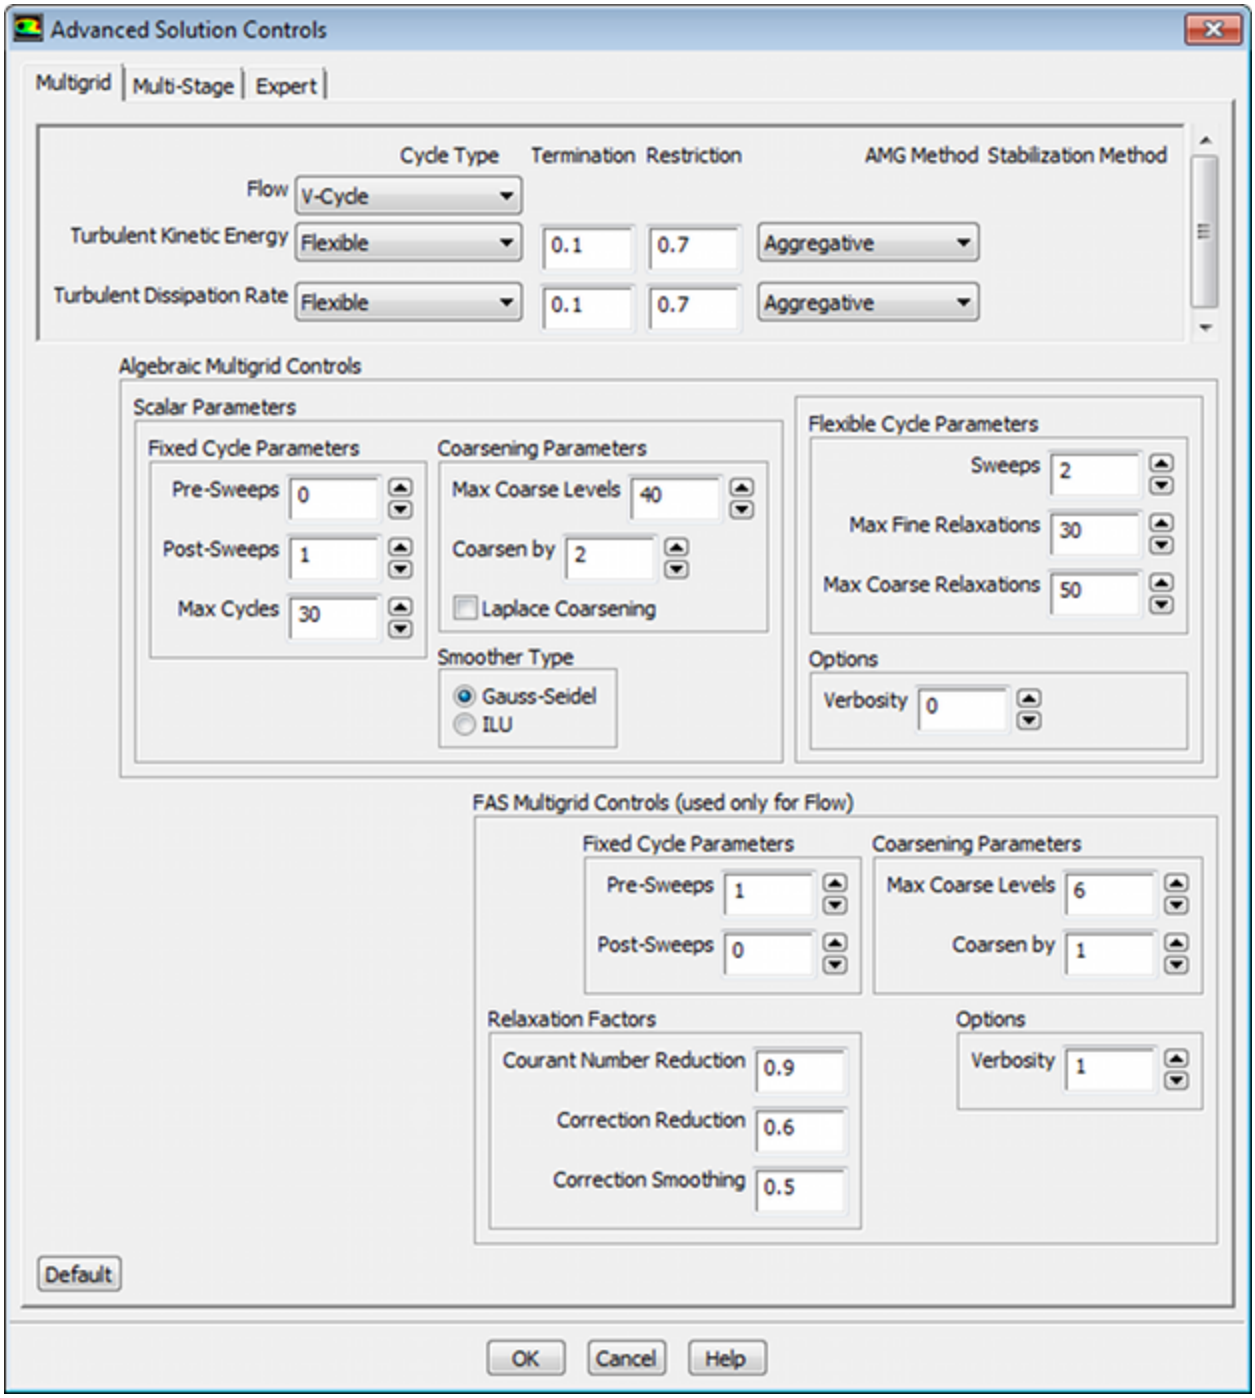
sets the fields to their default values, as assigned by ANSYS Fluent. After execution, the **Default** button becomes the **Reset** button.

Reset

resets the fields to their most recently saved values (for example, the values before **Default** was selected). After execution, the **Reset** button becomes the **Default** button.

37.14.3. Advanced Solution Controls Dialog Box

The **Advanced Solution Controls** dialog box allows you to set parameters related to the multigrid, multi-stage, and non-iterative solvers.



Controls

Multigrid

tab contains parameters related to the multigrid solver. See Modifying Algebraic Multigrid Parameters (p. 1670) and Setting FAS Multigrid Parameters (p. 1583) for details about the items below.

Cycle Type

contains a drop-down list for each equation that is being solved. From this list you can select the multigrid cycle type (**Flexible**, **V-Cycle**, **W-Cycle**, or **F-Cycle**). See Specifying the Multigrid Cycle Type (p. 1578) for details.

Note that, for the density-based solvers, the **Pressure**, **Momentum**, and **Energy** equations will not appear individually. They will instead be grouped together and called **Flow**.

Furthermore, for the density-based explicit solver, the **Cycle Type** choices for the **Flow** equations will be limited to **V-Cycle** and **W-Cycle**, while the choices for **Flow** for the density-based implicit solver will be limited to **V-Cycle** and **F-Cycle**.

Termination

specifies the termination criterion for each equation that is being solved using algebraic multigrid. See Setting the Termination and Residual Reduction Parameters (p. 1578) for details.

Restriction

specifies the residual reduction criterion for each equation that is being solved using the **Flexible** algebraic multigrid cycle. See Setting the Termination and Residual Reduction Parameters (p. 1578) for details. (This item will not appear for an equation that is using a **V-Cycle**, **W-Cycle**, or **F-Cycle**.)

AMG Method

contains the drop-down list to choose between two AMG solvers: aggregative or selective. See Setting the AMG Method and the Stabilization Method (p. 1578) for details.

Aggregative

enables aggregative AMG solver.

Selective

enables selective AMG solver. The selective AMG solver is available only for scalar equations, and is not available in parallel ANSYS Fluent.

Stabilization Method

contains the drop-down list to choose the stabilization method.

BCGSTAB

enables bi-conjugate gradient stabilized method.

RPM

enables the recursive projection method. RPM stabilization is mainly used in conjunction with the coupled pressure-based solver.

CG

enables the conjugate gradient method. CG stabilization is mainly used in conjunction with the segregated pressure-based solver.

Algebraic Multigrid Controls

contains parameters related to the algebraic multigrid solver. See Algebraic Multigrid (AMG) in the Theory Guide and Modifying Algebraic Multigrid Parameters (p. 1670) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scalar and Coupled Parameters
contain parameters that you can set, If you are using the density-based explicit solver or the pressure-based solver with any of the segregated schemes, described in Pressure-Velocity Coupling in the Theory Guide and Choosing the Pressure-Velocity Coupling Method (p. 1561), you will only set **Scalar Parameters**. If you are using the density-based implicit or the pressure-based coupled scheme, described in Coupled Algorithm, then you can set the **Coupled Parameters**.

Fixed Cycle Parameters
contains parameters that control the V, W, and F cycles. You can set the number of **Pre-Sweeps** and **Post-Sweeps**, and the **Max Cycles**. Normally one post-sweep is performed and no pre-sweeps are done. See Fixed Cycle Parameters (p. 1580) for details about using the items below.

Pre-Sweeps
sets the number of sweeps to perform before moving to a coarser level.

Post-Sweeps
sets the number of sweeps to perform after coarser level corrections have been applied.

Max Cycles
sets the maximum number of V, W, or F cycles to be performed. The multigrid solver will continue to solve the set of equations until either the maximum number of cycles has been performed, or the **Termination** criteria are satisfied.

Coarsening Parameters
contains parameters that control the grouping of equations in the algebraic multigrid algorithm. See Coarsening Parameters (p. 1580) for details

Max Coarse Levels
is the maximum number of coarse levels that will be built by the multigrid solver. Sets of coarser simultaneous equations are built until the maximum number of levels has been created, or the coarsest level has only 3 equations. Each level has about half as many unknowns as the previous level, so coarsening until there are only a few nodes left will require about as much total coarse-level coefficient storage as was required on the fine mesh. Reducing the maximum coarse levels will reduce the memory requirements, but may require more iterations to achieve a converged solution. Setting **Max Coarse Levels** to 0 turns off the multigrid solver.

Coarsen by
controls the number of equations on each successively coarser grid level. By default, this parameter is set to 2, indicating that the number of equations on each level will be 1/2 of the number on the previous level. In general, the number of equations on each coarser grid level will be equal to $1/n$ of the number on the previous level, where n is the value set for the **Coarsen by** parameter.

Conservative Coarsening
enables the use of conservative coarsening techniques that can improve parallel performance and/or convergence for some difficult cases. This option is only available under **Coupled Parameters**.

Laplace Coarsening
enables the use of Laplace coefficients when grouping cells for coarsening.

Smoother Type
consist of two types:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Gauss-Seidel
is the simplest smoother type and is recommended when using the pressure-based segregated solver.

ILU
is more CPU intensive, but has better smoothing properties for block-coupled systems such as the pressure-based coupled solver and the density-based implicit solver.

Flexible Cycle Parameters
contains parameters that control the flexible multigrid cycle.

Sweeps
specifies the number of times to apply the smoothing method each time a relaxation is performed.

Max Fine Relaxations
sets the maximum number of relaxations to be performed on the Level 1 grid (fine grid level). This parameter eliminates the possibility that the Gauss-Seidel solver will get "stuck" on the fine grid level, unable to reduce the residuals by the fraction (α) required by the **Termination** criteria.

Max Coarse Relaxations
sets the maximum number of relaxations to be performed on each grid level above Level 1 (that is, the coarse grid levels). This parameter eliminates the possibility that the Gauss-Seidel solver will get "stuck" on a coarse grid level, unable to reduce the residuals on that level by the fraction (α) required by the **Termination** criteria. If the iterative solution on a given grid level is unable to meet the accuracy constraint of the **Termination** criteria, the correction equation will be deemed "converged" when this maximum number of relaxations on that grid level has been performed.

Options
contains additional multigrid parameters.

Verbosity
controls the amount of information that is printed out by the multigrid solver for monitoring purposes. See Setting the Verbosity (p. 1582) for details

FAS Multigrid Controls
contains parameters related to the FAS multigrid solver. See Full-Approximation Storage (FAS) Multigrid in the Theory Guide and Setting FAS Multigrid Parameters (p. 1583) for details. As noted in the title of this dialog box section, the FAS multigrid solver is used only for the **Flow** equations (pressure, momentum, and energy).

This section of the dialog box appears only when the density-based explicit solver is used.

Fixed Cycle Parameters
contains parameters that control the V, W, and F cycles of the FAS multigrid solver.

Pre-Sweeps
sets the number of iterations of the multi-stage solver to be performed on a given grid level before proceeding to a coarser grid level (the value of β_1 described in Multigrid Cycles in the Theory Guide). Typically, this is set to 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Post-Sweeps
sets the number of multigrid cycles to be performed on a given grid level before proceeding back up to the finer grid level (the value of β_2 described in Multigrid Cycles in the Theory Guide). A value of 1 results in V-cycle multigrid, and a value of 2 results in W-cycle multigrid.

Coarsening Parameters
contains parameters that control the grouping of cells in the FAS multigrid algorithm.

Max Coarse Levels
sets the maximum number of grid levels to be used in the multigrid process. A value of 0 disables multigrid (no coarse grid levels). If the coarse grids do not already exist, they are created automatically when you start iterating; you cannot create them by clicking the **OK** button. See Turning On FAS Multigrid (p. 1575) for details.

Coarsen by
controls the number of cells in each successively coarser grid level. By default, this parameter is set to 2, indicating that the number of cells on each level will be 1/2 of the number on the previous level. In general, the number of cells on each coarser grid level will be equal to 1/ n of the number on the previous level, where n is the value set for the **Coarsen by** parameter.

Relaxation Factors
are provided to moderate and stabilize the multigrid corrections.

Courant Number Reduction
sets the factor by which to reduce the Courant number for coarse grid levels (that is, every level except the finest). Some reduction of time step (such as the default 0.9) is typically required because the stability limit cannot be determined as precisely on the irregularly shaped coarser grid cells.

Correction Reduction
sets the factor by which to reduce the magnitude of the multigrid corrections transferred from one level to the next finer level. A typical value with $\beta_1 = 1$ is 0.6. If two **Pre-Sweeps** and two **Post-Sweeps** are performed, this value can often be increased to 1.0 (that is, full correction transfer).

Species Correction Reduction
sets the factor by which to reduce the magnitude of the species corrections to stabilize the multigrid calculation. This item appears only when species transport is being modeled.

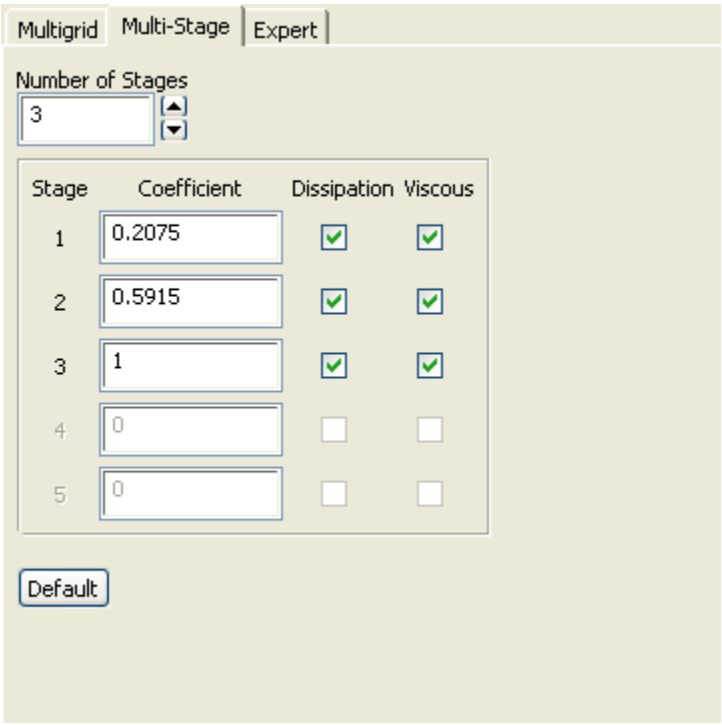
Correction Smoothing
sets the correction smoothing factor used to interpolate corrections from a coarser grid to a finer grid. For multigrid on structured meshes, corrections can be interpolated up to a finer mesh "smoothly" by using, for example, tri-linear interpolation. For unstructured meshes there is no analogous simple, algebraic procedure that can be used to interpolate without introducing substantial high frequency "noise". Instead, the corrections are first interpolated, and then subjected to a smoothing pass. The default **Correction Smoothing** value of 0.5 should be acceptable for all cases; you should not need to change it.

Options
contains additional multigrid parameters.

Verbosity
controls the amount of information that is printed out by the multigrid solver for monitoring purposes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Multi-Stage
tab allows you to set parameters that govern the operation of the multi-stage solver. It is available only when the density-based explicit solver is used. See Changing the Multi-Stage Scheme (p. 1588) for details about the items below.



Controls

Number of Stages
is the number of stages used in the multi-stage scheme. The default scheme is a 3-stage scheme with coefficients of 0.2075, 0.5915, and 1.0 for the first through third stages, respectively. Although the dialog box limits the maximum number of stages to five, you can define a scheme with an arbitrary number of stages with the `solve/set/multi-stage` text command.

Stage
labels the stage to which the parameters in the other columns apply.

Coefficient
sets the multi-stage coefficient for each stage. Coefficients should be greater than zero and less than one. The final stage should always have a coefficient of 1.

Dissipation
sets the stages for which artificial dissipation is evaluated. If a **Dissipation** box is selected for a particular stage, artificial dissipation will be updated on that stage. If not selected, artificial dissipation will remain "frozen" at the value of the previous stage.

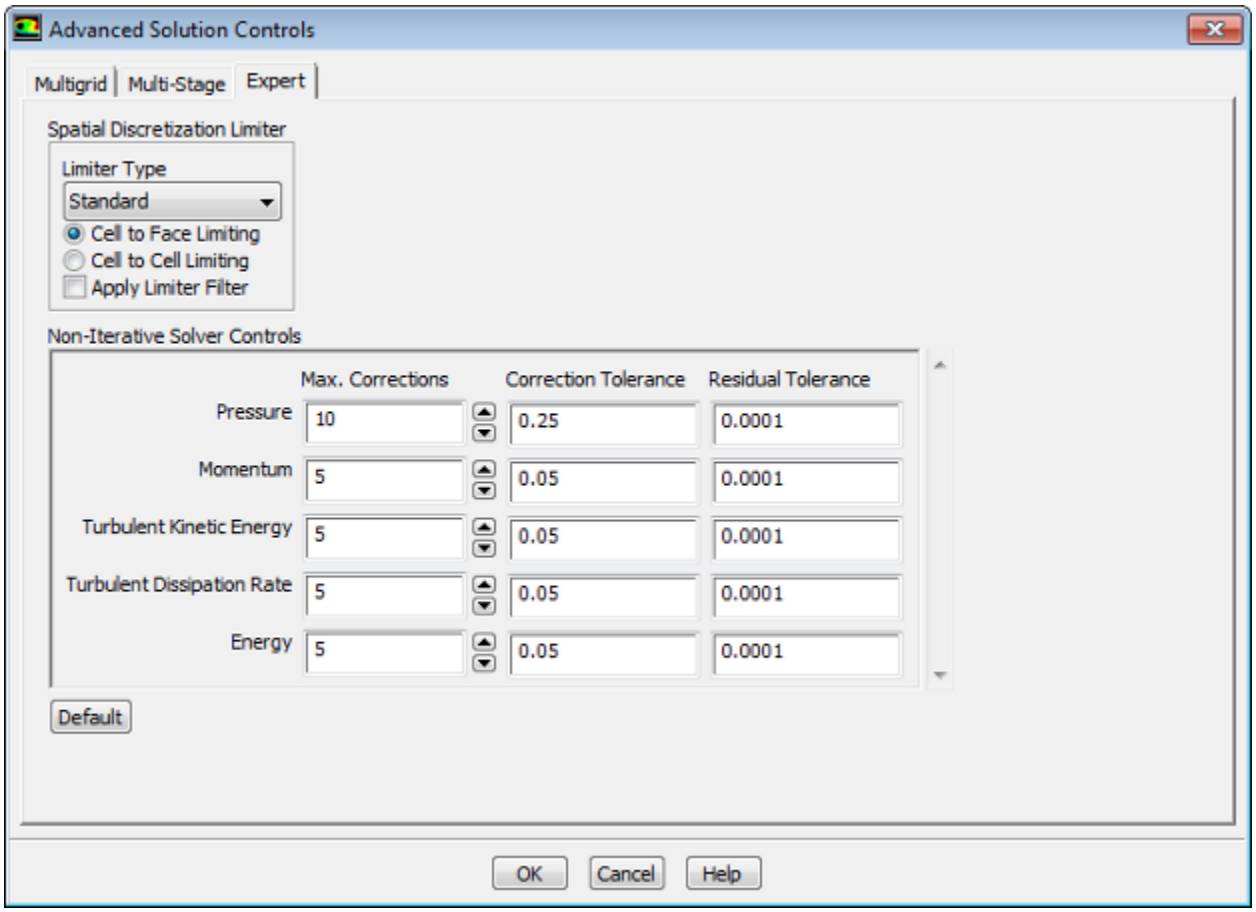
Viscous
sets the stages for which viscous stresses are evaluated. If a **Viscous** box is selected for a particular stage, viscous stresses will be updated on that stage. If not selected, viscous stresses will remain "frozen" at the value of the previous stage. Viscous stresses should always be computed on the first stage, and successive evaluations will increase the "robustness" of the solution process, but will also increase the expense (that is, increase the CPU time per iteration). For steady problems, the final solution is independent of the stages on which viscous stresses are updated.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default
sets the fields to their default values, as assigned by ANSYS Fluent. After execution, the **Default** button becomes the **Reset** button.

Reset
resets the fields to their most recently saved values (that is, the values before **Default** was selected). After execution, the **Reset** button becomes the **Default** button.

Expert
tab contains specialized parameters for limiting spatial discretization, as well as controls for the non-iterative solver.



Controls

Spatial Discretization Limiter
contains controls for limiting the spatial discretization. See Selecting Gradient Limiters (p. 1590) for more information about limiters.

Limiter Type
selects the type of limiter applied to the spatial discretization: **Standard**, **Multidimensional**, or **Differentiable**.

Cell to Face Limiting
is where the limited value of the reconstruction gradient is determined at the cell face centers. This is the default method.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cell to Cell Limiting
is where the limited value of the reconstruction gradient is determined along a scaled line between two adjacent cell centroids. On an orthogonal mesh (or when the cell-to-cell direction is parallel to face area direction), this method becomes equivalent to the default cell to face method. For smooth field variation, cell to cell limiting may provide less numerical dissipation on meshes with skewed cells.

Apply Limiter Filter
enables the limiter filter. The limiter filter is only available with the **Standard** and **Differentiable** limiter types.

Pseudo Transient Method Usage
allows you to select and modify the parameters for each individual equation. See Setting Solution Controls for the Pseudo Transient Method (p. 1604) for details.

On/Off
enables/disables the equation-specific steady state solution method for a particular equation.

Under-Relaxation Factor
allows you to use the standard steady state method by turning off pseudo transient for that particular equation. Specify the corresponding under-relaxation factor to be employed with a particular equation.

Time Scale Factor
allows you to specify a factor that scales the pseudo time step employed for the flow equations specified in the **Run Calculation** task page. A time scale factor other than 1.0 (default) allows the use of an equation specific time step in lieu of using a uniform global pseudo time step.

Non-Iterative Solver Controls
contain parameters that control the sub-iterations for the individual equations. See Time-Advancement Algorithm in the Theory Guide for details.

Max. Corrections
provide control over the maximum number of sub-iterations for each individual equation.

Correction Tolerance
defines the overall accuracy.

Residual Tolerance
controls the solution of the linear equations.

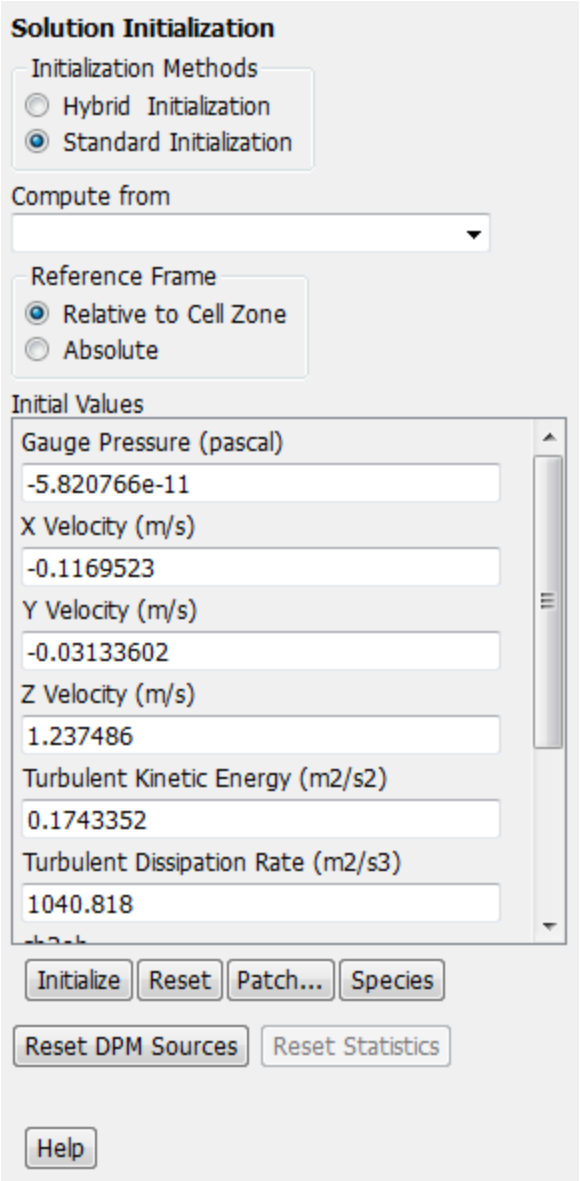
Default
sets the fields to their default values, as assigned by ANSYS Fluent. After execution, the **Default** button becomes the **Reset** button.

Reset
resets the fields to their most recently saved values (that is, the values before **Default** was selected). After execution, the **Reset** button becomes the **Default** button.

37.15. Solution Initialization Task Page

The **Solution Initialization** task page allows you to define values for flow variables and initialize the flow field to these values. See for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Initialization Method

allows you to choose between **Hybrid Initialization** and **Standard Initialization**.

Hybrid Initialization

is a collection of boundary interpolation methods, where variables, such as temperature, turbulence, species fractions, volume fractions, and so on, are automatically patched based on domain averaged values or a particular interpolation recipe (see Hybrid Initialization (p. 1597)).

Standard Initialization

allows you to define values for flow variables and initialize the flow field to these values.

Compute from

is a drop-down list of zones; the default values for applicable variables will be computed from information contained in the zone that you select from this list. The computation will occur when you select the required zone, and the variable values will be displayed in **Initial Values**. You can also choose the **all-zones** item in this list to compute average values based on all zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reference Frame
indicates whether the initial velocities are absolute velocities (**Absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

Initial Values
displays the initial values of applicable variables. You can use **Compute from** to compute values from a particular zone, or you can enter values directly. For species transport cases with a single phase flow, only the boundary species that you have selected in the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)) appear in the list. You can add or remove a species using the **Select Boundary Species** dialog box that can be accessed by clicking **Species** in the **Initialization** task page.

Initialize
initializes the entire flow field to the values listed.

Reset
resets the fields to their "saved" values.

Patch...
opens the Patch Dialog Box (p. 2522).

Species
opens the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)), where you can select the boundary species to be displayed in the **Initial Values** list and in the **Patch**, **Hybrid Initialization**, and relevant boundary conditions dialog boxes. You can modify the selected boundary species list on the fly during the problem setup. This item appears for species transport cases with a single phase flow only.

Reset DPM Sources
allows you to reset the interphase sources/sinks of momentum, heat, and/or mass to zero. This item is available when you perform coupled discrete phase calculations. See Resetting the Interphase Exchange Terms (p. 1329) for details.

Reset Statistics
can be used to both initialize the flow statistics and reset the flow statistics after you have gathered some data for time statistics. This item is available when you perform unsteady calculations and have enabled the **Data Sampling for Time Statistics** option in the Run Calculation Task Page (p. 2537). See User Inputs for Time-Dependent Problems (p. 1609) for details.

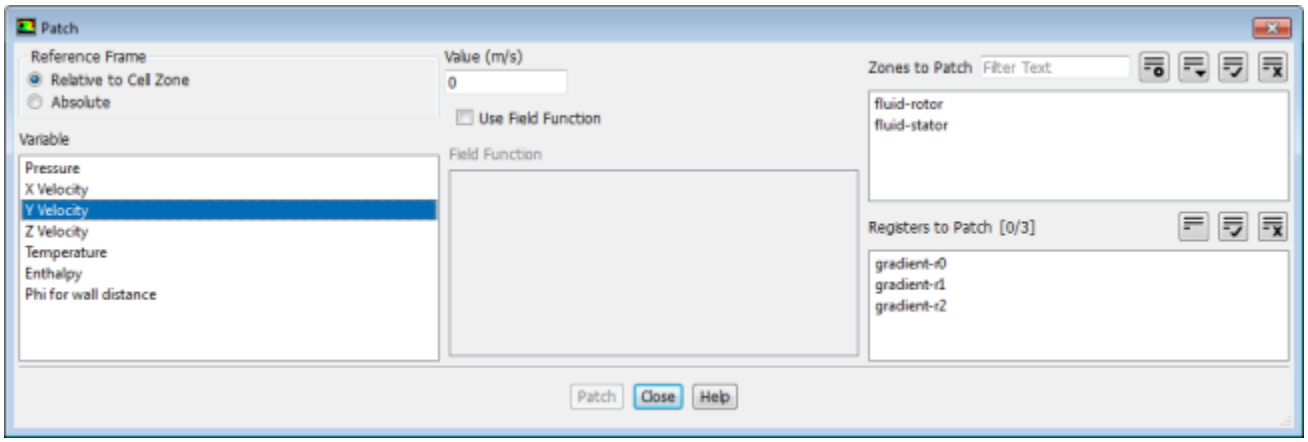
More Settings...
opens the Hybrid Initialization Dialog Box (p. 2524). This button is available only when **Hybrid Initialization** is the selected method.

For additional information, see the following sections:
37.15.1. Patch Dialog Box
37.15.2. Hybrid Initialization Dialog Box

37.15.1. Patch Dialog Box

The **Patch** dialog box allows you to patch different values of flow variables into different cells. See Patching Values in Selected Cells (p. 1593) for details about using this feature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Reference Frame

indicates whether patched velocities are absolute velocities (**Absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent. Also, this selection affects only velocities, so the options will not be available unless you have selected a velocity in the **Variable** list.

Phase

contains a list of all of the phases in the problem that you have defined. This is available when the VOF, mixture, or Eulerian multiphase model is enabled.

Variable

contains a list of flow variables from which you can choose the variable to be patched. For species transport cases with a single phase flow, only the boundary species that you have selected in the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)) appear in the list. You can add or remove a species using the **Select Boundary Species** dialog box that can be accessed by clicking **Species** in the **Initialization** task page.

Volume Fraction Patch Options

contains options that can be used when patching volume fraction for VOF and Eulerian multiphase with Multi-Fluid VOF simulations.

Patch Reconstructed Interface

applies a piecewise-linear reconstruction of the interface when patching a user-defined register and patches cells that intersect the interface with the actual volume fraction.

Volumetric Smoothing

enables smoothing of the volume fraction based on the volumetric average over the cell neighbors. After enabling volumetric smoothing, you can click Smooth to apply smoothing to the volume fraction field for all phases in the entire domain.

Smoothing Relaxation Factor

controls the degree of smoothing applied to the volume fraction field. This can be set between `0` (no smoothing) and `1` (maximum smoothing).

Value

sets a constant value to be patched for the selected **Variable**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use Field Function
enables the patching of a custom **Field Function**, rather than a constant **Value**, for the selected **Variable**. See Using Field Functions (p. 1595) for details.

Field Function
contains a list of defined custom field functions. If the **Use Field Function** option is enabled, you can patch one of these functions for the selected **Variable**. See Using Field Functions (p. 1595) for details.

Zones to Patch
contains a list of cell zones. The specified **Value** or **Field Function** for the selected **Variable** will be patched into the zones you select from this list.

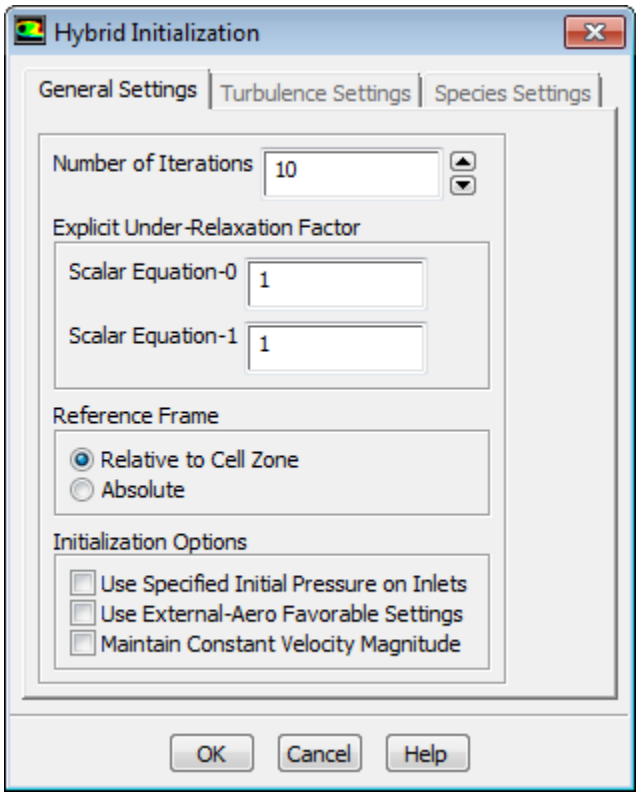
Registers to Patch
contains a list of cell registers that have been created using the adaption tools. You can patch a different value for a group of cells within a single cell zone by selecting a register containing a subset of the cells in the zone. See Using Registers (p. 1595) for details.

Patch
updates the flow-field data based on the inputs above.

Smooth
apply volumetric smoothing to the volume fraction field. This button only appears if **Volumetric Smoothing** is enabled.

37.15.2. Hybrid Initialization Dialog Box

The **Hybrid Initialization** dialog box contains a host of adjustable settings that control the **Hybrid Initialization** strategy.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

General Settings

allow you to adjust such entries as the number of iterations and under-relaxation factors.

Number of Iterations

uses a default value of 10. This is the number of iterations that will be performed while solving the Laplace equations to initialize the velocity and pressure. If the initialized velocity and pressure fields are not to your liking, you may want to increase the number of iterations and re-initialize the solution.

Explicit Under-Relaxation Factor

uses a default value of 1. This value will be used while solving the Laplace equation to initialize the velocity and pressure. If the initialized velocity and pressure fields are not to your liking, you may want to adjust the under-relaxation factor and re-initialize the solution.

Reference Frame

indicates whether the initial velocities are absolute velocities (**Absolute**) or velocities relative to the motion of each cell zone (**Relative to Cell Zone**). This selection is necessary only if your problem involves moving reference frames or sliding meshes. If there is no zone motion, both options are equivalent.

Initialization Options

allows you to include any of the three initialization options.

Use Specified Initial Pressure on Inlets

if you want the specified pressure for **Supersonic/Initialization Gauge Pressure** at the inlet boundaries to be used for solving the Laplace equation for the pressure.

Use External-Aero Favorable Settings

if you want to have the velocity potential patched with a linear value to help accelerate convergence of **Scalar Equation–0** and to obtain a better guess of the velocity field for external-aero problems.

Maintain Constant Velocity Magnitude

if you want to use the flow direction obtained from solving the velocity potential (**Scalar Equation–0**), while maintaining a constant velocity magnitude throughout the computational domain.

Turbulence Settings

uses by default the domain averaged values for the turbulence parameters. If you want to use variable turbulence parameters you can deselect the **Average Turbulent Parameters** check box. When this option is disabled, then it calculates the turbulent parameters, such as kinetic energy, dissipation energy, and so on, using local flow parameters.

Species Settings

will by default initialize secondary species with zero mass or mole fractions. If you want to specify the appropriate value for the species, you must enable **Specify Species Parameters**. Note that only the boundary species that you have selected in he **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)) appear in the list. You can add or remove a species using the **Select Boundary Species** dialog box that can be accessed by clicking **Species** in the **Initialization** task page.

37.16. Calculation Activities Task Page

The **Calculation Activities** task page allows you to set up various tasks that you can perform during the calculation, such as saving files, exporting files, creating solution animations, and command execution.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Autosave Every
allows you to set the frequency of the autosave.

Edit...
opens the Autosave Dialog Box (p. 2527).

Automatic Export
displays a list of available export objects that will be executed during the calculations. This list and its associated buttons are only available for transient flow calculations.

Create
provides a drop-down list that contains options for creating export objects. Two options are available: the **Solution Data Export** option opens the Automatic Export Dialog Box (p. 2530); the **Particle History Data Export** option opens the Automatic Particle History Data Export Dialog Box (p. 2533).

Edit...
opens the appropriate dialog box for the selected item in the **Automatic Export** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Delete
removes the selected item from the **Automatic Export** list.

Execute Commands
lists available commands to be executed during the calculations.

Create/Edit...
opens the Execute Commands Dialog Box (p. 2535).

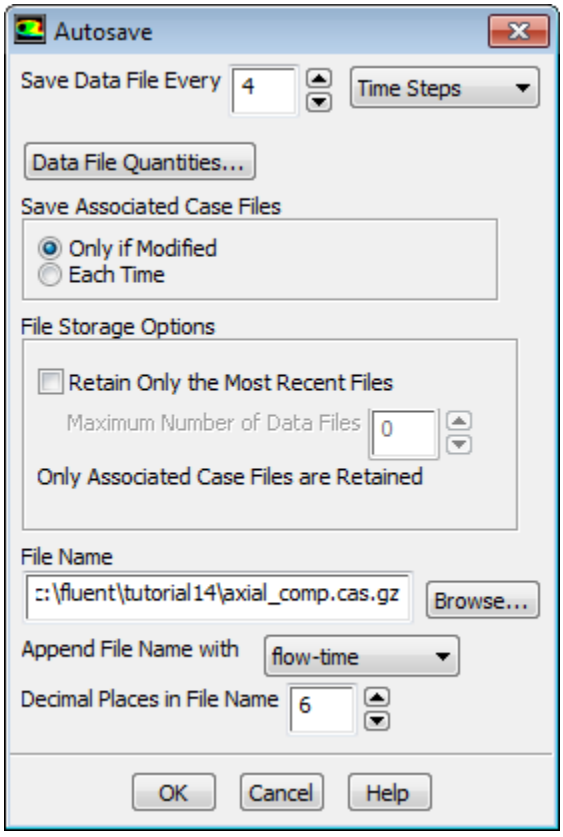
Automatically Initialize Solution and Modify Case
allows you to automatically have your solution initialized and your case file modified.

Edit...
opens the Automatic Solution Initialization and Case Modification Dialog Box (p. 2536). This button is only available when the **Automatically Initialize Solution and Modify Case** option is enabled.

For additional information, see the following sections:
37.16.1. Autosave Dialog Box
37.16.2. Data File Quantities Dialog Box
37.16.3. Automatic Export Dialog Box
37.16.4. Automatic Particle History Data Export Dialog Box
37.16.5. Execute Commands Dialog Box
37.16.6. Define Macro Dialog Box
37.16.7. Automatic Solution Initialization and Case Modification Dialog Box

37.16.1. Autosave Dialog Box

The **Autosave** dialog box allows you to specify automatic saving of case and data files at specified intervals during a calculation. See Automatic Saving of Case and Data Files (p. 48) for details.



Controls

Save Data File Every
specifies the frequency with which data files are saved. For steady flows you will specify the frequency in iterations, while for unsteady flows you will specify it in time steps (unless you are using the explicit time stepping formulation, in which case you will specify the frequency in iterations or if you are running an in-cylinder simulation you can specify the frequency in crank angles). The default value is set to zero, indicating that no automatic saving is performed.

When the Data File is saved, Save the Case
gives you the choice to save the case file only if it is modified or each time that the data file is saved.

If Modified During the Calculation or Manually
will result in ANSYS Fluent saving a case file whether you make a manual change, or if ANSYS Fluent makes a change to the code internally during the calculation.

Each Time
allows you to save the case file every time the data file is saved.

Retain Only the Most Recent Files
allows you to restrict the number of files saved by ANSYS Fluent if you have limited disk space. When this option is enabled, you can enter the appropriate value in the **Maximum Number of Data Files** field.

Only the associated case files are retained when using this option.

Important

When the **Retain Only the Most Recent Files** option is selected, the solution history currently in memory will be discarded and the solution history reset.

Data File Quantities
opens the Data File Quantities Dialog Box (p. 2529) where you can specify which quantities you want to automatically save to a data file for postprocessing.

Maximum Number of Data Files
specifies the maximum number of data files that can be saved at any instance. If you have constraints on the disk space, you can restrict the number of files to be saved using this field. After saving the specified number of files, ANSYS Fluent will overwrite the earliest existing file. The default value for this field is zero, which saves all the files.

File Name
specifies the root name for the files that are saved. The iteration or time-step number and an appropriate suffix (`.cas` or `.dat`) will be added to the specified root name. If the specified **File Name** ends in `.gz` or `.Z`, appropriate file compression will be performed. (See Reading and Writing Compressed Files (p. 41) for details about file compression.)

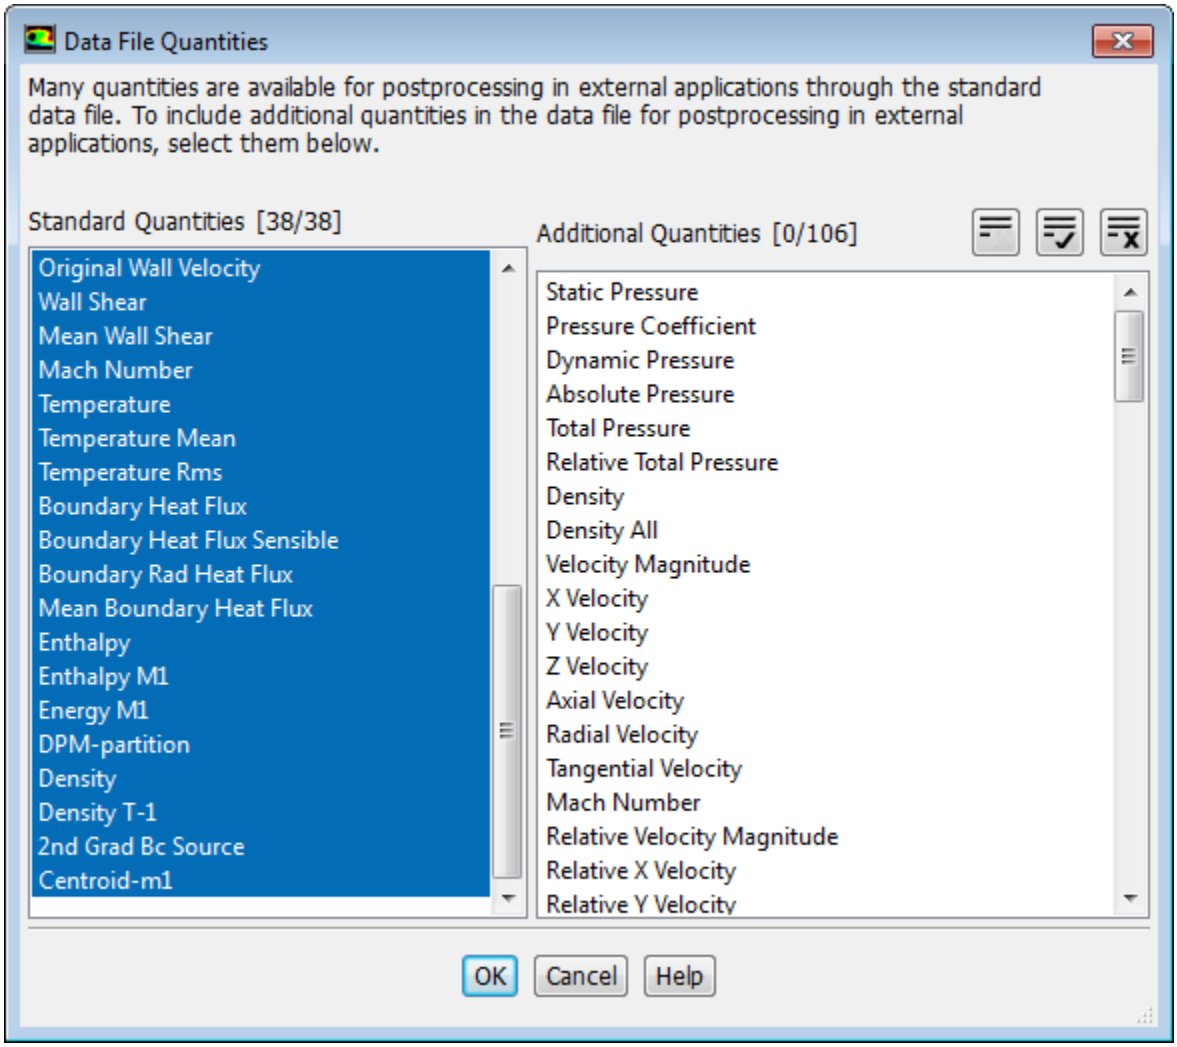
Append File Name with
allows you to select **flow-time**, **time-step**, or **crank-angle** to be appended to the file name. This option is available only for unsteady-state calculations (only for in-cylinder calculations in the case of **crank-angle**). The default selection is **flow-time**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Decimal Places in File Name
allows you to specify the number of decimal digits in the file name. This option is available only when **flow-time** or **crank-angle** is selected in the **Append File Name with** drop-down list. The default value for this field is set to 6.

37.16.2. Data File Quantities Dialog Box

The **Data File Quantities** dialog box allows you to specify various quantities for postprocessing. See Setting Data File Quantities (p. 107) for details.



Controls

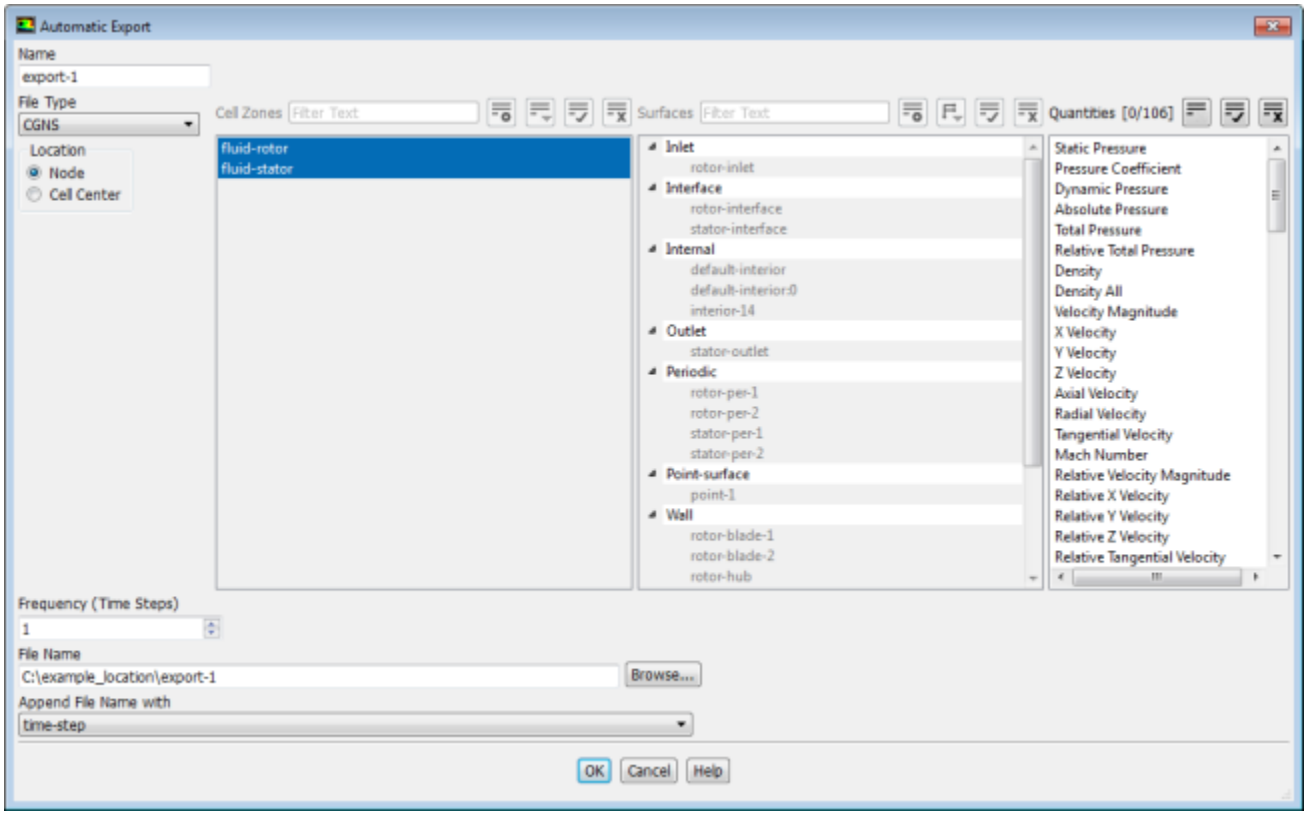
Standard Quantities
contains a listing of standard postprocessing quantities (for example, density, Mach number, temperature, and so on).

Additional Quantities
contains a listing of additional postprocessing quantities that are derived from the standard quantities (for example, standard pressure, velocity magnitude, and so on).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.16.3. Automatic Export Dialog Box

The **Automatic Export** dialog box allows you to create an automatic export definition for solution data. See Creating Automatic Export Definitions for Solution Data (p. 87) for details.



Controls

Name
specifies the name of the export definition.

File Type
contains a drop-down list of file types, which control the output file format that will be written.

ABAQUS
allows you to specify the surface(s) and optional loads, based on the kind of finite element analysis selected, to be exported to an ABAQUS file (extension `.inp`).

ASCII
allows you to specify the surface(s), scalars, location from which the values of scalar functions are to be taken, and the delimiter separating the fields, to be exported to an ASCII file.

AVS
allows you to specify the scalars you want to write to be exported to an AVS file.

CFD-Post Compatible
allows you to specify the scalars you want to write, the cell zones from which the values of scalar functions are to be taken, the file format, and whether case files are written with every `.cdat` file, as part of the exporting of files that are compatible with the CFD-Post application (that is, `.cdat` and `.cst` files).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CGNS
allows you to specify the scalars you want to write and the location from which the values of scalar functions are to be taken, to be exported to a CGNS file (extension `.cgns`).

Data Explorer
allows you to specify the surface(s) and the scalars you want to write to be exported to a Data Explorer file (extension `.dx`).

EnSight Case Gold
allows you to specify the scalars you want to write, the cell zones, interior zone surfaces, and location in the cell from which the values of scalar functions are to be taken, and the file format, to be exported to an EnSight file (extension `.geo`, `.vel`, `.scl1`, or `.encas`).

FAST
allows you to specify the scalars you want to write, to be exported as a grid file (Plot3D format), a velocity file, and a scalar file. This option is available only for a triangular or tetrahedral mesh.

FAST Solution
allows you to export a single file containing density, velocity, and total energy data. This option is available only for a triangular or tetrahedral mesh.

Fieldview Unstructured
allows you to specify the scalars you want to write and the cell zones from which the values of scalar functions are to be taken, to be exported to a FIELDVIEW binary file (extension `.fvuns`) and a regions file (extension `.fvuns.fvreg`).

I-deas Universal
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to an I-deas Universal file.

Mechanical APDL Input
allows you to specify the surface(s) and optional loads, based on the kind of finite element analysis selected, to be exported to a Mechanical APDL Input file (extension `.cdb`).

NASTRAN
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to a NASTRAN file (extension `.bdf`).

PATRAN
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to a PATRAN neutral file (extension `.out`).

RadTherm
allows you to specify the surface(s) for which you want to write data and the method of writing the heat transfer coefficient, to be exported to a PATRAN neutral file (extension `.neu`). This option is available only when the **Energy Equation** is enabled.

Tecplot
allows you to specify the surface(s) and the scalars you want to write, to be exported to a Tecplot file.

Cell Zones
specifies the cell zones for which data is to be written for a CFD-Post compatible, EnSight, or FIELDVIEW file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surfaces
specifies the surfaces for which data is to be written for an ABAQUS, ASCII, Data Explorer, I-deas Universal, Mechanical APDL Input, NASTRAN, PATRAN, RadTherm, or Tecplot file.

Quantities
specifies valid quantities for output. The attributes of the list are modified based on the active file type. The list may be a single-selection or a multiple-selection list or it may be disabled, depending on the selected **File Type**.

Analysis (for ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN formats)
specifies the finite element analysis intended.

Structural
specifies structural analysis and allows you to select the **Structural Loads** to be written.

Thermal
specifies thermal analysis and allows you to select the **Thermal Loads** to be written.

Structural Loads
contains optional structural loads that can be written to ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN files. This option is available only when **Structural** analysis is selected.

Force
enables force to be written as a load for a structural analysis.

Pressure
enables pressure to be written as a load for a structural analysis.

Temperature
enables temperature to be written as a load for a structural analysis. This option is available only when the **Energy Equation** is enabled.

Thermal Loads
contains optional thermal loads that can be written to ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN files. This option is available only when **Thermal** analysis is selected.

Temperature
enables temperature to be written as a load for a thermal analysis.

Heat Flux
enables heat flux to be written as a load for a thermal analysis.

Heat Trans Coeff
enables heat transfer coefficient to be written as a load for a thermal analysis.

Location (for ASCII, CGNS, and EnSight Case Gold formats)
specifies the location from which the values of scalar functions are to be taken.

Node
specifies that data values at the node points are to be exported.

Cell Center
specifies that data values from the cell centers are to be exported.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Format (for CFD-Post Compatible and EnSight Case Gold)
specifies the file format.

Binary
specifies the file format as binary.

ASCII
specifies the file format as ASCII.

Heat Transfer Coefficient (for RadTherm format only)
specifies the basis for the heat transfer coefficient exported.

Flux Based
specifies the flux based method for writing the heat transfer coefficient.

Wall Function
specifies the wall function based method for writing the heat transfer coefficient.

Write Case File Every Time (for CFD-Post Compatible)
specifies whether a case file is written with every `.cdat` file, or if case files are written based on the settings specified by the `file/transient-export/settings/cfd-post-compatible` text command.

Frequency (Time Steps)
specifies the frequency for appending the data during the solution process.

File Name
specifies the root name for the files to be saved.

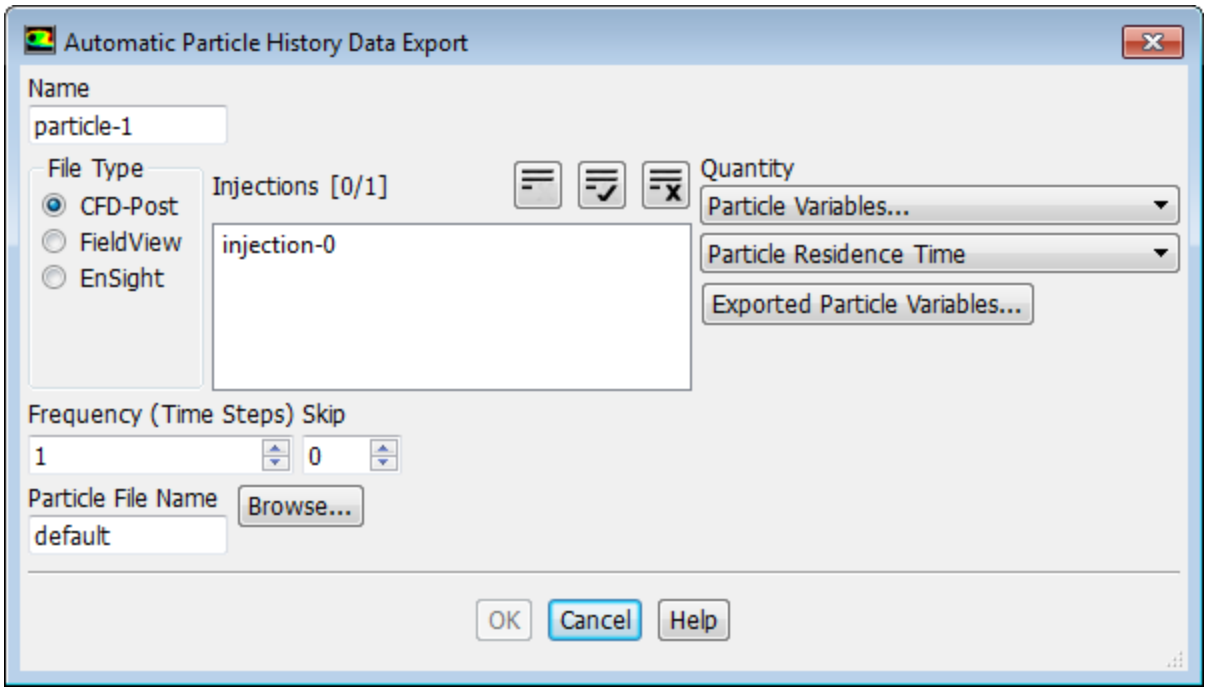
Append File Name with
allows you to select **flow-time** or **time-step** to be appended to the file name.

Decimal Places in File Name
allows you to specify the number of decimal digits in the file name. This option is available only when **flow-time** is selected in the **Append File Name with** drop-down list. The default value for this field is set to 6.

37.16.4. Automatic Particle History Data Export Dialog Box

The **Automatic Particle History Data Export** dialog box allows you to create an automatic particle history export definition for solution data. See Creating Automatic Export Definitions for Transient Particle History Data (p. 89) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
specifies the name of the particle history export definition.

File Type
specifies the type of the file you want to write.

CFD-Post
allows you to write the file in CFD-Post particle tracks format, which can be read in **CFD-Post**.

FieldView
allows you to write the file in **FIELDVIEW** format, which can be read in **FIELDVIEW**.

EnSight
allows you to write the file in **EnSight** format.

Injections
allows you to select the required injection from the list of predefined injections.

Quantity
contains the list of variables for which you can export the particle data.

Skip
allows you to "thin" or "sample" the number of particles that are exported.

Frequency (Time Steps) or (DPM Iterations)
specifies the frequency of particle time steps that are used for saving the export file.

Separate Files for Each Time Step
allows you to have separate exported data files for each time step. Available only when **EnSight** is selected as the **File Type**.

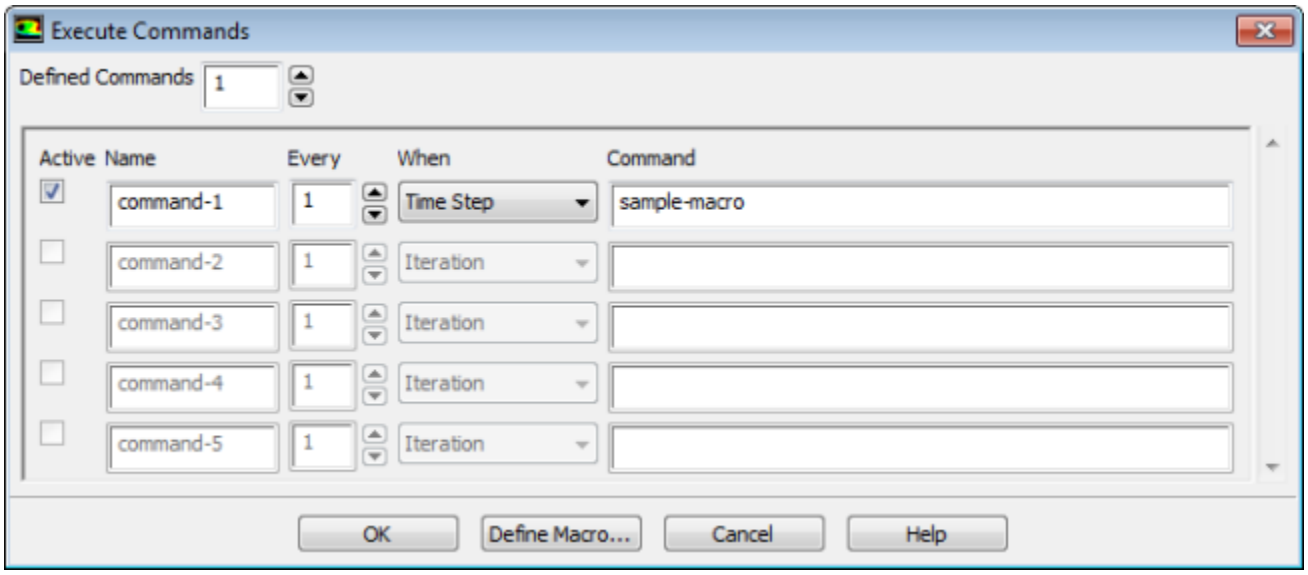
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Particle File Name
allows you to specify the file name/directory for the exported data, using the **Browse...** button.

Ensight Encas File Name
is the file name you will specify if you selected **EnSight** under **File Type**. Use the **Browse...** button to select the `.encas` file that was created when you exported the file with the **File/Export...** ribbon tab option.

37.16.5. Execute Commands Dialog Box

The **Execute Commands** dialog box allows you to define commands to be executed during the calculation. See Executing Commands During the Calculation (p. 1638) for details about using this feature.



Controls

Defined Commands
sets the total number of monitor commands to be defined.

Active
activates/deactivates the execution of each command.

Name
specifies a name for each command.

Every, When
indicate how often the command is to be executed. You can enter the interval under **Every** and select **Iteration** or **Time Step** under **When**. (**Time Step** is a valid choice only if you are calculating unsteady flow.)

Command
specifies the command to be executed. You can enter text commands or the name of a command macro that you have defined in the Define Macro Dialog Box (p. 2536).

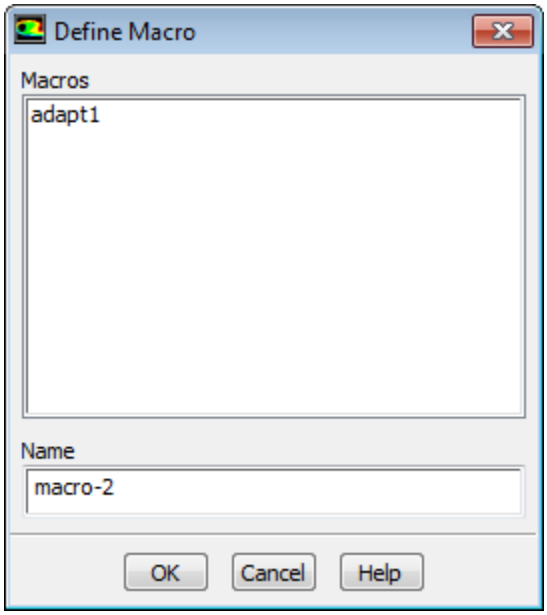
Define Macro...
opens the Define Macro Dialog Box (p. 2536), in which you can define command macros.

End Macro
ends the definition of a macro. (This button will replace the **Define Macro...** button when you click **OK** in the **Define Macro** dialog box.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.16.6. Define Macro Dialog Box

The **Define Macro** dialog box allows you to define macros for automatic execution by the command monitor, or for interactive use by you. See Defining Macros (p. 1640) for details.



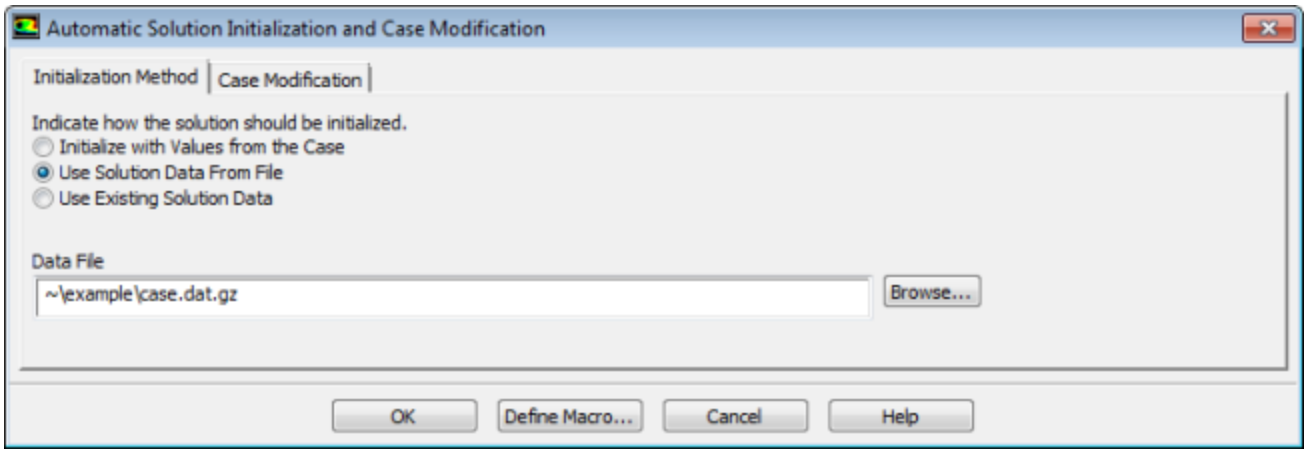
Controls

Macros
contains a selectable list of the currently-defined macros.

Name
specifies a name for the command macro.

37.16.7. Automatic Solution Initialization and Case Modification Dialog Box

The **Automatic Solution Initialization and Case Modification** dialog box allows you to specify the solution initialization method and to modify the case. See Automatic Initialization of the Solution and Case Modification (p. 1642) for details.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Initialization Method
tab contains several choices for initializing the solution.

Initialize with Values from the Case
uses the values set in the **Solution Initialization** task page.

Use Solution Data From File
requires you to read in a data file containing the desired initialization for the case.

Use Solution Data From Previous Parametric Run with Workbench
(transient cases only) requires you to select one of two methods to initialize the first run. You can **Initialize with Values from the Case**, which uses the values set in the **Solution Initialization** task page. Otherwise, you can **Use Solution Data from File**, which requires you to read in a data file containing the desired initialization for the case.

Use Existing Solution Data
is analogous to changing the values in a case and continuing the calculation. However, the iteration counter will be reset to 0 so that the modifications can be applied. Use this method when no solution data exists, similar to the first run.

Case Modification
allows you to indicate how long you would like to run with the original settings, then make any modifications to the case settings.

Defined Modifications
indicates the number of modifications for the case file.

Active
allows you to enable or disable a defined case modification.

Name
represents the name of the case modification.

Commands
represents an area where you can enter text commands.

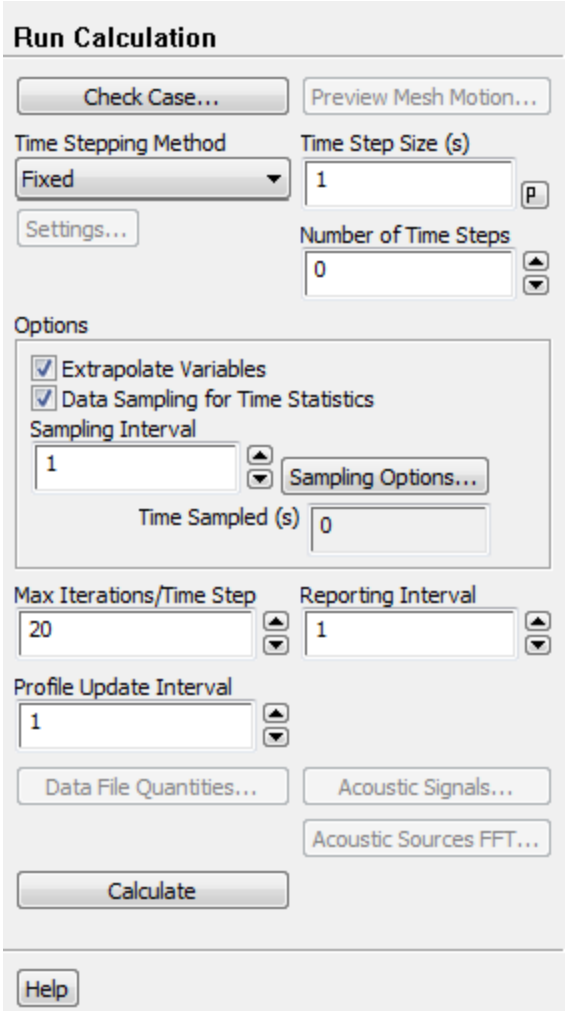
Number of Iterations/Time Steps
represents the number of iterations or time steps that you want to run defined case modification commands.

Define Macro...
opens the Define Macro Dialog Box (p. 2536), in which you can define command macros.

37.17. Run Calculation Task Page

The **Run Calculation** task page allows you to start the solver iterations. See Performing Steady-State Calculations (p. 1600) and Performing Time-Dependent Calculations (p. 1608) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Check Case...
opens the Case Check Dialog Box (p. 2543).

Preview Mesh Motion...
opens the Mesh Motion Dialog Box (p. 2500).

Pseudo Transient Options
is available for fluid and solid zones and will only appear for steady-state cases, where the pressure-based coupled solver is used. Note that the **Pseudo Transient** option must be enabled in the Solution Methods Task Page (p. 2504). For details about the available options, see Performing Pseudo Transient Calculations (p. 1601).

Number of Iterations
(for steady flow calculations) sets the number of iterations to be performed. (For unsteady calculations using the explicit unsteady formulation, this will specify the number of time steps, since each iteration will be a time step.)

Time Stepping Method
(for transient flow calculations) contains options for how the time step is determined.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fixed
selects a fixed time step, equal to the specified **Time Step Size**.

Adaptive
selects a time step that is initially equal to the specified **Time Step Size**, but gets modified by ANSYS Fluent as the calculation proceeds. See Adaptive Time Stepping (p. 1618) for details.

Variable
enables variable time stepping method. The inputs are same as for the adaptive time stepping method, with the exception of specifying a global Courant number. **Variable** is selectable when the VOF multiphase model is enabled. See Variable Time Stepping (p. 1621) for details.

Settings...
opens either the Adaptive Time Step Settings Dialog Box (p. 2544) when **Adaptive** is selected as the **Time Stepping Method**, or the Variable Time Step Settings Dialog Box (p. 2545) when **Variable** is selected as the **Time Stepping Method**.

Time Step Size(s)
(for transient flow calculations) sets the magnitude of the (physical) time step Δt.

Time Step Size for Acoustic Data Export
determines the highest frequency that the acoustic analysis reproduces. This is available when the FW-H acoustics model is enabled.

Number of Time Steps
(for transient flow calculations) sets the number of time steps to be performed.

Options
contains options related to unsteady calculations.

Extrapolate Variables
instructs ANSYS Fluent to predict the solution variable values for the next time step and then input that predicted value as an initial guess for the inner iterations of the current time step.

Data Sampling for Time Statistics
enables the sampling of data during an unsteady calculation. See User Inputs for Time-Dependent Problems (p. 1609) and Postprocessing for Time-Dependent Problems (p. 1622) for details.

Sampling Interval
allows you to specify the frequency of the **Data Sampling for Time Statistics**.

Sampling Options...
opens the Sampling Options Dialog Box (p. 2546) for the **Data Sampling for Time Statistics**.

Time sampled
displays the time period over which data has been sampled for the postprocessing of the mean and RMS values.

Solid Time Step
enables a different time step to be specified for solid zones, either user specified or automatically calculated. See Specifying a Solid Time step (p. 829) for details.

Max Iterations/Time Step
for unsteady flow calculations using an implicit unsteady formulation) sets the maximum number of iterations to be performed per time step. If the convergence criteria are met before this number of iterations

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is performed, the solution will advance to the next time step. See User Inputs for Time-Dependent Problems (p. 1609) for details.

Reporting Interval
sets the number of iterations that will pass before convergence monitors will be printed and plotted. The default is 1 (that is, reports will be updated after each iteration).

Postprocess Pollutants
results in the automatic postprocessing of pollutants during a transient simulation. This option is available when one of the pollution models is enabled.

Max Post Iterations/Time Step
sets the maximum number of postprocessing iterations to be performed per time step. This field is available when the **Postprocess Pollutants** option is enabled.

Profile Update Interval
sets the number of iterations that will pass before user-defined functions for boundary profiles will be updated.

Solution Steering
allows you to set parameters that will help ANSYS Fluent guide the calculations to a converged solution (available only for steady-state flows in the density-based implicit solver). See Solution Steering (p. 1675) for more information. When enabled, the following options are available:

Flow Type
allows you to select the flow type that best describes the flow in the solution domain. Five choices are available: **incompressible**, **subsonic**, **transonic**, **supersonic**, and **hypersonic**.

Use FMG Initialization
allows for full multigrid initialization.

First to Higher Order Blending
allows you to reduce the desired solution accuracy by selecting a blending factor less than 100%. The default setting is 100%. See First-to-Higher Order Blending in the Theory Guide for more information. The blending factor will be grayed out if **Second Order Upwind** discretization for the **Flow** equations is not selected in the **Solution Methods** task page. The solution accuracy may be reduced (typical values are 75% or 50%) if it is not possible to obtain a converged solution with the maximum second-order accuracy (blending = 100%).

More Settings...
opens the Solution Steering Dialog Box (p. 2541).

Courant Number
is a non-adjustable field displaying the current CFL number, which allows you to view it during the calculation.

Data File Quantities...
opens the Data File Quantities Dialog Box (p. 2529).

Acoustic Signals...
opens the Acoustic Signals Dialog Box (p. 2547). This button is only available when the acoustics model is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Acoustic Sources FFT...

opens the Acoustic Sources FFT Dialog Box (p. 2549). This button is only available for three-dimensional transient simulations, when the **Export Acoustic Source Data in ASD Format** option is enabled in the **Acoustics Model** dialog box.

Calculate

starts the calculations. While the calculation is in progress, a **Working** dialog box will appear. Clicking the **Cancel** button or typing **Ctrl**+**c** in the console window will interrupt the calculation at the earliest safe stopping point after the current iteration (in steady-state simulations) or the current time step (in transient simulations). The stopping point is chosen so that the field variables and solver state are updated and internally consistent. If you are running a transient simulation and want to stop the simulation immediately (before the completion of the current time step), you can type **Ctrl**+**c** a second time.

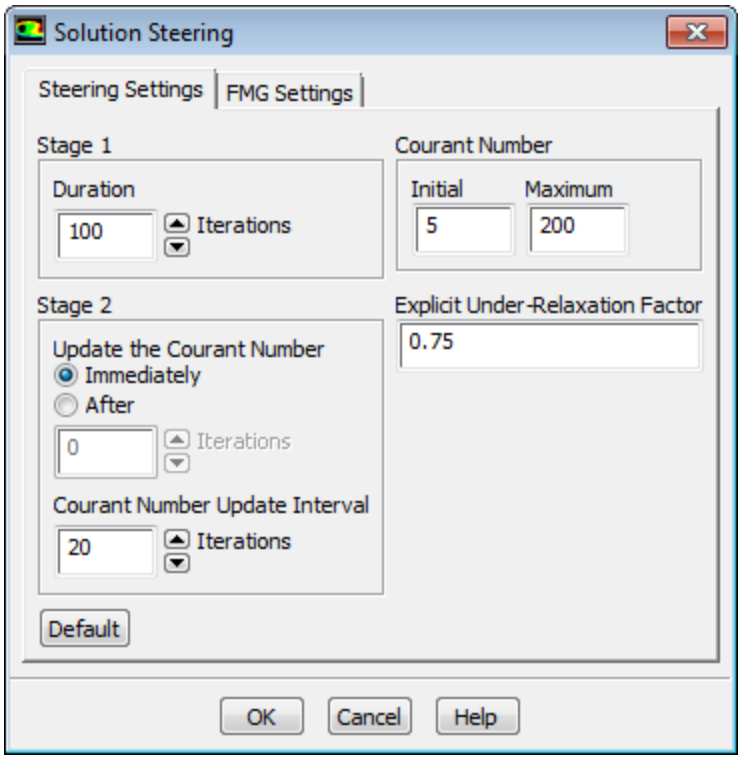
For additional information, see the following sections:

37.17.1. Solution Steering Dialog Box
37.17.2. Case Check Dialog Box
37.17.3. Adaptive Time Step Settings Dialog Box
37.17.4. Variable Time Step Settings Dialog Box
37.17.5. Sampling Options Dialog Box
37.17.6. Acoustic Signals Dialog Box
37.17.7. Acoustic Sources FFT Dialog Box

37.17.1. Solution Steering Dialog Box

The **Solution Steering** dialog box is used to set the parameters that control the solution steering strategy. Solution steering will typically perform full multigrid (FMG) initialization followed by two iterative stages (Stage 1 and Stage 2). The purpose of Stage 1 is to navigate the solution from the difficult initial phase of the solution toward convergence by insuring maximum stability. During this stage, the solution is advanced gradually from 1st-order accuracy to maximum accuracy (user specified and typically 2nd-order) at a constant low CFL value. In Stage 2, the solution is driven hard towards convergence by regular adjustments of the CFL value to insure fast convergence as well as to prevent possible divergence. In Stage 2, the residual history is monitored and analyzed through regular intervals to determine if an increase or decrease in CFL value is needed to obtain fast convergence or to prevent divergence. See Solution Steering (p. 1675) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Steering Settings
allows you to modify the steering parameters used in Stages 1 and 2.

Stage 1
allows you to set parameters relating to stage 1.

Duration
is the number of iterations in stage 1. The CFL number used during these iterations is set in the **Initial** field, in the **Courant Number** group box.

Stage 2
allows you to set parameters relating to stage 2.

Update the Courant Number
allows you to update the Courant number either **Immediately**, or **After** a specified number of iterations.

Courant Number Update Interval
defines the frequency at which the Courant number is updated.

Courant Number
allows you to set the starting (**Initial**) and maximum allowed (**Maximum**) Courant number values. The solution steering algorithm will not allow the solver to exceed the maximum Courant number, but will allow the solver to use a Courant number less than the initial Courant number if divergence in the solution has occurred.

Explicit Under-Relaxation Factor
allows the solution to be under-relaxed to improve convergence.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default
resets any changes made to the parameters to their original default values.

FMG Settings
allows you to set FMG parameters. For more information about FMG initialization, refer to Full Multigrid (FMG) Initialization (p. 1595).

Number of Multigrid Levels
allows you to set the number of multigrid levels.

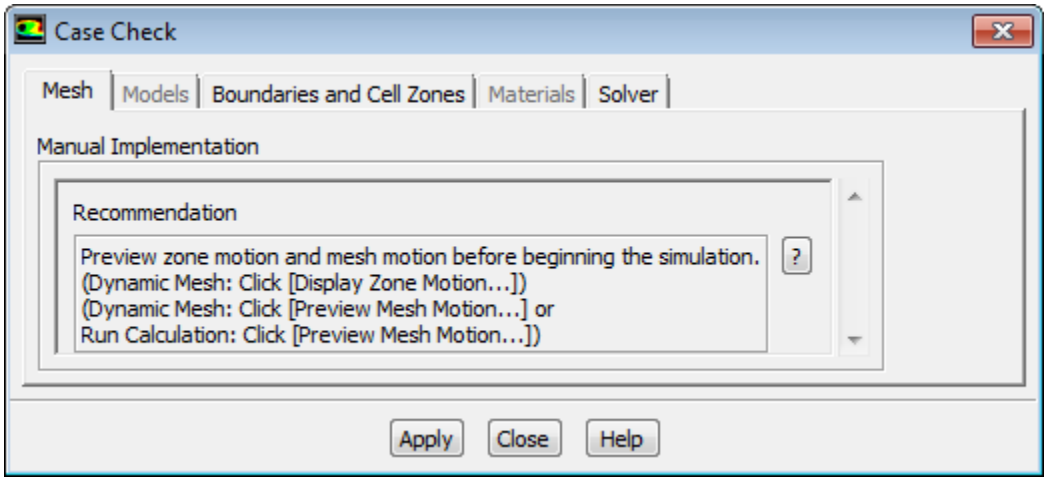
Number of Cycles
allows you to set the number of cycles for a selected level.

FMG Courant Number
allows you to set the FMG Courant number.

Default
resets any changes to the original default values.

37.17.2. Case Check Dialog Box

This function provides you with guidance and best practices when choosing case parameters and models. Your case will be checked for compliance in the mesh, models, boundary and cell zone conditions, material properties, and solver categories. Established rules are available for each category, with recommended changes to your current settings. Information about each of the recommendations is available in Checking Your Case Setup (p. 1654).



Controls

Mesh
displays recommendations, if any, relating the to the mesh used in the case. See Checking the Mesh (p. 1657) for details.

Models
displays recommendations, if any, relating the to the models used in the case. See Checking Model Selections (p. 1659) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

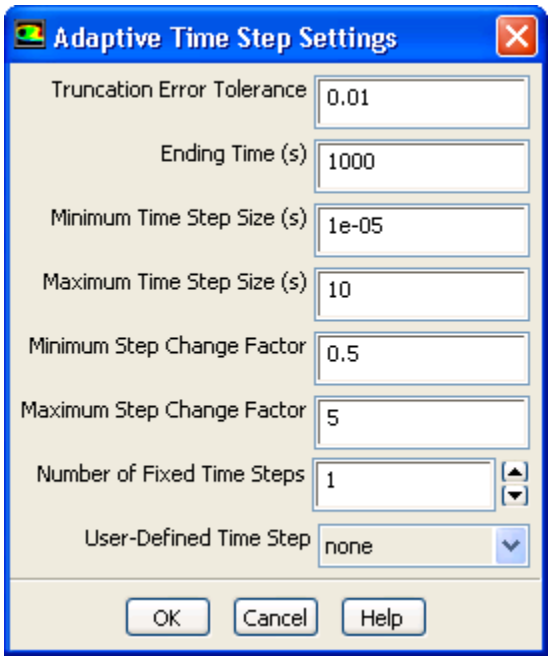
Boundaries and Cell Zones
displays recommendations, if any, relating the to the cell zones or boundaries defined in the case. See Checking Boundary and Cell Zone Conditions (p. 1661) for details.

Materials
displays recommendations, if any, relating the to the materials defined in the case. See Checking Material Properties (p. 1664) for details.

Solver
displays recommendations, if any, relating the to the solver settings used in the case. See Checking the Solver Settings (p. 1665) for details.

37.17.3. Adaptive Time Step Settings Dialog Box

The **Adaptive Time Step Settings** dialog box is used to set the parameters that control the adaptive time stepping. See Adaptive Time Stepping (p. 1618) for details.



Controls

Truncation Error Tolerance
specifies the threshold value to which the computed truncation error is compared. Increasing this value will lead to an increase in the size of the time step and a reduction in the accuracy of the solution. Decreasing it will lead to a reduction in the size of the time step and an increase in the solution accuracy, although the calculation will require more computational time. For most cases, the default value of 0.01 is acceptable.

Ending Time
specifies an ending time for the calculation. Since the ending time cannot be determined by multiplying the number of time steps by a fixed time step size, you need to specify it explicitly.

Minimum/Maximum Time Step Size
specify the upper and lower limits for the size of the time step. If the time step becomes very small, the computational expense may be too high; if the time step becomes very large, the solution accuracy may not be acceptable to you. You can set the limits that are appropriate for your simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Minimum/Maximum Step Change Factor

limit the degree to which the time step size can change at each time step. Limiting the change results in a smoother calculation of the time step size, especially when high-frequency noise is present in the solution. If the time step change factor, f, is computed as the ratio between the specified truncation error tolerance and the computed truncation error, the size of time step Δt_n is computed as follows:

- If $1 < f < f_{max}$, Δt_n is increased to meet the required tolerance.
- If $1 < f_{max} < f$, Δt_n is increased, but its maximum possible value is $f_{max} \Delta t_{n-1}$.
- If $f_{min} < f < 1$, Δt_n is unchanged.
- If $f < f_{min} < 1$, Δt_n is decreased.

Number of Fixed Time Steps

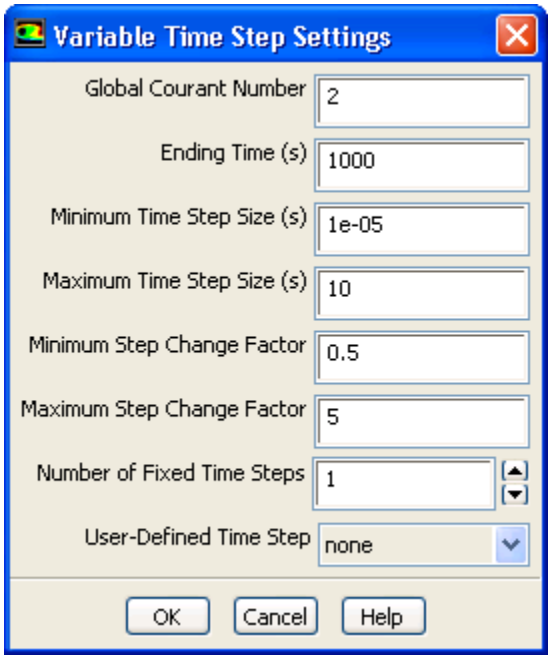
specifies the number of fixed-size time steps that should be performed before the size of the time step starts to change. The size of the fixed time step is the value specified for **Time Step Size** under **Time**.

User-Defined Time Step

contains a drop-down list of available user-defined functions.

37.17.4. Variable Time Step Settings Dialog Box

The **Variable Time Step Settings** dialog box contains parameters related to variable time stepping. See Variable Time Stepping (p. 1621) for details.



Controls

Global Courant Number

allows you to specify the Courant number. The default value for the **Global Courant number** is 2.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ending Time
specifies an ending time for the calculation. Since the ending time cannot be determined by multiplying the number of time steps by a fixed time step size, you need to specify it explicitly.

Minimum/Maximum Time Step Size
specify the upper and lower limits for the size of the time step. If the time step becomes very small, the computational expense may be too high; if the time step becomes very large, the solution accuracy may not be acceptable to you. You can set the limits that are appropriate for your simulation.

Minimum/Maximum Step Change Factor
limit the degree to which the time step size can change at each time step. Limiting the change results in a smoother calculation of the time step size, especially when high-frequency noise is present in the solution. If the time step change factor, f, is computed as the ratio between the specified truncation error tolerance and the computed truncation error, the size of time step Δt_n is computed as follows:

- If $1 < f < f_{max}$, Δt_n is increased to meet the required tolerance.
- If $1 < f_{max} < f$, Δt_n is increased, but its maximum possible value is $f_{max} \Delta t_{n-1}$.
- If $f_{min} < f < 1$, Δt_n is unchanged.
- If $f < f_{min} < 1$, Δt_n is decreased.

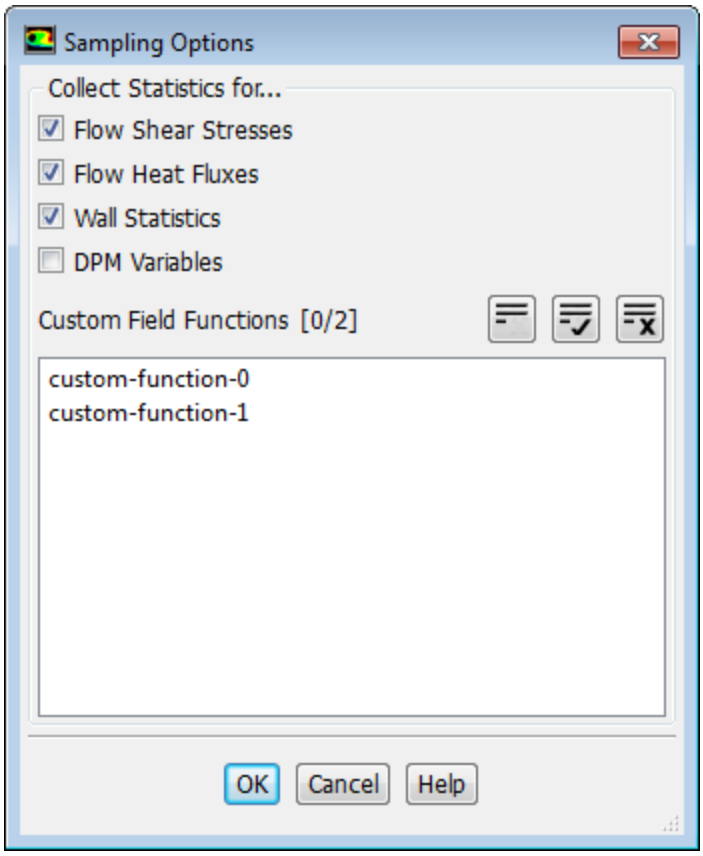
Number of Fixed Time Steps
specifies the number of fixed-size time steps that should be performed before the size of the time step starts to change. The size of the fixed time step is the value specified for **Time Step Size** under **Time**.

User-Defined Time Step
contains a drop-down list of available user-defined functions.

37.17.5. Sampling Options Dialog Box

The **Sampling Options** dialog box allows you to specify a collection of statistics for: **Flow Shear Stresses**, **Flow Heat Fluxes**, **Wall Statistics**, **DPM Variables**, and **Custom Field Functions**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Collect Statistics for...
contains options for the variables you want to be able to postprocess.

Flow Shear Stresses
allows you to enable or disable the flow shear stress statistics for postprocessing.

Flow Heat Fluxes
allows you to enable or disable the flow heat fluxes statistics for postprocessing.

Wall Statistics
allows you to enable or disable the wall statistics for postprocessing.

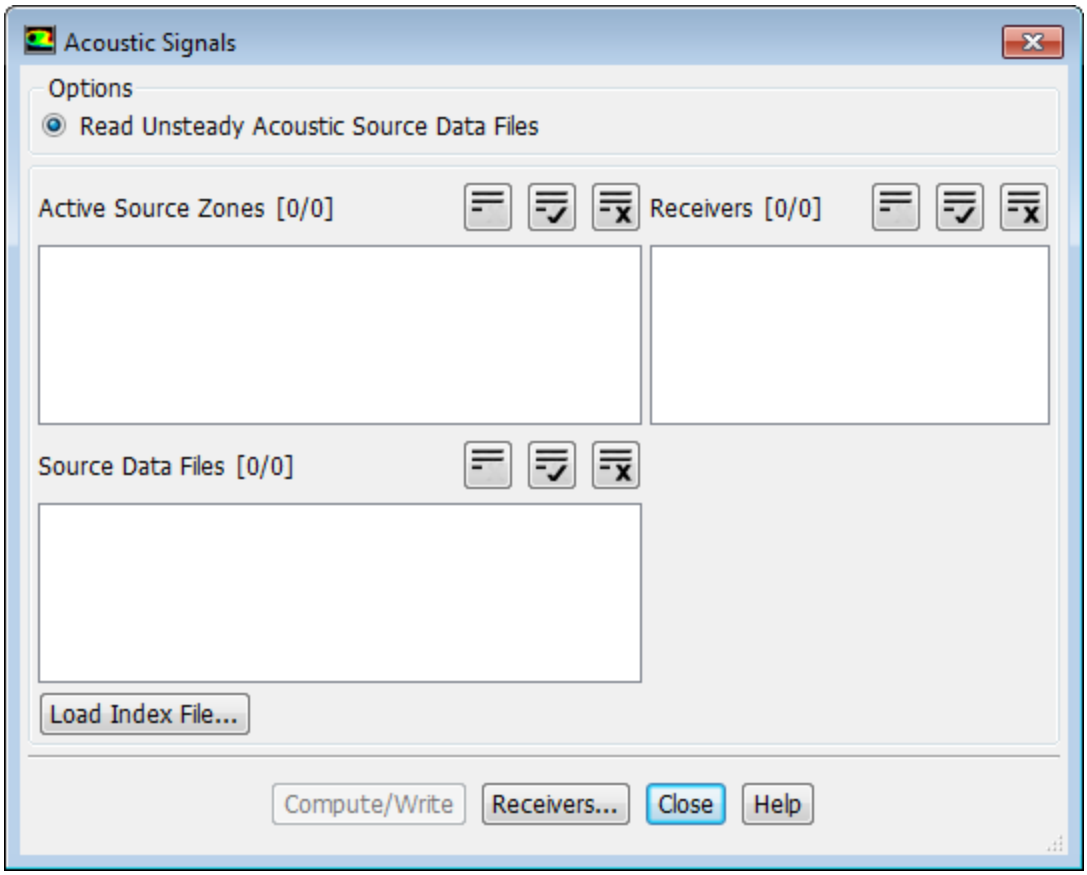
DPM Variables
allows you to enable or disable DPM variable statistics for postprocessing.

Custom Field Functions
allows you to select the previously defined custom field functions you want to be able to postprocess.

37.17.6. Acoustic Signals Dialog Box

The **Acoustic Signals** dialog box is used to compute and save the sound pressure signals. See Postprocessing the FW-H Acoustics Model Data (p. 1219) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains the options available for acoustic signal postprocessing.

Write Acoustic Signals
enables the parameters needed to write the sound pressure data to files.

Read Unsteady Acoustic Source Data Files
enables the parameters needed to compute the sound pressure signals using the source data saved to files.

Active Source Zones
contains source zones you want to include to compute sound. See Specifying Source Surfaces (p. 1214) for details.

Receivers
contains all the receivers for which you can compute sound.

Source Data Files
contains all the source data files that you can use to compute sound.

Load Index File...
opens the **Select File** dialog box, in which you can select the index file for your computation.

Write
writes the sound pressure data. This button will appear only when **Write Acoustic Signals** is selected under **Options**.

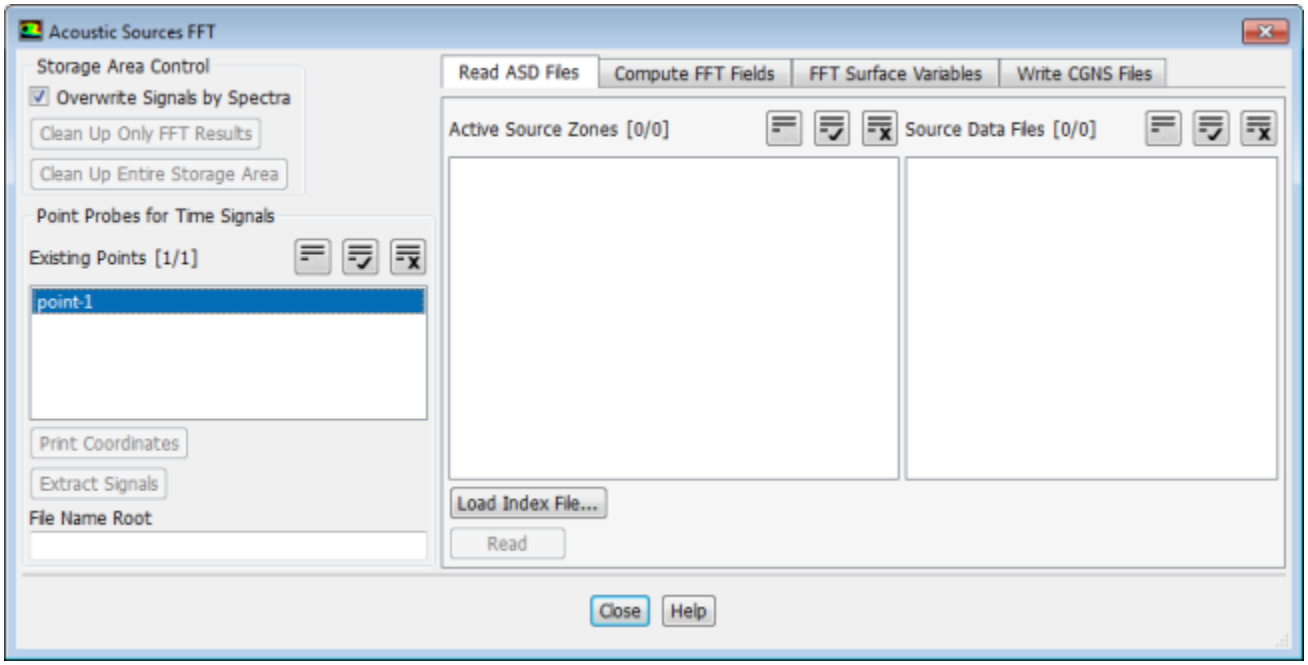
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Compute/Write
computes and saves the sound pressure data. This button will appear only when **Read Unsteady Acoustic Source Data Files** is selected under **Options**.

Receivers...
opens the Acoustic Receivers Dialog Box (p. 2293) in which you can define additional receivers.

37.17.7. Acoustic Sources FFT Dialog Box

The **Acoustic Sources FFT** dialog box allows you to: read pressure signals from the acoustic source data (ASD) files (see Writing Source Data Files (p. 1211)); compute Fourier spectra of these signals at the selected point probes and over the entire source zones; create surface variables for visualizing the spectral properties of the flow pressure signals; and write CGNS files of the spectrum data. See FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra (p. 1222) for details about the items below.



Controls

Storage Area Control
allows you to specify how memory is allocated in the "storage area" (that is, the large memory array that stores the fields of the pressure histories and the computed fields of the Fourier spectra) when you compute the FFT fields in the **Compute FFT Fields** tab.

Overwrite Signals by Spectra
specifies that the Fourier spectra displace in memory the original time signals, so that they are not kept after the FFT has been computed.

Clean Up Only FFT Results
de-allocates the storage area—so that you can re-compute the FFT without re-reading the pressure histories—and deletes all variables created through the **FFT Surface Variables** tab. This button is only available when the **Overwrite Signals by Spectra** option is disabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clean Up Entire Storage Area
de-allocates the storage area—so that you can re-read ASD files and re-compute the FFT with a clipped time range or different window function—and deletes all variables created through the **FFT Surface Variables** tab.

Point Probes for Time Signals
allows you to get information about existing point probes and create pressure history files.

Existing Points
lists all of the point probes created through the Point Surface Dialog Box (p. 2780) that are available for selection.

Print Coordinates
prints in the console the coordinates of the point probe(s) selected in the **Existing Points** selection list.

Extract Signals
creates ASCII files that contain the pressure histories of the point probe(s) selected in the **Existing Points** selection list.

File Name Root
specifies a prefix for the names of the files created by the **Extract Signals** button.

Read ASD Files
allows you to read pressure histories from the acoustic source data (ASD) files.

Active Source Zones
is a list of the face zones for which you can read acoustic source data.

Source Data Files
is a list of the ASD files you can read.

Load Index File...
updates the **Active Source Zones** and **Source Data Files** lists by loading an ASCII index file.

Read
reads the pressure signals from the selected items in the **Active Source Zones** and **Source Data Files** lists.

Compute FFT Fields
allows you to compute FFT fields from the pressure signals read through the **Read ASD Files** tab.

Sampling Data
allows you to reduce the time range of the signal data used to compute the FFT fields.

Clip Time to Range
specifies that the time range of the data sampled is reduced to be between the **Min** and **Max**.

Min
specifies the minimum value of the time range of the signal data when the **Clip Time to Range** option is enabled.

Max
specifies the maximum value of the time range of the signal data when the **Clip Time to Range** option is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Time Step
reports the size of the time step at which data was sampled.

Re-Estimate Spectral Resolution
updates the values that are displayed in the **Spectral Resolution** group box and that are used to compute the FFT fields, based on the settings in the **Sampling Data** group box.

Spectral Resolution
displays the number of samples and the expected spectrum properties for the provided signals.

Number of Samples
reports the total number of samples in the specified time range.

Samples Used for FFT
reports the number of samples that will be used for FFT (see Table 31.2: Numbers of Data Points Supported by the Prime-Factor FFT Algorithm (p. 1875)).

Frequency Min & Step
reports the expected minimum frequency in the spectrum, which is also the expected frequency step.

Frequency Max
reports the expected maximum frequency in the spectrum.

Number of Modes
reports the expected number of Fourier modes in the spectrum.

Window Function
specifies the shape of the window function used to enforce the signal's periodicity. See Windowing (p. 1873) for details. The default is the **Hanning** window.

Compute
computes the FFT fields based on the settings in the **Compute FFT Fields** tab.

FFT Surface Variables
allows you to create new Fluent variables for postprocessing using the spectrum fields computed through the **Compute FFT Fields** tab.

Modes/Frequency Bands
specifies what the created variables will characterize.

Octave Bands
specifies that the variables characterize proportional frequency bands corresponding to the standard technical octaves.

1/3 Octave Bands
specifies that the variables characterize proportional frequency bands corresponding to the standard technical thirds.

Constant Width Bands
specifies that the variables characterize user-defined equidistant frequency bands.

Set of Modes
specifies that the variables characterize the individual Fourier modes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Octave Central Frequencies
is a list of the octave central frequencies for which you can **Create** Fluent variables for postprocessing. This selection list is available when **Octave Bands** is selected from the **Modes/Frequency Bands** drop-down list.

1/3-Octave Central Frequencies
is a list of the 1/3-octave central frequencies for which you can **Create** Fluent variables for postprocessing. This selection list is available when **1/3-Octave Bands** is selected from the **Modes/Frequency Bands** drop-down list.

Frequency Min
specifies the minimum frequency of the set of modes for which you want to **Create** Fluent variables for postprocessing. This field is available when **Set of Modes** or **Constant Width Bands** is selected from the **Modes/Frequency Bands** drop-down list.

Frequency Max
specifies the maximum frequency of the set of modes for which you want to **Create** Fluent variables for postprocessing. This field is available when **Set of Modes** or **Constant Width Bands** is selected from the **Modes/Frequency Bands** drop-down list.

Number of Modes to Skip
allows you to "thin" or "sample" the modes for which you want to **Create** the Fluent variables for postprocessing. This field is available when **Set of Modes** is selected from the **Modes/Frequency Bands** drop-down list.

Band Width
specifies the width of the constant width bands, for which you want to **Create** the Fluent variables for postprocessing. This field is available when **Constant Width Bands** is selected from the **Modes/Frequency Bands** drop-down list.

Spectrum Property
displays the type of variables created according to the selected choice in the **Modes/Frequency Bands** drop-down list.

Surface Pressure Level
is displayed when frequency band is selected from the **Modes/Frequency Bands** drop-down list, in order to indicate that the created variables will be the surface pressure level (SPL) fields, in decibels.

Real and Imaginary Amplitude Parts
is displayed when **Set of Modes** is selected from the **Modes/Frequency Bands** drop-down list, in order to indicate that the created variables will be the real and imaginary parts of the complex Fourier amplitudes, with a pair of variables per specified mode.

Existing Variables
lists the processed variables that have been created by the **Create** button, and allows you to make selections for deletion using the **Remove Selected Variables** button.

Remove Selected Variables
deletes the processed variables selected in the **Existing Variables** list from the "storage area" (as described previously), so that you can analyze more than the maximum of 20 individual modes or constant width bands that are allowed to exist at any one time.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Create
creates new Fluent variables for postprocessing (based on your settings in the **FFT Surface Variables** tab), updates the **Existing Variables** selection list, and (when **Set of Modes** or **Constant Width Bands** is selected from the **Modes/Frequency Bands** drop-down list) prints information in the console.

Write CGNS Files
allows you to write CGNS files of the spectrum data.

Processed Source Zones
is a list of the zones you can export.

Frequency Series
allows you to reduce the exported spectrum data.

Reduce Frequency Series
specifies that the exported spectrum data is reduced to be between the **Min** and **Max**.

Min
specifies the minimum of the frequency range to be exported when the **Reduce Frequency Series** option is enabled.

Max
specifies the maximum of the frequency range to be exported when the **Reduce Frequency Series** option is enabled.

Number of Frequencies to Skip
allows you to "thin" or "sample" the frequencies to be exported.

Number of Frequencies per File
specifies the number of frequencies exported in each file. A value should be chosen based on the **Number of Modes** field of the **Compute FFT Fields** tab, in order to avoid creating either extremely large output files or a large number of very small files.

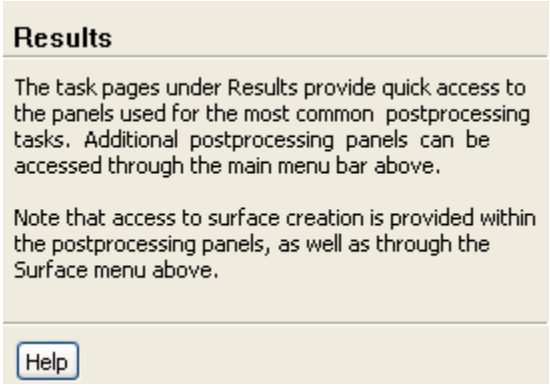
Fourier Transform File Name Root
specifies the root of the names of the output files.

Write
writes CGNS files of the spectrum data.

37.18. Results Task Page

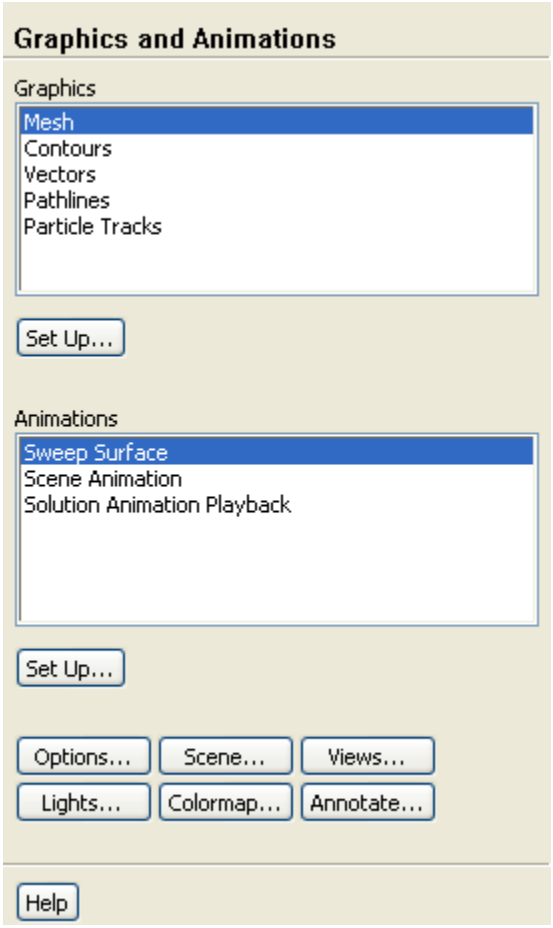
The **Results** task page introduces you to the main tasks involved in setting up and displaying the results of your CFD simulation using ANSYS Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



37.19. Graphics and Animations Task Page

The **Graphics and Animation** task page allows you to visualize the results of your CFD simulation by allowing you to set up plots of contours, vectors, pathlines, particle tracks, scene descriptions and animations. See Displaying Graphics (p. 1747) for more information.



Controls

Graphics

displays a list of the available graphics objects.

You can double-click an item in the **Graphics** list to open the corresponding dialog box, or you can select the item in the list and click the **Set Up...** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mesh
- selecting this item and clicking the **Set Up...** button opens the Mesh Display Dialog Box (p. 2163).

Contours
- selecting this item and clicking the **Set Up...** button opens the Contours Dialog Box (p. 2676).

Vectors
- selecting this item and clicking the **Set Up...** button opens the Vectors Dialog Box (p. 2831).

Pathlines
- selecting this item and clicking the **Set Up...** button opens the Pathlines Dialog Box (p. 2771).

Particle Tracks
- selecting this item and clicking the **Set Up...** button opens the Particle Tracks Dialog Box (p. 2761).

Set Up...
opens the dialog box corresponding to the selected object in the **Graphics** list.

Animations
displays a list of the available animation objects.

You can double-click an item in the **Animations** list to open the corresponding dialog box, or you can select the item in the list and click the **Set Up...** button.

Sweep Surface
- selecting this item and clicking the **Set Up...** button opens the Sweep Surface Dialog Box (p. 2565).

Scene Animation
- selecting this item and clicking the **Set Up...** button opens the Animate Dialog Box (p. 2567).

Solution Animation
- selecting this item and clicking the **Set Up...** button opens the Playback Dialog Box (p. 2571).

Set Up...
opens the dialog box corresponding to the selected object in the **Animations** list.

Options...
opens the Display Options Dialog Box (p. 2573).

Scene...
opens the Scene Description Dialog Box (p. 2577).

Views...
opens the Views Dialog Box (p. 2583).

Lights...
opens the Lights Dialog Box (p. 2588).

Colormap...
opens the Colormap Dialog Box (p. 2589).

Annotate...
opens the Annotate Dialog Box (p. 2592).

For additional information, see the following sections:

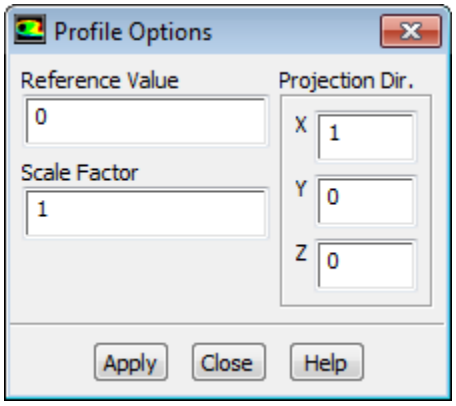
37.19.31. Colormap Editor Dialog Box
37.19.32. Annotate Dialog Box

37.19.1. Profile Options Dialog Box

The **Profile Options** dialog box controls the scaling and projection direction of profiles. It is opened from the Contours Dialog Box (p. 2676), and you will display the profiles using the **Display** button in that dialog box. See Displaying Contours and Profiles (p. 1756) for details about the items below.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

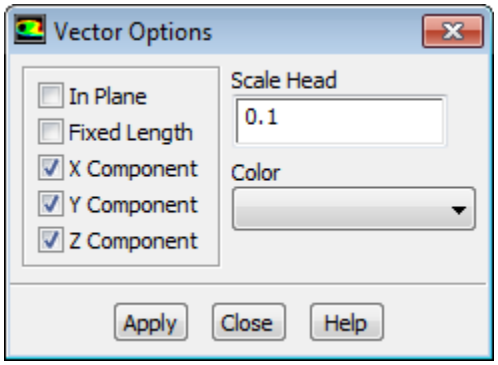
Reference Value
sets the "zero height" reference value for the profile. Any point on the profile with a value equal to the **Reference Value** will be plotted exactly on the defining surface. Values greater than the **Reference Value** will be projected ahead of the surface (in the direction of **Projection Dir.** and scaled by **Scale Factor**), and values less than the **Reference Value** will be projected behind the surface.

Scale Factor
sets the length scale factor for projection. After subtracting off the **Reference Value**, ANSYS Fluent multiplies the resulting solution value by the **Scale Factor** to form a length.

Projection Dir.
sets the direction in which profiles are projected. In 2D, for example, a contour plot of pressure on the entire domain can be projected in the z direction to form a carpet plot, or a contour plot of x velocity on a sequence of x-coordinate slice lines can be projected in the x direction to form a series of velocity profiles.

37.19.2. Vector Options Dialog Box

The **Vector Options** dialog box allows you to set additional parameters for vector displays. It is opened from the Vectors Dialog Box (p. 2831). See Vector Plot Options (p. 1766) for details about the items below.



Controls

In Plane
toggles the display of vector components in the plane of the surface selected for display. This feature is useful for visualizing components that are normal to the flow. See Drawing Vectors in the Plane of the Surface (p. 1767) for details.

Fixed Length
enables the display of vectors that are all the same length. See Displaying Fixed-Length Vectors (p. 1768) for details.

X, Y, Z Component
toggle the display of the Cartesian components of the vectors. See Displaying Vector Components (p. 1768) for details.

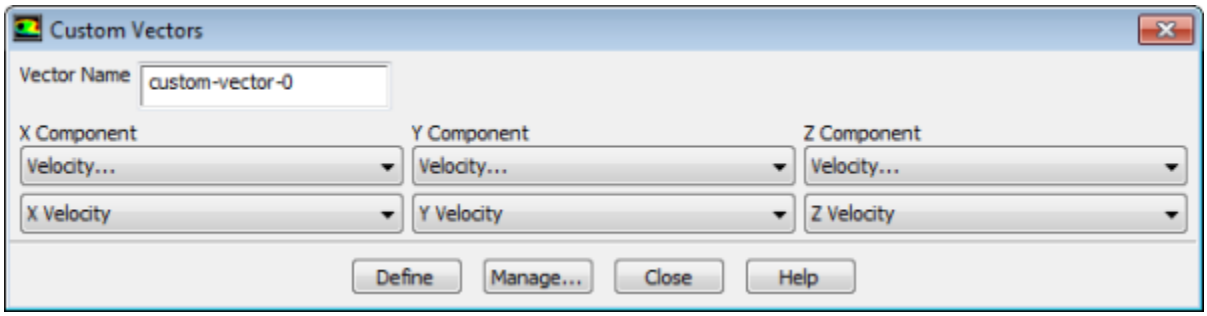
Scale Head
controls the size of the arrowhead on vector styles that include heads.

Color
specifies a single color for the display of all vectors. See Displaying Vectors Using a Single Color (p. 1769) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.19.3. Custom Vectors Dialog Box

The **Custom Vectors** dialog box allows you to define custom vectors based on existing quantities. Any vectors that you define will be added to the **Vectors of** list in the Vectors Dialog Box (p. 2831). To open the **Custom Vectors** dialog box, click **Custom Vectors...** in the **Vectors** dialog box. See Creating and Managing Custom Vectors (p. 1769) for details about custom vectors.



Controls

Vector Name
specifies the name of the vector you are defining. Should you decide to change the name after you have defined the vector, you can do so in the Vector Definitions Dialog Box (p. 2558), which you can open by clicking on the **Manage...** button.

X, Y, Z Component
specify the x, y, and z components of the vector. Each drop-down list contains the available field functions.

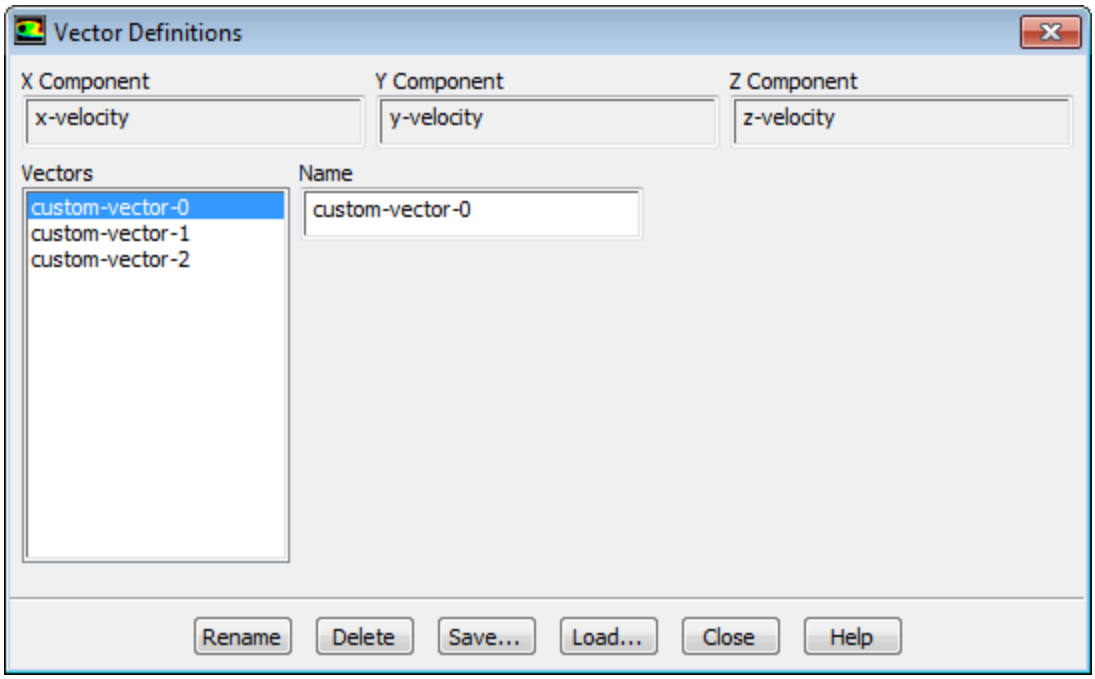
Define
creates the vector and adds it to the **Vectors of** list in the Vectors Dialog Box (p. 2831).

Manage...
opens the Vector Definitions Dialog Box (p. 2558), which enables you to check, rename, save, load, and delete custom vectors.

37.19.4. Vector Definitions Dialog Box

The **Vector Definitions** dialog box allows you to check, rename, save, load, and delete custom vectors that you defined in the Custom Vectors Dialog Box (p. 2558). See Creating and Managing Custom Vectors (p. 1769) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

X, Y, Z Component
display the x, y, and z components of the vector.

Vectors
contains a selectable list of custom vectors. When you select a vector, its components will appear in the **X**, **Y**, and **Z Component** fields, and its name will appear in the **Name** field.

Name
displays the name of the currently selected vector. You can enter a new name in this box if you want to rename the vector.

Rename
changes the name of the selected function to the name specified in the **Name** field.

Delete
deletes the selected vector.

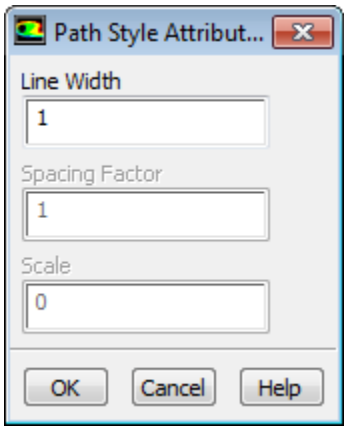
Save...
opens The Select File Dialog Box (p. 19), in which you can specify a file in which to save all of the custom vectors in the **Vectors** list.

Load...
opens the **Select File** dialog box, in which you can specify a file from which to read custom vectors (a file that you saved using the **Save...** button above).

37.19.5. Path Style Attributes Dialog Box

To modify the line width, cylinder radius or marker size, use the **Path Style Attributes** dialog box. You can open this dialog box by clicking the **Attributes...** button in the Pathlines Dialog Box (p. 2771). See Controlling the Pathline Style (p. 1774) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Line Width/Marker Size/Width/
determines the thickness of the pathlines.

Diameter
specifies the diameter of the sphere. This parameter appears only when **sphere** is selected under **Style** in the **Pathlines** dialog box.

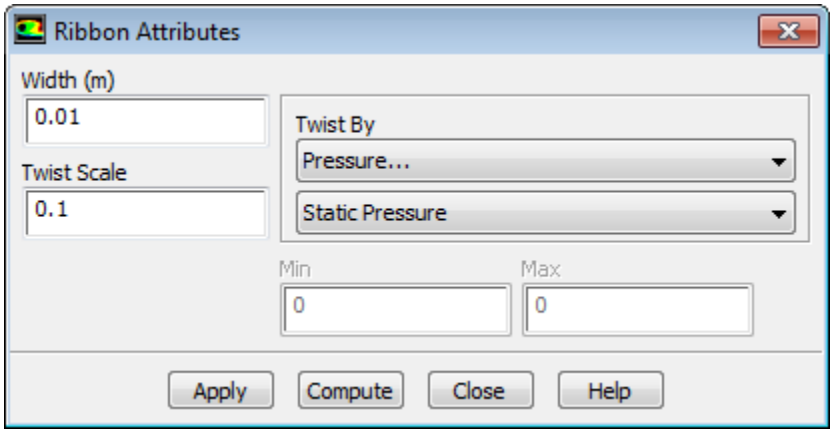
Spacing Factor
controls the spacing of arrows when you use the **line-arrows** style.

Scale
controls the size of the arrow heads when you use the **line-arrows** style.

Detail
specifies the detail applied to the graphical rendering of the spheres. This parameter appears only when **sphere** is selected under **Style** in the **Pathlines** dialog box.

37.19.6. Ribbon Attributes Dialog Box

To modify the ribbon width and set the scalar field by which to twist the ribbon, use the **Ribbon Attributes** dialog box. You can open this dialog box by clicking the **Attributes...** button in the Pathlines Dialog Box (p. 2771) when the selected **Style** is ribbon. See Controlling the Pathline Style (p. 1774) for details about the items below.



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Width
determines the thickness of the ribbon.

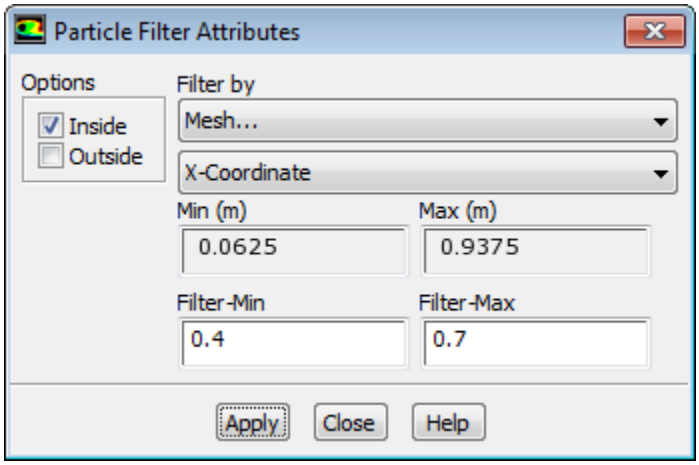
Twist Scale
sets the amount of twist for a given field. To magnify the twist for a field with very little change, increase this factor; to display less twist for a field with dramatic changes, decrease this factor.

Twist By
contains a drop-down list from which you can select a scalar field on which pathline twisting is based.

Min/Max
displays the minimum/maximum value of the scalar field selected in **Twist By**.

37.19.7. Particle Filter Attributes

The **Particle Filter Attributes** dialog box allows you to specify how you would like to filter the particles being displayed. See Particle Filtering (p. 1340) for details about the items below.



Controls

Options
contains the filtering options.

Inside
enables the filtering of particles with values between **Filter-Min** and **Filter-Max**.

Outside
enables the filtering of particles with values less than **Filter-Min** or greater than **Filter-Max**.

Filter by
contains a list from which you can select any field variable, except for **Custom Field Functions...**, to be used as a filter variable.

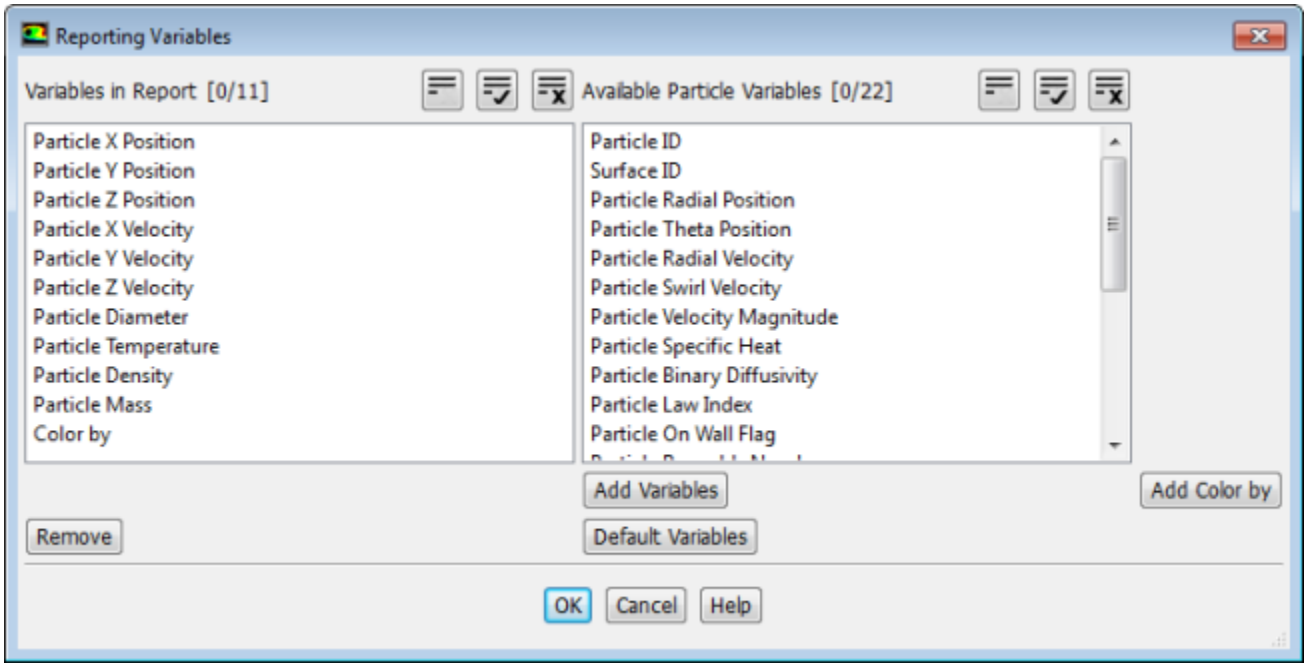
Min/Max
displays the minimum and maximum values of the selected field variable. The real number field values are not editable; they are purely informational.

Filter-Min/Filter-Max
defines the minimum/maximum filter threshold.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.19.8. Reporting Variables Dialog Box

The **Reporting Variables** dialog box allows you to control the particle variables that you include in your reporting. See Step-by-Step Reporting of Trajectories (p. 1347) for details about the items below.



Controls

Variables in Report
contains all variables currently in the report.

Remove
removes the selected variable from the report.

Default Variables
restores the default list.

Available Particle Variables
contains the particle variables that are available for you to select.

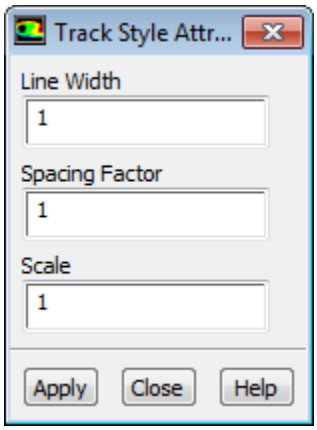
Add Variables
takes the selected variable from the **Available Particle Variables** list and adds it to the **Variables in Report** list.

Add Color By
adds the **Color by** variable to the **Variables in Report** list.

37.19.9. Track Style Attributes Dialog Box

To modify the line width, cylinder radius or marker size, use the **Track Style Attributes** dialog box. You can open this dialog box by clicking the **Attributes...** button in the Particle Tracks Dialog Box (p. 2761). See Controlling the Particle Tracking Style (p. 1332) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

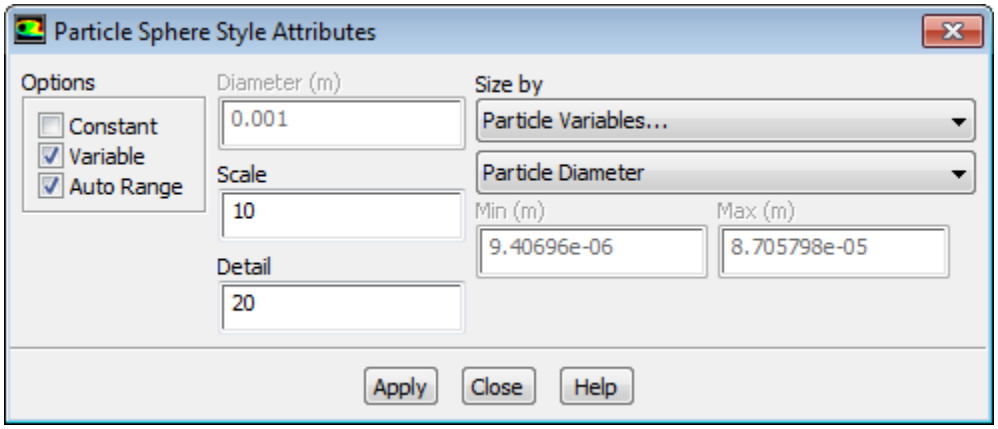
Line Width/Marker Size/Width
determines the thickness of the particle tracks.

Spacing Factor
controls the spacing of arrows when you use the **line-arrows** style.

Scale
controls the size of the arrow heads when you use the **line-arrows** style.

37.19.10. Particle Sphere Style Attributes Dialog Box

To modify the attributes of the particle sphere, use the **Particle Sphere Style Attributes** dialog box. Select **sphere** from the **Track Style** drop-down list and click the **Attributes...** button in the Particle Tracks Dialog Box (p. 2761) to open the **Particle Sphere Style Attributes** dialog box. See Controlling the Particle Tracking Style (p. 1332) for details about the items below.



Controls

Options
allows you to choose how you would like to specify the particle diameter.

Constant
allows you to specify the diameter as a constant value.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Variable
allows you to select a particle variable to estimate the size of the spheres.

Auto Range
when disabled clips the displayed particles to the values given in **Min** and **Max**.

Diameter
specifies the diameter of the sphere.

Scale
allows you to scale the spheres by the factor entered in this field.

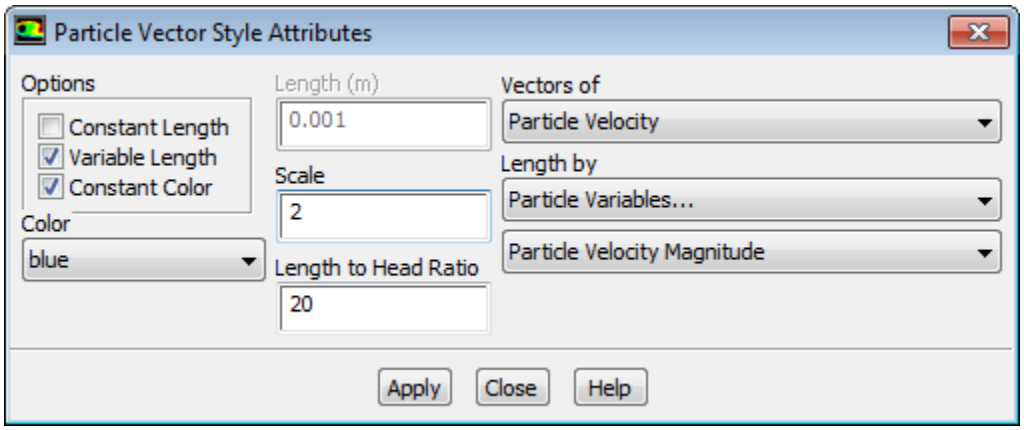
Detail
specifies the detail applied to the graphical rendering of the spheres.

Size by
contains a list of variables by which you can estimate the size of your particle. This list is selectable only when you are using the **Variable** option.

Min/Max
defines the minimum and maximum values of the selected field variable to display.

37.19.11. Particle Vector Style Attributes Dialog Box

To modify the attributes of the vector styles, use the **Particle Vector Style Attributes** dialog box. See Controlling the Vector Style of Particle Tracks (p. 1334) for details about the items below.



Controls

Options
allows you to choose how you would like to specify the particle diameter.

Constant Length
allows you to specify the vector length as a constant value.

Variable Length
results in a vector length that is based on the variable selected under **Length by**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Constant Color
when enabled allows you to select a vector color from the **Color** drop-down list. Otherwise, the vector is colored based on the variable selected in the **Particle Tracks** dialog box (seen in the **Mesh Colors** dialog box when **Draw Mesh** is enabled).

Length
specifies the length of the vector.

Scale
allows you to scale the vectors by the factor entered in this field.

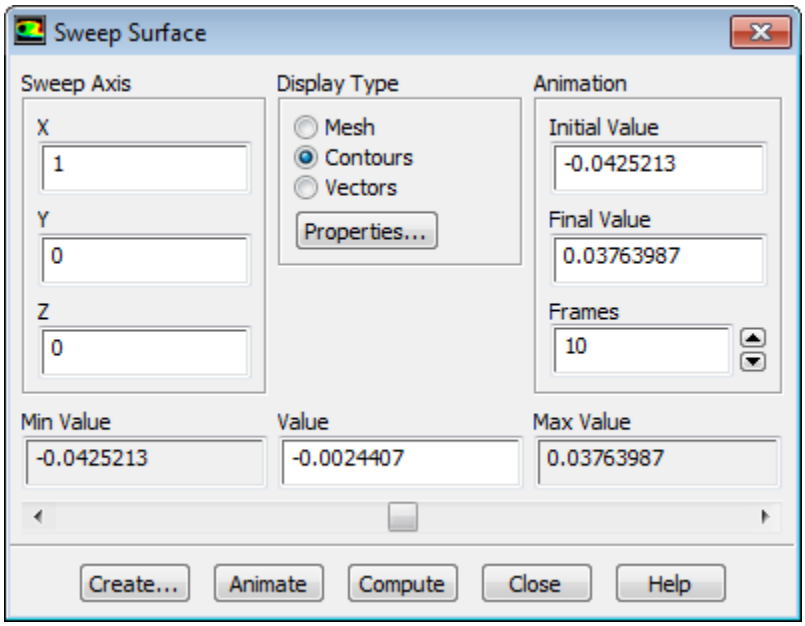
Length to Head Ratio
is the ratio of vector length to vector head size.

Vectors of
contains the particle vector variable to display.

Length by
is used to estimate the length of the vector when the **Variable Length** option is enabled.

37.19.12. Sweep Surface Dialog Box

The **Sweep Surface** dialog box controls the display and animation of mesh, contour, and vector plots generated on a sweep surface. See Displaying Results on a Sweep Surface (p. 1782) for details about the items below.



Controls

Sweep Axis
specifies the (**X**, **Y**, **Z**) vector representing the axis along which the surface should be swept.

Display Type
specifies the type of display to be swept through the domain (**Mesh**, **Contours**, or **Vectors**).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Properties...
opens the Contours Dialog Box (p. 2676) if **Contours** is the selected **Display Type**, or the Vectors Dialog Box (p. 2831) if **Vectors** is the selected **Display Type**. (This button is not available if **Mesh** is the selected **Display Type**.)

Animation
contains controls for animating the sweep-surface display.

Initial Value, Final Value
specify the initial and final positions for the animation.

Frames
specifies the number of frames in the animation.

Min Value, Max Value
show the minimum and maximum extents of the domain along the specified **Sweep Axis**. These values are updated when you click **Compute**.

Value
shows the current position at which the requested display is plotted. You can change the value by moving the slide bar below it, or by entering a new value and pressing the <RETURN> key.

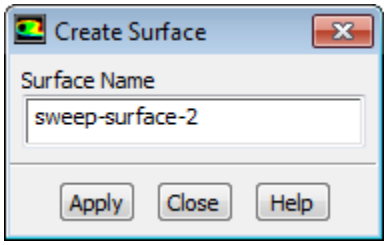
Create...
opens the Create Surface Dialog Box (p. 2566), where you can create a surface from the currently-displayed sweep surface.

Animate
animates the display, sweeping the requested display through the domain along the specified axis.

Compute
updates the **Min Value** and **Max Value** to reflect the minimum and maximum extents of the domain along the specified **Sweep Axis**.

37.19.13. Create Surface Dialog Box

The **Create Surface** dialog box allows you to save a sweep surface for later use. You can open it by clicking **Create...** in the Sweep Surface Dialog Box (p. 2565). See Displaying Results on a Sweep Surface (p. 1782) for details about the items below.



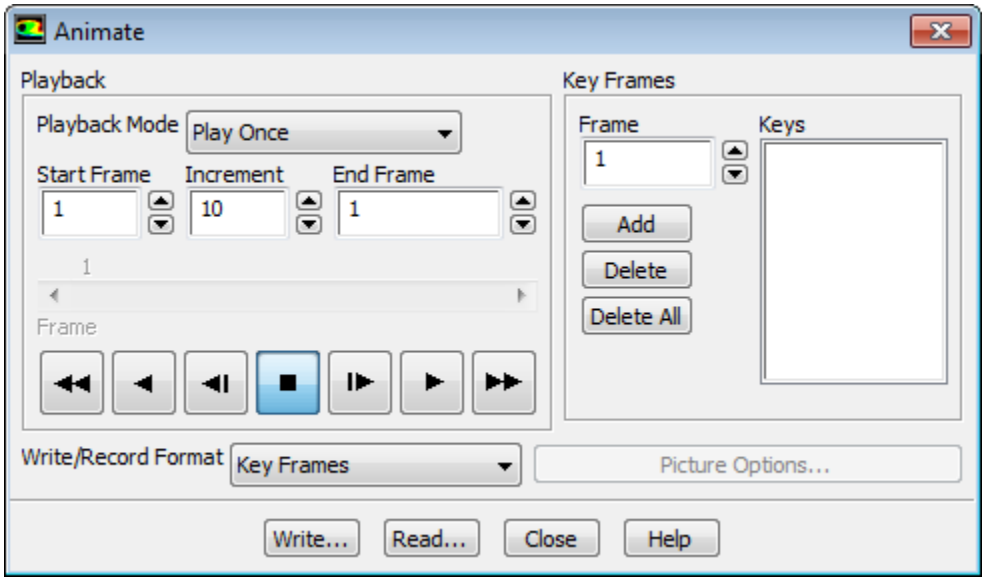
Controls

Surface Name
specifies a name for the surface to be created.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.19.14. Animate Dialog Box

The **Animate** dialog box allows you to specify key frames that define the basic movement of an animated sequence, and then play back the animation. ANSYS Fluent interpolates between your specified key frames. See Animating Graphics (p. 1825) for details about the items below.



Controls

Playback
contains the controls that you use to play back the animation. See Playing an Animation (p. 1826) for details.

Playback Mode
contains a drop-down list of playback options.

Play Once
sets the option to play back frames from **Start Frame** to **End Frame** once.

Auto Repeat
sets the option to continually play back frames from **Start Frame** to **End Frame**.

Auto Reverse
sets the option to continually play back the images while reversing playback direction after each set.

Start Frame, End Frame
set the frames at which the animation should begin and end. By changing these numbers you can view a subset of the frames.

Increment
sets the number of frames to increment the frame-counter by when you use the fast-forward or fast-reverse buttons.

Frame
shows the number of the frame that is currently displayed, as well as its relative position in the entire animation. If you slide the bar to a different location, the frame corresponding to the new frame number will be displayed in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Tape Player Buttons)
allow you to play the animation forward and backward, fast-reverse and fast-forward the animation, and stop it. The buttons function in a way similar to those on a standard video cassette player.

Key Frames
contains the controls that you use to define the key frames for the animation. See Creating an Animation (p. 1826) for details.

Frame
sets the number to be assigned to the next key frame added to the list of **Keys**.

Keys
contains a list of the key frames that have been defined. If you select a key frame in this list, the associated scene will be displayed in the graphics window.

Add
creates a key frame with the number shown in **Frame** for the scene currently displayed in the graphics window.

Important

Be sure to change the frame number before you add the new key frame so that you will not overwrite the last key frame that you created.

Delete
deletes the key frame that is selected in the **Keys** list.

Delete All
deletes all key frames in the **Keys** list.

Write/Record Format
specifies **Key Frames**, **Picture Files**, **MPEG**, or **Video** (not available on Windows) as the format in which to save the animation. See Saving an Animation (p. 1828) for details about these options.

Picture Options...
opens the Save Picture Dialog Box (p. 2568), in which you can specify parameters for saving the animation to picture files. This button is available only when **Picture Files** is selected as the **Write/Record Format**.

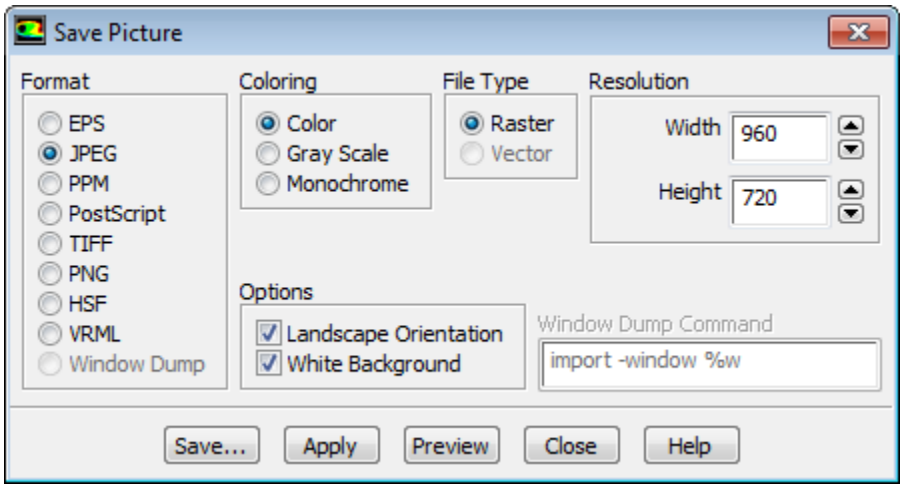
Write...
opens The Select File Dialog Box (p. 19), in which you can specify a name for the animation file and save it.

Read...
opens the **Select File** dialog box, in which you can specify the name of the animation file to be read. Note that the current case and data should contain the surfaces and any other information that the key frame description refers to. See Reading an Animation File (p. 1829).

37.19.15. Save Picture Dialog Box

The **Save Picture** dialog box allows you to set save picture parameters and save picture files of graphics windows. See Saving Picture Files (p. 102) for details on the use of this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Format

allows you to select the format of picture files.

EPS

(Encapsulated PostScript) output is the same as PostScript output, with the addition of Adobe Document Structuring Conventions (v2) statements. Currently, no preview bitmap is included in EPS output. Often, programs that import EPS files use the preview bitmap to display on-screen, although the actual vector PostScript information is used for printing (on a PostScript device). You can save EPS files in raster or vector format.

JPEG

is a common raster file format.

PPM

output is a common raster file format.

PostScript

is a common vector file format. You can also choose to save a PostScript file in raster format.

TIFF

is a common raster file format.

PNG

is a common raster file format.

HSF

is HOOPS Visualize Stream Format, a highly-compressible and streamable 2D/3D file format.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

VRML
is a graphics interchange format that allows export of 3D geometrical entities that you can display in the ANSYS Fluent graphics window. This format can commonly be used by VR systems and in particular the 3D geometry can be viewed and manipulated in a web-browser graphics window.

Important

Non-geometric entities such as text, titles, color bars, and orientation axis are not exported. In addition, most display or visibility characteristics set in ANSYS Fluent, such as lighting, shading method, transparency, face and edge visibility, outer face culling, and hidden line removal, are not explicitly exported but are controlled by the software used to view the VRML file.

Window Dump
(Linux systems only) selects a window dump operation for generating the picture. With this format, you will need to specify the appropriate **Window Dump Command**.

Coloring
(all formats except **Window Dump**) specifies the color mode for the picture file.

Color
specifies a color-scale copy.

Gray Scale
specifies a gray-scale copy.

Monochrome
specifies a black-and-white copy.

Important

Most monochrome PostScript devices will render **Color** images in shades of gray, but to ensure that the color ramp is rendered as a linearly-increasing gray ramp, you should select **Gray Scale**.

File Type
specifies the type of picture file to be saved. See Choosing the File Type (p. 105) for details.

Raster
specifies a raster type picture. The supported raster formats are **EPS**, **JPEG**, **PPM**, **PostScript**, **TIFF**, and **PNG**.

Vector
specifies a vector type picture. The supported vector formats are **EPS**, **PostScript**, and **VRML**.

Resolution
specifies the resolution or the size (in pixels) of the picture.

DPI
specifies the resolution of **EPS** and **PostScript** files in dots per inch (DPI). The default value for **DPI** is set to 75.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Width
specifies the width of the raster picture image.

Height
specifies the height of the raster picture image.

*The default value for **Width** and **Height** is set to zero, so that the default picture is generated at the same resolution as the active graphics window.*

Options
contains additional options for all picture formats except **Window Dump**.

Landscape Orientation
specifies the orientation of the picture. If this option is enabled, the picture is made in landscape mode; otherwise, it is made in portrait mode.

White Background
controls the foreground/background color. If this option is enabled, the foreground and background colors of graphics windows being saved as pictures will be swapped. Hence, it allows you to save pictures with a white background and a black foreground, while the graphics windows are displayed with a black background and white foreground.

Window Dump Command
(Linux systems only) specifies the command to be used to save the picture file, when you select the **Window Dump** format. See Window Dumps (Linux Systems Only) (p. 106) for details.

Save...
opens The Select File Dialog Box (p. 19), in which you can specify a name for the picture file to be saved and then save the file. The resulting file will contain a picture of the active graphics window.

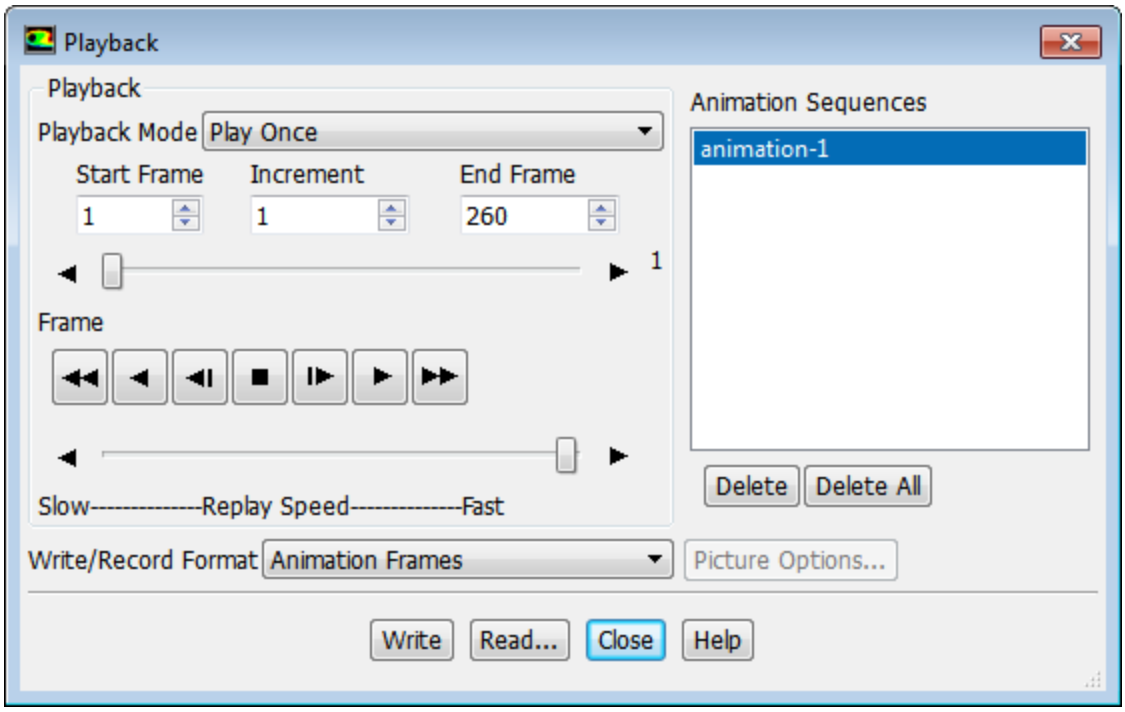
Apply
saves the current settings. ANSYS Fluent will use these settings when making subsequent pictures.

Preview
applies the current settings to the active graphics window so that you can investigate the effects of different options interactively before saving the final picture.

37.19.16. Playback Dialog Box

The **Playback** dialog box allows you to play back an animation sequence. See Playing an Animation Sequence (p. 1650) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Playback
contains the controls that you use to play back the selected animation sequence.

Playback Mode
contains a drop-down list of playback options.

Play Once
sets the option to play back frames from **Start Frame** to **End Frame** once.

Auto Repeat
sets the option to continually play back frames from **Start Frame** to **End Frame**.

Auto Reverse
sets the option to continually play back the images while reversing playback direction after each set.

Start Frame, End Frame
set the frames at which the animation should begin and end. By changing these numbers you can view a subset of the frames.

Increment
sets the number of frames to increment the frame-counter by when you use the fast-forward or fast-reverse buttons.

Frame
shows the number of the frame that is currently displayed, as well as its relative position in the entire animation. If you slide the bar to a different location, the frame corresponding to the new frame number will be displayed in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Tape Player Buttons)
allow you to play the animation forward and backward, fast-reverse and fast-forward the animation, and stop it. The buttons function in a way similar to those on a standard video cassette player.

Replay Speed
controls the playback speed for the animation. Move the **Replay Speed** slider bar to the left to reduce the playback speed (and to the right to increase it).

Animation Sequences
contains the controls that you use to define the sequence to be played back.

Sequences
contains a list of the animation sequences that have been defined.

Delete
deletes the animation sequence that is selected in the **Sequences** list.

Delete All
deletes all animation sequences in the **Sequences** list.

Write/Record Format
specifies **Animation Frames**, **Picture Files**, or **MPEG** as the format in which to save the animation. See Saving an Animation Sequence (p. 1652) for details about these options.

Picture Options...
opens the Save Picture Dialog Box (p. 2568), in which you can specify parameters for saving the animation to picture files. This button is available only when **Picture Files** is selected as the **Write/Record Format**.

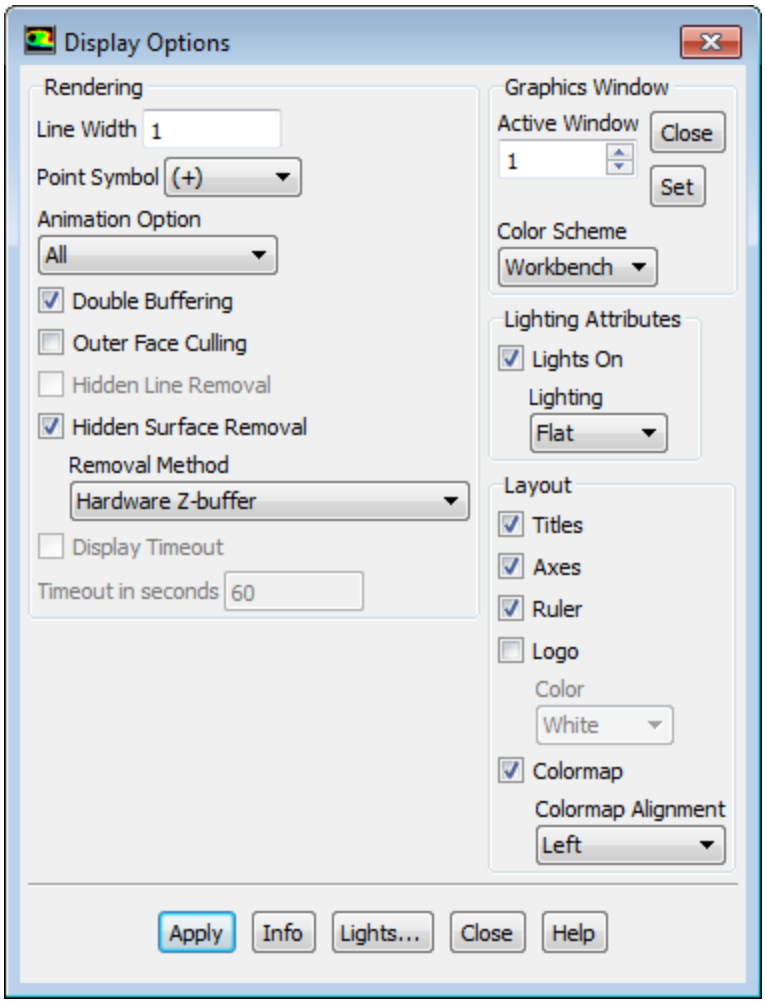
Write
saves the specified file(s) in the current working directory.

Read...
opens The Select File Dialog Box (p. 19), in which you can specify the name of the solution animation file to be read. See Reading an Animation Sequence (p. 1654) for details.

37.19.17. Display Options Dialog Box

The **Display Options** dialog box provides an interactive mechanism for setting attributes or options that control how and where a scene is rendered.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Rendering

allows you to modify characteristics of the display that are related to the way in which scenes are rendered. See Modifying the Rendering Options (p. 1798) for details about these items.

Line Width

controls the thickness of lines. The default is 1.

Point Symbol

sets the symbol used for nodes and data points.

Animation Option

contains a drop-down list of animation options: **All** and **Wireframe**. **Wireframe** uses a wireframe representation of all geometry during mouse manipulation This option is turned on by default. You should turn it off only if your computer has a graphics accelerator; otherwise the mouse manipulation may be very slow.

Double Buffering

turns double buffering on or off, if it is supported by the driver. Double buffering dramatically reduces screen flicker during graphics updates. Note that if your display hardware does not support double buffering and you turn this option on, double buffering will be done in software. Software double buffering uses extra memory.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Outer Face Culling
allows you to turn off the display of outer faces in wall zones. **Outer Face Culling** is useful for displaying both sides of a slit wall. By default, when you display a slit wall, one side will "bleed" through to the other. When you turn on the **Outer Face Culling** option, the display of a slit wall will show each side distinctly as you rotate the display. This option can also be useful for displaying two-sided walls (walls with fluid or solid cells on both sides).

Hidden Line Removal
turns hidden line removal on or off. If you do not use hidden line removal, ANSYS Fluent will not try to determine which lines in the display are behind others; it will display all of them, and a cluttered display will result. You should turn this option off if you are working with a 2D problem or with geometries that do not overlap. Note that this option is not available when using the **Workbench Color Scheme**.

Hidden Surface Removal
turns hidden surface removal on or off. If you do not use hidden surface removal, ANSYS Fluent will not try to determine which surfaces in the display are behind others; it will display all of them, and a cluttered display will result. You should turn this option off if you are working with a 2D problem or with geometries that do not overlap.

Removal Method
chooses the method to be used for hidden surface removal. These options vary in speed and quality, depending on the device you are using. The choices are listed below.

Hardware Z-buffer
is the fastest method if your hardware supports it. The accuracy and speed of this method is hardware dependent.

Painters
will show fewer edge-aliasing effects than hardware-z-buffer. This method is often used instead of software-z-buffer when memory is limited.

Software Z-buffer
is the fastest of the accurate software methods available (especially for complex scenes), but it is memory intensive.

Z-sort only
is a fast software method, but it is not as accurate as software-z-buffer.

Timeout in seconds
specifies the value for the timeout.

Graphics Window
allows you to open and close graphics windows. See Opening Multiple Graphics Windows (p. 1786) for details.

Active Window
indicates the graphics window to be opened, closed, or set active. (A graphics window's ID is displayed in its title.)

Open/Close
opens or closes the window with the ID shown in the **Active Window** box. If the indicated window is open, the **Close** button will appear, and if the indicated window is not open, the **Open** button will appear.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set
sets the window with the ID shown in the **Active Window** box to be the active graphics window. See Setting the Active Window (p. 1787) for details.

Color Scheme
contains a drop-down list of available graphics window color schemes to choose from. Choices are **Workbench** (blue background) and **Classic** (black background).

Lighting Attributes
controls lighting attributes for all lights in the active graphics window. See Adding Lights (p. 1796) for details.

Lights On
turns *all* lights in the active graphics window on or off.

Lighting
specifies the method to be used in lighting interpolation: **Flat**, **Gouraud**, or **Phong**. (**Flat** is the most basic method: there is no interpolation within the individual polygonal facets. **Gouraud** and **Phong** have smoother gradations of color because they interpolate on each facet.)

Layout
controls the display of captions, axes and the colormap in the graphics display window. See Changing the Legend Display (p. 1788) for details.

Titles
enables/disables the display of all captions in the graphics display window.

Axes
enables/disables the display of the axis triad.

Ruler
enables/disables the display of the ruler.

Logo
allows you to hide or display the ANSYS logo.

Color
contains a drop-down list of colors that can be used for the logo. The choices are **White** (default) or **Black**.

Colormap
enables/disables the display of the color scale.

Colormap Alignment
allows you to adjust the alignment of colormap in the graphics display. Select the side (**Top**, **Bottom**, **Left**, and **Right**) from the drop-down list, where you want to align the colormap.

Apply
applies the specified attributes and re-renders the scene in the active graphics window with the new attributes. To see the effect of the new attributes on other graphics windows, you must redisplay them.

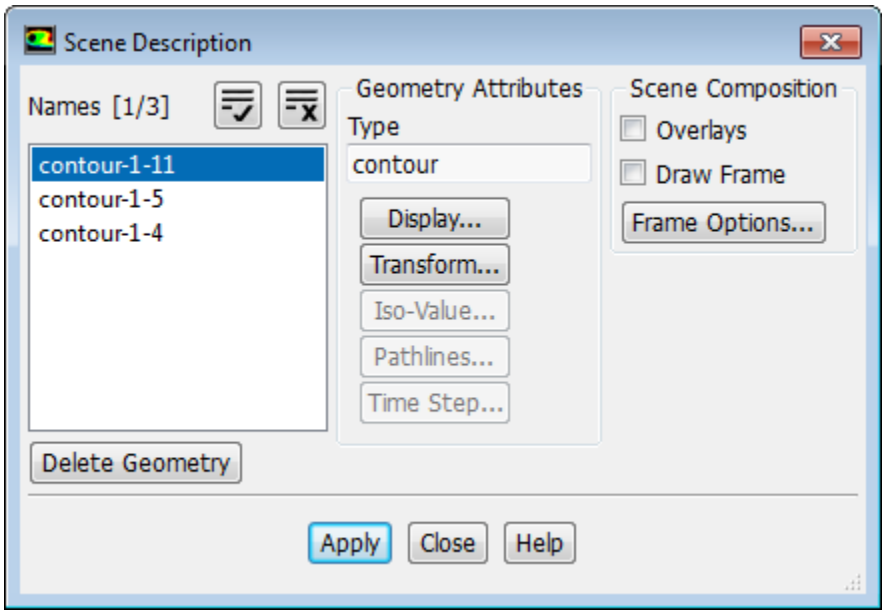
Info
prints out information about your graphics driver in the console.

Lights...
opens the Lights Dialog Box (p. 2588), which allows you to create, delete, and modify directional light sources.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.19.18. Scene Description Dialog Box

The **Scene Description** dialog box allows you to turn overlays on and off, select geometric objects in the display for modification or deletion, and open dialog boxes that control various characteristics of the selected object(s). (Note that you cannot use the **Scene Description** dialog box to control XY plot and histogram displays.) See Advanced Scene Composition (p. 1815) for details about the items below.



Controls

Names

contains a list of the geometric objects that currently exist in the scene (including those that are presently invisible). You can specify the object or objects to be manipulated by selecting names in this list. If you select more than one object at a time, any operation (transformation, color specification, and so on) will apply to all the selected objects. You can also select objects by clicking on them in the graphics display using the mouse probe button, which is, by default, the right mouse button. (See Controlling the Mouse Button Functions (p. 1800) for information about mouse button functions.) To deselect a selected object, simply click its name in the **Names** list. See Selecting the Object(s) to be Manipulated (p. 1817) for details.

Geometry Attributes

contains information about the type of the selected geometric object and push buttons that open dialog boxes for modifying the object.

Type

reports the type of the selected object. Possible types include `mesh`, `surface`, `contour`, `vector`, and `Group`. This information is especially helpful when you need to distinguish two or more objects with the same name. When more than one object is selected, the type displayed is `Group`.

Display...

opens the Display Properties Dialog Box (p. 2578), which allows you to change the color, visibility, and other properties for the selected object.

Transform...

opens the Transformations Dialog Box (p. 2580), which allows you to translate, rotate, and scale the selected object.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Iso-Value...
opens the Iso-Value Dialog Box (p. 2581), which allows you to change the isovalue of an isosurface. This push button is available only if the geometric object selected in the **Names** list is an isosurface or an object on an isosurface (contour on an isosurface, for example); otherwise it is grayed out.

Pathlines...
opens the Pathline Attributes Dialog Box (p. 2582), which allows you to set the maximum number of steps for the selected pathlines. This is most useful in animating the path of a set of particles.

Scene Composition
contains controls for enabling overlays and bounding frames.

Overlays
activates the superimposition of a new geometry onto a currently displayed geometry. See Advanced Graphics Overlays (p. 1785) for details.

Draw Frame
activates the display of a bounding frame in the graphics display. See Adding a Bounding Frame (p. 1823) for details.

Frame Options...
opens the Bounding Frame Dialog Box (p. 2582), in which you can define properties of the bounding frame. See Adding a Bounding Frame (p. 1823) for details.

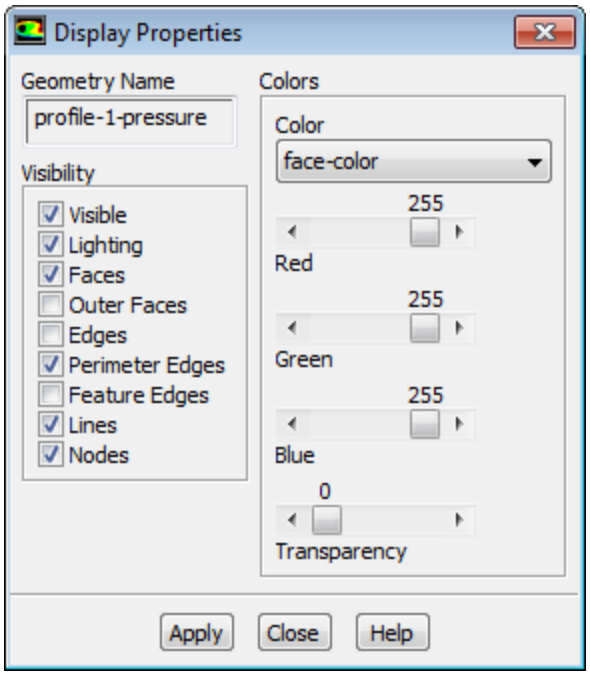
Delete Geometry
deletes the geometric object that is currently selected in the **Names** list. The ability to delete individual objects is especially useful if you have overlays on and you generate an unwanted object (for example, if you generate contours of the wrong variable). You can simply delete the unwanted object and continue your scene composition, instead of starting over from the beginning.

Apply
saves the status of **Overlays** and **Draw Frame**. When you turn **Overlays** or **Draw Frame** on or off, you must click the **Apply** button to see the effect of the change on subsequent display operations.

37.19.19. Display Properties Dialog Box

To modify the color, visibility, and other display properties for individual geometric objects in the graphics display, use the **Display Properties** dialog box. You can open this dialog box by clicking the **Display...** push button in the Scene Description Dialog Box (p. 2577). See Changing an Object's Display Properties (p. 1817) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Geometry Name
displays the name of the object you selected for modification in the Scene Description Dialog Box (p. 2577).

Visibility
contains check buttons that control options related to the visibility of the selected object. See Controlling Visibility (p. 1818) for details.

Visible
toggles the visibility of the selected object. If it is turned on, the object will be visible in the display, and if it is turned off, the object will be invisible.

Lighting
turns the effect of lighting for the selected object on or off. You can choose to have lighting affect only certain objects instead of all of them. Note that if **Lighting** is turned on for an object such as a contour or vector plot, the colors in the plot will not be exactly the same as those in the colormap at the left of the display.

Faces
toggles the filled display of faces for the selected mesh or surface object. Turning **Faces** on has the same effect as turning on the display of faces in the Mesh Display Dialog Box (p. 2163).

Outer Faces
toggles the display of outer faces.

Edges
toggles the display of interior and exterior edges of the geometric object.

Perimeter Edges
toggles the display of the outline of the geometric object. (This option has no effect on the display of meshes.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Feature Edges
toggles the display of feature lines (if any) of the geometric object.

Lines
toggles the display of the lines (if any) in the geometric object.

Nodes
toggles the display of the nodes (if any) in the geometric object.

Colors
contains controls for setting face, edge, line, and node colors, and transparency for faces. See Controlling Object Color and Transparency (p. 1818) for details.

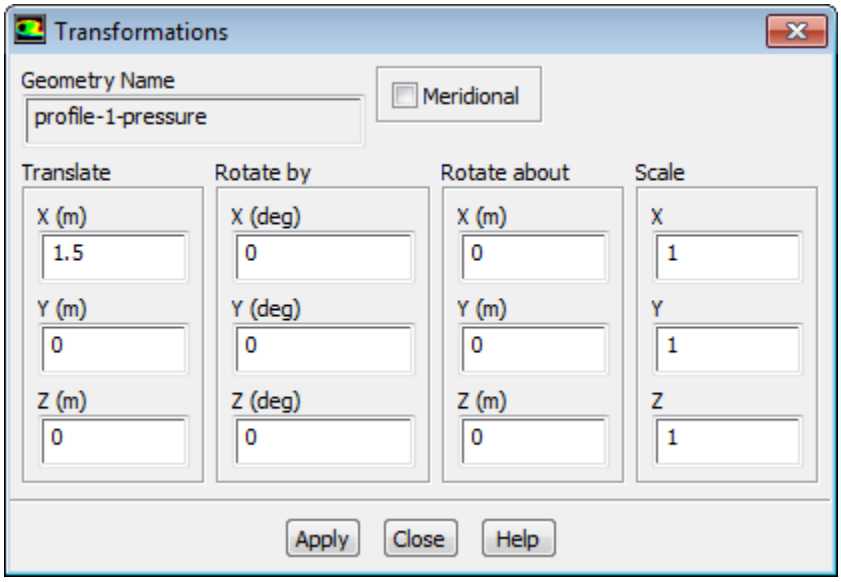
Color
specifies the face, edge, line, or node color for modification. When you turn on this button, the color scales below will show the current color specification, which you can modify by moving the sliders on the color scales.

Red, Green, Blue
are color scales with which you can specify the RGB components of the face, edge or line color.

Transparency
sets the relative transparency of the selected object. An object with a transparency of 0 is opaque, and an object with a transparency of 100 is transparent.

37.19.20. Transformations Dialog Box

You can use the **Transformations** dialog box to translate, rotate, or scale individual objects in the graphics display. To open this dialog box, click the **Transform...** push button in the Scene Description Dialog Box (p. 2577). See Transforming Geometric Objects in a Scene (p. 1819) for details about the items below.



Controls

Geometry Name
displays the name of the object you selected for modification in the Scene Description Dialog Box (p. 2577).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Meridional
(3D only) enables the display of the meridional view. This option is especially useful in turbomachinery applications.

Translate
contains **X**, **Y**, and **Z** real number fields in which you can enter the distance by which to translate the selected object in each direction.

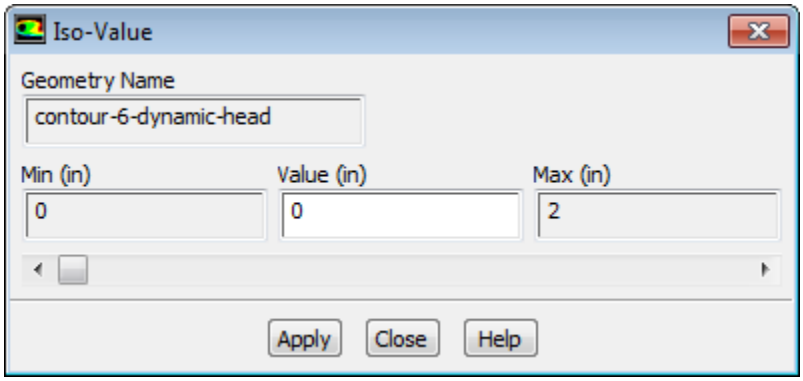
Rotate by
contains **X**, **Y**,and **Z** integer number fields in which you can enter the number of degrees by which to rotate the selected object about each axis.

Rotate about
specifies the point about which to rotate the object.

Scale
contains **X**, **Y**, and **Z** real number fields in which you can enter the amount by which to scale the selected object in each direction. To avoid distortion of the object's shape, be sure to specify the same value for all three entries.

37.19.21. Iso-Value Dialog Box

The **Iso-Value** dialog box allows you to change the isovalue of an isosurface. The isosurface can be selected directly in the **Names** list or indirectly by selecting an object displayed on the isosurface. When you change the isovalue, any contours, vectors, and so on that were displayed on the original isosurface will be displayed on the isosurface with the new isovalue. To open this dialog box, click the **Iso-Value...** push button in the Scene Description Dialog Box (p. 2577). See Modifying Iso-Values (p. 1821) for details about using this dialog box.



Controls

Geometry Name
displays the name of the geometric object (isosurface) you selected for modification in the Scene Description Dialog Box (p. 2577).

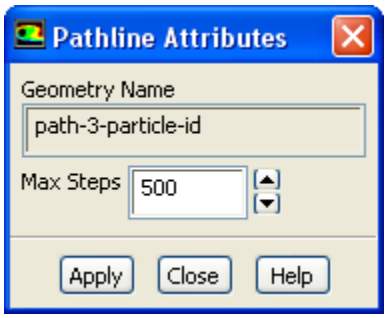
Min, Max
show the minimum and maximum values of the isosurface variable.

Value
sets the new isovalue for isosurfaces. After you change the value and click **Apply**, contours, vectors, or pathlines that were displayed on the original isosurface will be displayed for the new isovalue. You can also use the slide bar to change the **Value**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.19.22. Pathline Attributes Dialog Box

The **Pathline Attributes** dialog box allows you to change the number of steps used in the computation of pathlines. This is most useful in creating animations of pathlines. To open this dialog box, click the **Pathlines...** button in the Scene Description Dialog Box (p. 2577). See Modifying Pathline Attributes (p. 1822) for details about using this dialog box.



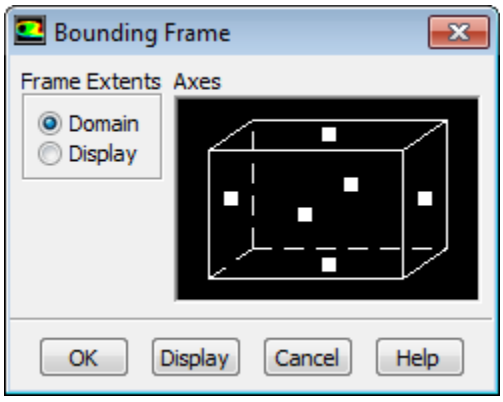
Controls

Geometry Name
displays the name of the geometric object you selected for modification in the Scene Description Dialog Box (p. 2577).

Max Steps
sets the new maximum number of steps for pathline computation. After you change the value and click **Apply**, the selected pathline will be recomputed and redrawn.

37.19.23. Bounding Frame Dialog Box

The **Bounding Frame** dialog box allows you to add a bounding frame with optional measure markings to the display of the domain. See Adding a Bounding Frame (p. 1823) for details about the items in this dialog box.



Controls

Frame Extents
indicates the extents of the bounding frame.

Domain
specifies that the frame should encompass the domain extents.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

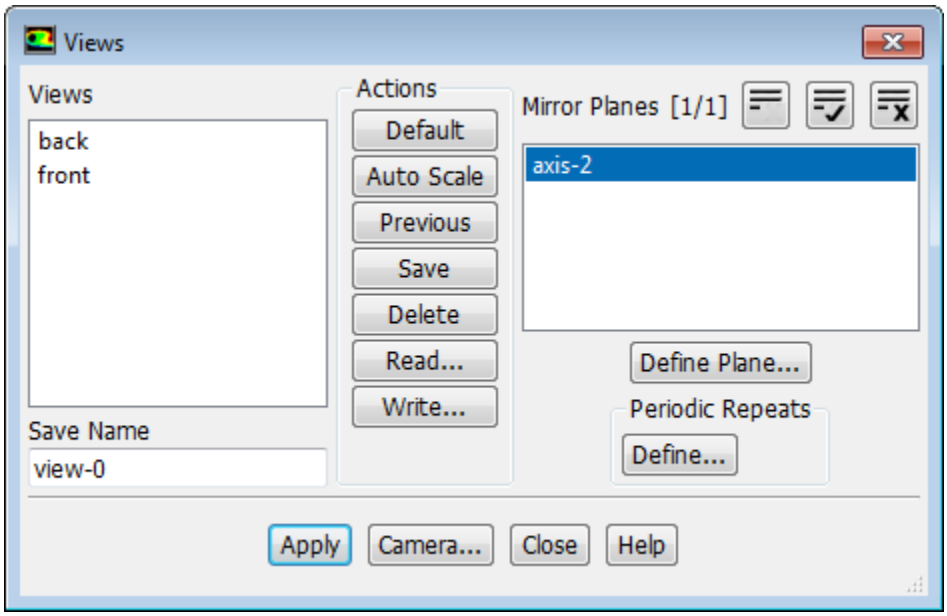
Display
specifies that the frame should encompass the portion of the domain that is shown in the display.

Axes
contains controls for specifying the frame boundaries and measurements. See Adding a Bounding Frame (p. 1823) for instructions on using these items.

Display
updates the active graphics window with the current frame settings.

37.19.24. Views Dialog Box

With the **Views** dialog box, you can make various modifications to the view displayed in the active graphics window. See Modifying the View (p. 1803) for details about the items below.



Controls

Views
lists the currently defined views. Clicking on a view name highlights that name and enters it into the **Name** field. Double-clicking on a view name restores that view in the active graphics window.

Save Name
specifies the name to use when saving a view.

Actions
contains buttons for performing various actions related to the **Views** list and the **Save Name**.

Default
restores the "front" view in the active graphics window.

Auto Scale
modifies the view in the active graphics window by scaling and centering the current scene without changing its orientation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Previous
allows you to return to previous displays.

Save
stores the view in the active graphics window with the name in the **Save Name** box. See Saving Views (p. 1810) for details.

Delete
removes the selected view name from the **Views** list.

Important

Be careful not to delete any of the pre-defined views.

Read...
opens The Select File Dialog Box (p. 19), in which you can specify the name of a view file to be read. See Reading View Files (p. 1810) for details.

Write...
opens the Write Views Dialog Box (p. 2584), in which you can select the views to be saved to a view file. See Saving Views (p. 1810) for details.

Mirror Planes
displays a list of all symmetry planes in the domain. Mirror images are drawn for all selected symmetry planes. See Mirroring and Periodic Repeats (p. 1811) for details.

Define Plane...
opens the Mirror Planes Dialog Box (p. 2585), in which you can define a mirror plane for a non-symmetric domain.

Periodic Repeats
indicates the number of periodic repetitions to be displayed. See Mirroring and Periodic Repeats (p. 1811) for details.

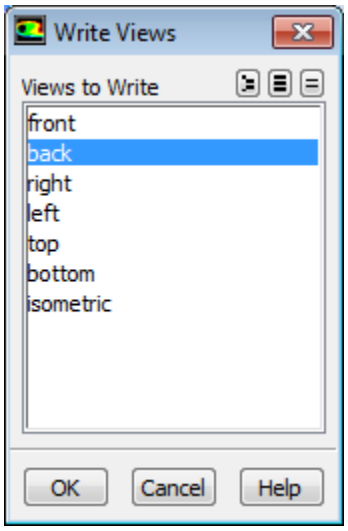
Define...
opens the Graphics Periodicity Dialog Box (p. 2586), in which you can define periodicity for a periodic domain.

Camera...
opens the Camera Parameters Dialog Box (p. 2587).

37.19.25. Write Views Dialog Box

The **Write Views** dialog box allows you to save selected views to a view file. To open it, click **Write...** in the Views Dialog Box (p. 2583). This feature allows you to transfer views between case files. See Saving Views (p. 1810) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

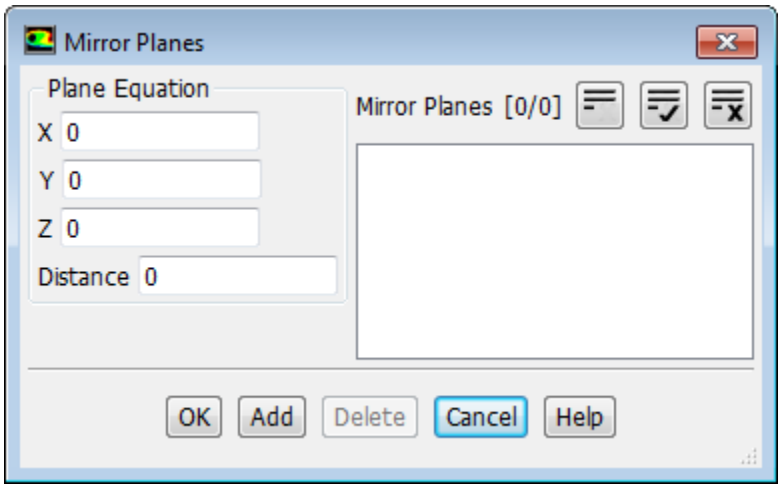


Controls

Views to Write
is a selectable list of the defined views. The selected views will be saved to a view file when you click **OK**.

37.19.26. Mirror Planes Dialog Box

The **Mirror Planes** dialog box allows you to define a symmetry plane for a non-symmetric domain for use with graphics. To open it, click **Define Plane...** in the Views Dialog Box (p. 2583). See Mirroring for Graphics (p. 1815) for details.



Controls

Plane Equation
contains inputs for specifying the equation for the mirror plane: A **X** + B **Y**+ C **Z** = **Distance**.

Mirror Planes
contains a list of all mirror planes you have defined using this dialog box. (Mirror planes that exist in the domain due to symmetry will not appear in this list, since they cannot be modified.)

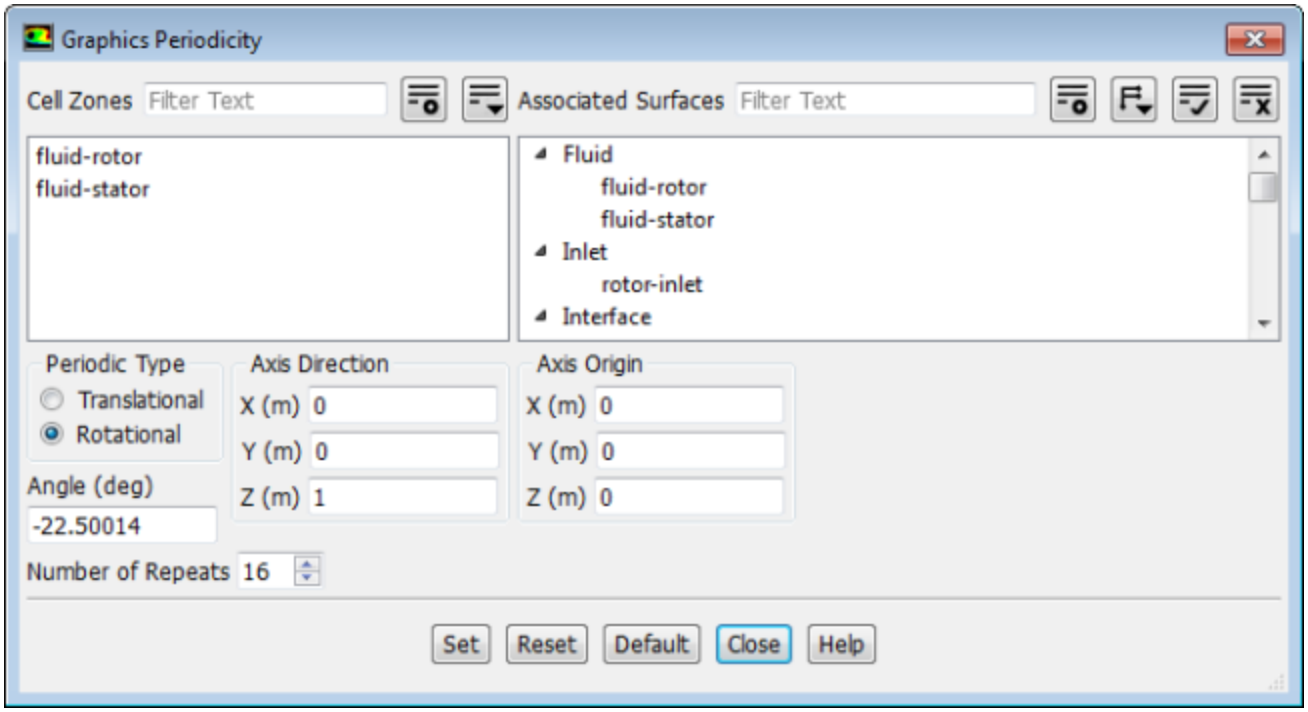
Add
adds the plane defined by the **Plane Equation** to the **Mirror Planes** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Delete
deletes the plane(s) selected in the **Mirror Planes** list.

37.19.27. Graphics Periodicity Dialog Box

The **Graphics Periodicity** dialog box allows you to define a periodic repeats, periodic rotation or translation for a non-periodic domain for use with graphics. To open it, click **Define...** under **Periodic Repeats** in the Views Dialog Box (p. 2583). See Periodic Repeats for Graphics (p. 1813) for details.



Controls

Cell Zones
contains the list of the zones in the mesh. You can select one or more zones in this list and specify different periodicity parameters for each zone separately.

Associated Surfaces
contains the list of the surfaces associated with the selected cell zone.

Periodic Type
specifies **Rotational** or **Translational** periodicity.

Angle
specifies the angle by which the domain is rotated to create the periodic repeat. This item is available when you select **Rotational** as the **Periodic Type**.

Translation
specifies the distance in the **X**, **Y**, and **Z** directions by which the domain is translated to create the periodic repeat. This item will appear when you select **Translational** as the **Periodic Type**.

Axis Direction
specifies the direction vector (**X,Y,Z**) for the axis of rotation. This item is available when you select **Rotational** as the **Periodic Type** and the domain is three-dimensional.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axis Origin
specifies the origin of the axis of rotation. This item is available when you select **Rotational** as the **Periodic Type**.

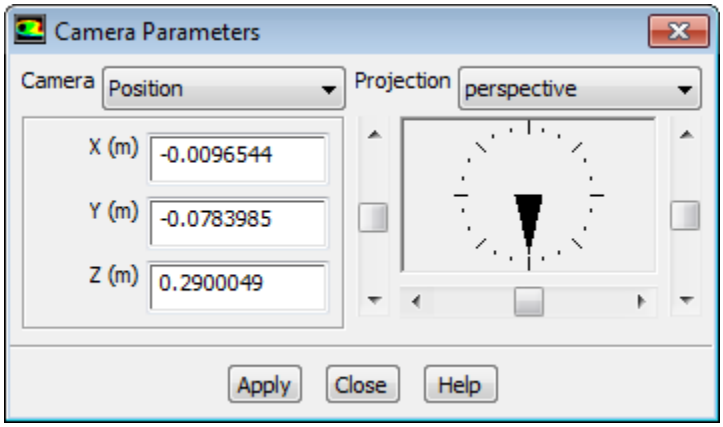
Number of Repeats
specifies the number of times you want to repeat the periodic domain.

Set
applies the periodicity you have defined for the case setup.

Reset
removes any periodicity you have defined, and returns to the default periodicity for the domain (no periodicity for a non-periodic domain).

37.19.28. Camera Parameters Dialog Box

The **Camera Parameters** dialog box allows you to modify the "camera" through which you are viewing the graphics display. See Controlling Perspective and Camera Parameters (p. 1808) for details about the items below.



Controls

Camera
contains a drop-down list of the parameters that define the camera (**Position**, **Target**, **Up Vector**, and **Field**) and **X**, **Y**, and **Z** fields in which you can define the coordinates or field distances for the parameter selected in the drop-down list. Figure 31.43: Camera Definition (p. 1809) illustrates the definition of the camera by these parameters.

Projection
contains a drop-down list that allows you to select a **Perspective** or **Orthographic** view.

(Dial and Sliders)
allow you to rotate and scale the graphics display. The slider on the scale to the left of the dial rotates the display about the horizontal axis at the center of the screen, the slider on the scale below the dial rotates the display about the vertical axis at the center of the screen, and the dial controls rotation about the axis

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

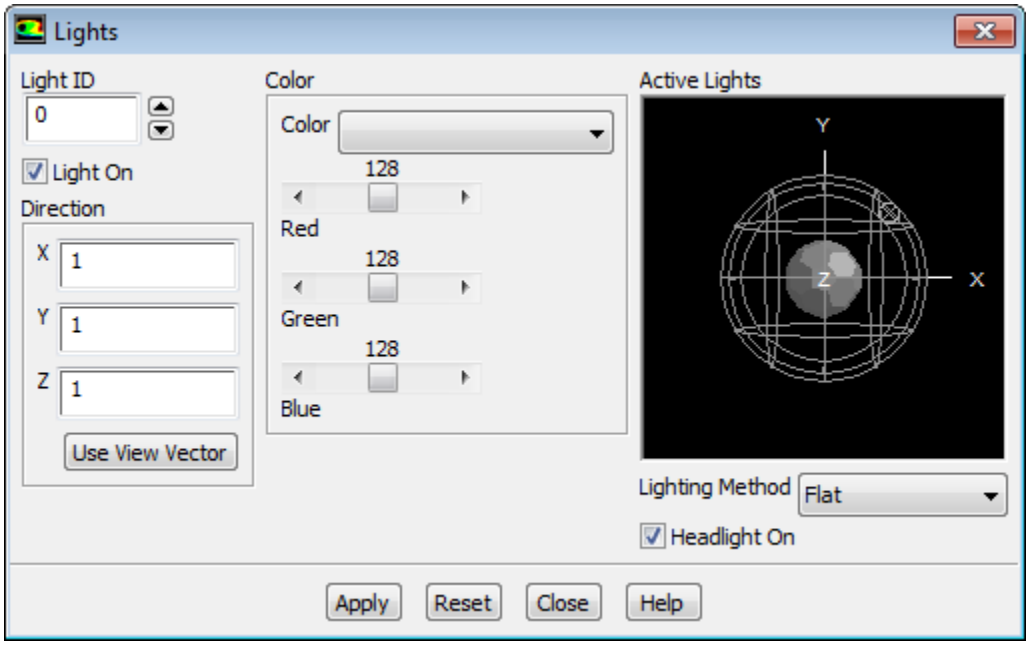
at the center of and perpendicular to the screen. The slider on the scale to the right of the dial zooms in or out in the display. See Rotating the Display (p. 1805) and Zooming the Display (p. 1807) for details.

Important

When you are using the sliders and dial to manipulate the view, you may want to turn off **Wireframe Animation** in the Display Options Dialog Box (p. 2573), so that you can watch the display move interactively while you are moving the slider or the dial indicator.

37.19.29. Lights Dialog Box

The **Lights** dialog box provides an interactive mechanism for placing colored, directional lights in a scene. See Adding Lights (p. 1796) for details about the items below.



Controls

Light ID
indicates the light that is being added, deleted, or modified. By default, light 1 is defined to be dark gray with a direction of (1,1,1).

Light On
indicates whether or not the light specified in **Light ID** is on or off. By turning off the **Light On** option for a particular light, you can remove this light from the display, while still retaining its definition. To add it to the display again, simply turn on the **Light On** button.

Direction
allows you to specify the direction of the light (the position on the unit sphere from which the light emanates) by entering the **X**, **Y**, and **Z** coordinates or by computing the coordinates based on the current view in the graphics window.

X,Y,Z
specify the direction of the light. For example, the direction (1,1,1) means that the rays from the light will be parallel to the vector from (1,1,1) to the origin.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use View Vector

updates the **X,Y,Z** fields with the appropriate values for the current view in the active graphics window, and shines a light in that direction. Instead of entering the **X,Y,Z** values for a light's direction vector, you can use your mouse to change the view in the graphics window so that your position in reference to the geometry is the position from which you would like a light to shine. You can then click the **Use View Vector** button to update the **X,Y,Z** fields with the appropriate values for your current position and update the graphics display with the new light direction. This method is convenient if you know where you want a light to be, but you are not sure of the exact direction vector.

Color

allows you to specify the light color with sliders. You can create your desired color by increasing and decreasing the slider values for the colors **Red**, **Green**, and **Blue**. You can also enter a descriptive string (for example, lavender) in the **Color** field.

Active Lights

shows the position and color of all defined directional lights, and allows you to change the position of a light. All directional lights in ANSYS Fluent are assumed to be at infinity and pass through the unit sphere at the position shown. All light rays arriving at the scene from one light are parallel. The colored markers on the surface of the sphere represent the color and direction of these *distant* lights. These lights point towards the center of the sphere (the origin, which is usually where the geometry is).

Lighting Method

specifies the method to be used in lighting interpolation: **Off**, **Flat**, **Gouraud**, or **Phong**. (**Flat** is the most basic method: there is no interpolation within the individual polygonal facets. **Gouraud** and **Phong** have smoother gradations of color because they interpolate on each facet.) When **Off** is selected, lighting effects are disabled.

Headlight On

enables constant lighting effects in the direction of the view.

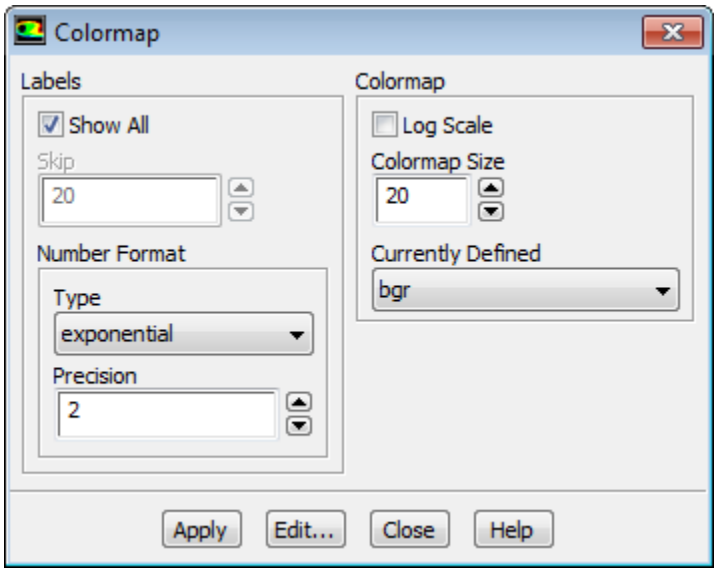
Reset

resets the light definitions to their last saved state (the lighting that was in effect the last time you opened the dialog box or clicked on **Apply**).

37.19.30. Colormap Dialog Box

The **Colormap** dialog box allows you to select and modify existing colormaps. See Selecting a Colormap (p. 1793) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Labels
allows you to customize the display of your colormap labels.

Show All
Enable this option if you want all the labels to show alongside the colormap. Disable if you want to skip some of the label displays.

Skip
sets the number of labels to be skipped.

Number Format
contains controls for changing the format of the labels on the color scale. These labels are the character strings used to define the color divisions at the left of the graphics window.

Type
sets the form of the labels. You may select from a drop-down list of options, including the following:

general
displays the real value with either float or exponential form based on the size of the number and the defined **Precision**.

float
displays the real value with an integral and fractional part (for example, 1.0000), where the number of digits in the fractional part is determined by **Precision**.

exponential
displays the real value with a mantissa and exponent (for example, 1.0e-02), where the number of digits in the fractional part of the mantissa is determined by **Precision**.

Precision
defines the number of fractional digits displayed in the labels.

Colormap
contains controls for the colormap size and scale, and for selection of a defined colormap.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Log Scale
enables the use of a logarithmic scale for the color scale (rather than the default decimal scale). See Specifying the Colormap Size and Scale (p. 1793) for details.

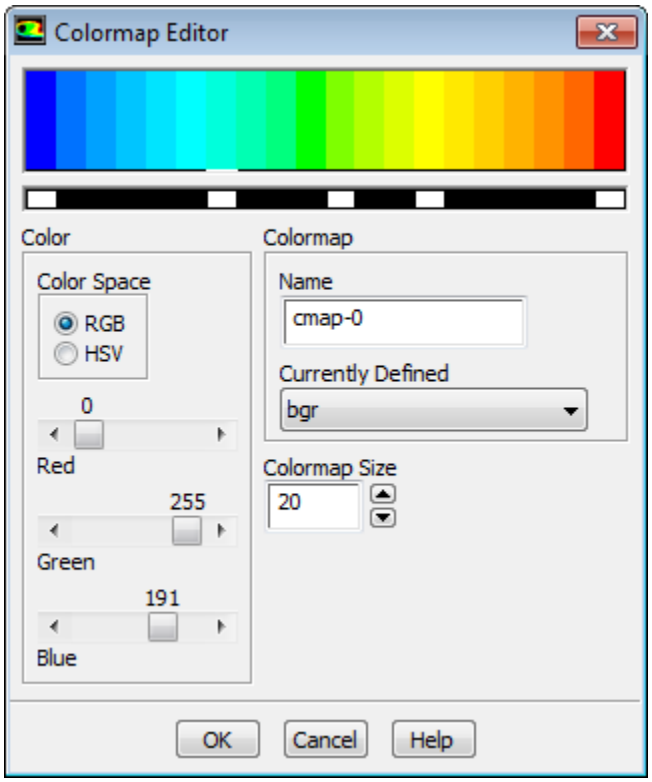
Colormap Size
specifies the number of distinct colors in the colormap. You may specify from 2 to 100 colors.

Currently Defined
contains a drop-down list of all pre-defined colormaps and all custom colormaps defined by you. Select the colormap to be used from this list.

Edit...
opens the Colormap Editor Dialog Box (p. 2591), in which you can create a custom colormap.

37.19.31. Colormap Editor Dialog Box

The **Colormap Editor** dialog box allows you to create custom colormaps. See Creating a Customized Colormap (p. 1795) for details about the items below.



Controls

(The Drawing Area)
is used to interactively modify colormaps. You can use the notion of anchor points to interpolate linearly between two defined anchor points. The colors at the top of the dialog box allow you to preview the colormap that is being defined. The black bar and white squares below the colors allow you to set, delete, and modify anchor points.

Color
specifies color components for the currently selected anchor point.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Color Space
gives you a choice of selecting the color specification.

RGB
enables the specification of colors based on their red, green, and blue components.

HSV
enables the specification of colors based on their hue, saturation, and value.

Red, Green, Blue
are scales with which you can specify the RGB components of the selected anchor color. These scales will appear when **RGB** is selected.

Hue, Saturation, Value
are scales with which you can specify the HSV components of the selected anchor color. These scales will appear when **HSV** is selected.

Colormap
lists colormap names and the name of the colormap being edited.

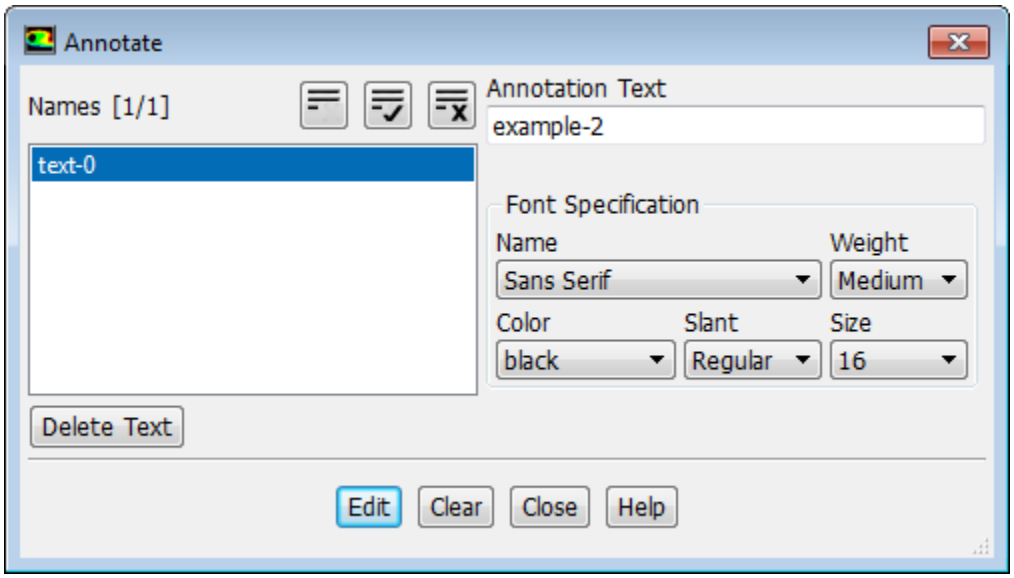
Name
sets the name of the colormap being edited/selected. You can rename existing colormaps and provide names for new colormaps.

Currently Defined
contains a drop-down list of all pre-defined colormaps and all custom colormaps defined by you. You can select a colormap to be modified from this list.

Colormap Size
specifies the number of distinct colors in the colormap. You may specify from 2 to 100 colors.

37.19.32. Annotate Dialog Box

You can use the **Annotate** dialog box to add text with optional attachment lines to the graphics windows, or to modify existing text. See Adding Text Using the Annotate Dialog Box (p. 1790) for details about the items below.



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Names
contains a selectable list of all annotation text strings that have been defined. You can choose a text string to be deleted or edited.

Delete Text
deletes the text strings selected in the **Names** list from the display.

Annotation Text
contains the annotation text string you want to add, or the annotation text string for the item selected in the **Names** list.

Font Specification
contains controls for defining or modifying the font in the annotation text string.

Name
contains a drop-down list of various font styles.

Weight
contains a drop-down list from which you can select **Medium** or **Bold**.

Color
contains a drop-down list of colors that can be used for the text.

Slant
contains a drop-down list from which you can select **Regular** or **Italic** as the slant type.

Size
contains a drop-down list of font sizes (in points).

Add
adds the current **Annotation Text** to the active graphics window. A dialog box will prompt you to select a screen location using the mouse-probe button on your mouse (see Controlling the Mouse Button Functions (p. 1800) for more information on setting the mouse buttons).

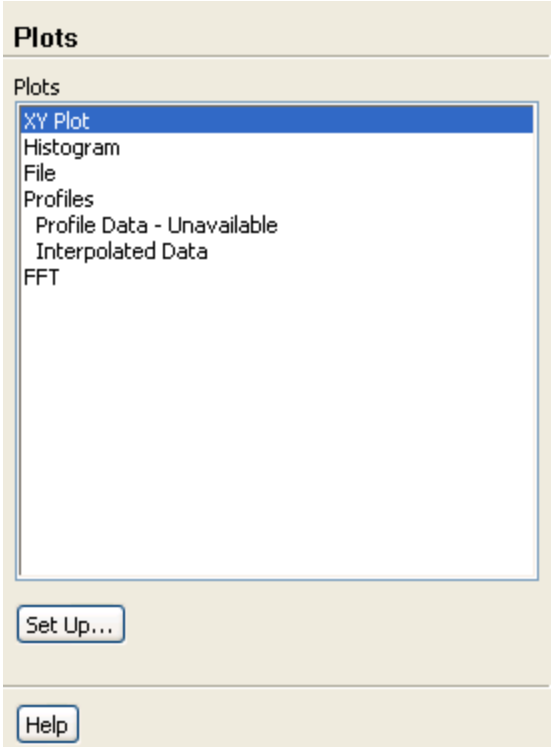
Edit
updates the edited text in the active graphics window. This button will replace the **Add** button when you are editing an existing text string from the **Names** list.

Clear
removes all annotation text and attachment lines from the active graphics window.

37.20. Plots Task Page

The **Plots** task page allows you to create plots (XY, histograms, profiles, and so on) of your computational results. See Displaying Graphics (p. 1747) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Plots
contains a listing of the various plot types available in ANSYS Fluent.

You can double-click an item in the **Plots** list to open the corresponding dialog box, or you can select the item in the list and click the **Set Up...** button.

XY Plot
selecting this item and clicking the **Set Up...** button opens the Solution XY Plot Dialog Box (p. 2595).

Histogram
selecting this item and clicking the **Set Up...** button opens the Histogram Dialog Box (p. 2598).

File
selecting this item and clicking the **Set Up...** button opens the File XY Plot Dialog Box (p. 2599).

Profiles
two types of profile plots are available:

Profile Data
selecting this item and clicking the **Set Up...** button opens the Plot Profile Data Dialog Box (p. 2601).

Interpolated Data
selecting this item and clicking the **Set Up...** button opens the Plot Interpolated Data Dialog Box (p. 2601).

FFT
selecting this item and clicking the **Set Up...** button opens the Fourier Transform Dialog Box (p. 2602).

Set Up...
displays the dialog box corresponding to the selected item in the **Plots** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For additional information, see the following sections:

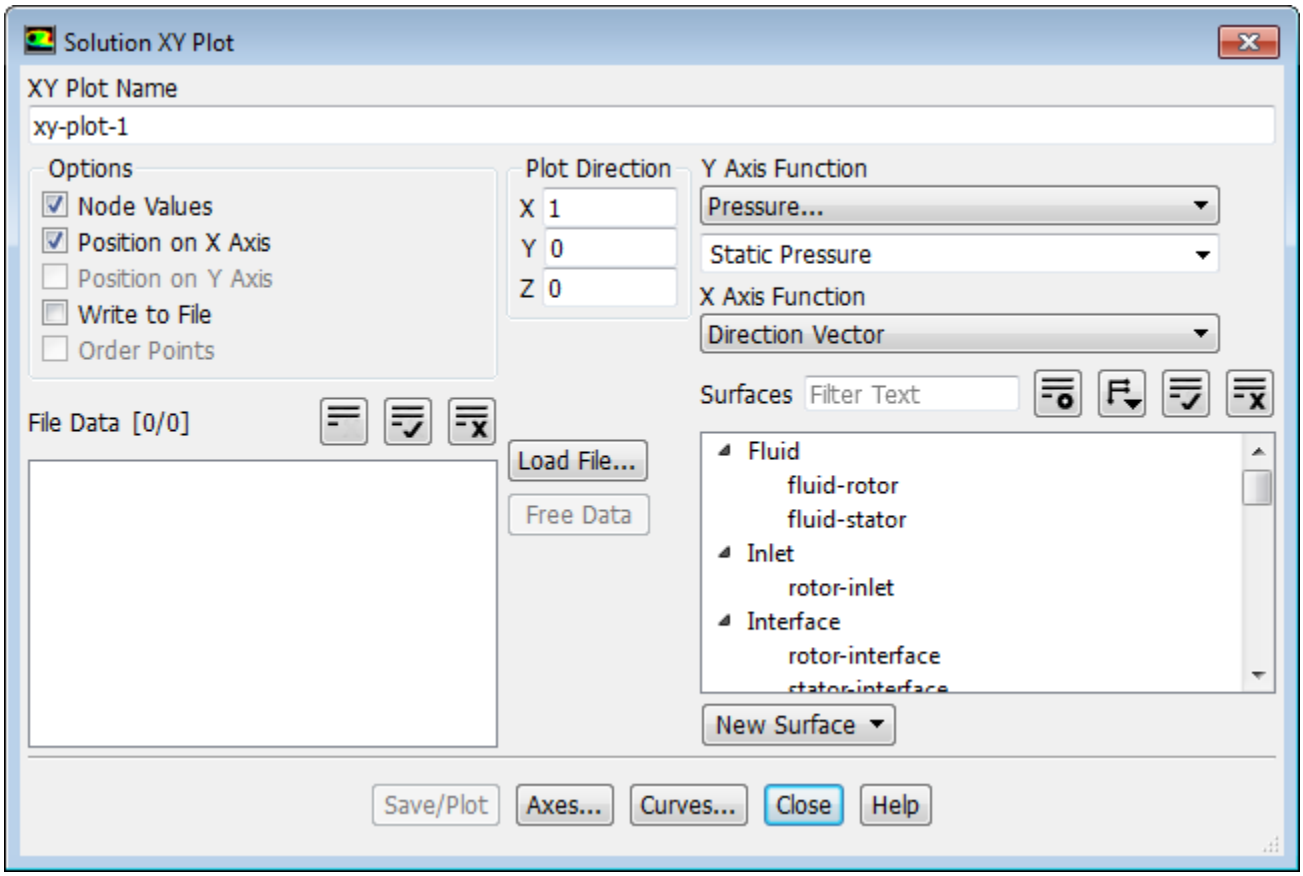
37.20.1. Solution XY Plot Dialog Box
37.20.2. Histogram Dialog Box
37.20.3. File XY Plot Dialog Box
37.20.4. Plot Profile Data Dialog Box
37.20.5. Plot Interpolated Data Dialog Box
37.20.6. Fourier Transform Dialog Box
37.20.7. Plot/Modify Input Signal Dialog Box
37.20.8. Axes Dialog Box
37.20.9. Curves Dialog Box

37.20.1. Solution XY Plot Dialog Box

The **Solution XY Plot** dialog box allows you to display zone, surface and file data in an XY plot format. See Steps for Generating Solution XY Plots (p. 1840) for details about the items below.

*You can also access the **Solution XY Plot** dialog box through the **Postprocessing** ribbon tab.*

Postprocessing → Plots → XY Plot → New...



Controls

XY Plot Name

is the name for a solution XY plot definition. You can specify a name or use the default name **xy-plot-*id***. This control appears only for solution XY plot definitions.

Options

contains check buttons that control the presentation of node or cell-averaged values, the selection of axis functions, and the ability to write the plot data to a file.

Node Values

toggles the node averaging of the data presented in the plot. If the option is inactive, cell values are presented. See Choosing Node or Cell Values (p. 1844) for details.

Position on X Axis, Position on Y Axis

set the x-axis or y-axis function to be the position. If one of these options is turned on, the other will automatically be turned off. You can turn both options off to generate a plot of one flow-field function vs. another, selecting the function for each axis using the **X Axis Function** and **Y Axis Function** drop-down lists.

Write to File

activates the file-writing option. When this option is selected, the **Plot** push button will change to **Write...**. Clicking on the **Write...** button will open the **Select File** dialog box (The Select File Dialog Box (p. 19) and The Select File Dialog Box (Windows) (p. 19)), in which you can specify a name and save a file containing the plot data. The format of this file is described in XY Plot File Format (p. 1850).

Order Points

specifies that plot data being saved to a file should be sorted in order of ascending x axis value. This option is available only when the **Write to File** option is turned on.

Plot Direction

contains inputs for defining the plot direction.

If **Direction Vector** (the default) is selected in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis), the inputs are the components of the direction vector. The position axis of the plot will have coordinate values that correspond to the dot product of the data coordinate vector with the plot direction vector. See Steps for Generating Solution XY Plots (p. 1840) for details.

X

is the component in the x direction.

Y

is the component in the y direction.

Z

is the component in the z direction.

If **Curve Length** is selected in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis), the inputs are the direction along the length of the surface selected in the **Surfaces** list. See Steps for Generating Solution XY Plots (p. 1840) for details.

Default

specifies the plot direction as the direction of increasing curve length.

Reverse

specifies the plot direction as the direction of decreasing curve length.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Show
displays the selected surface in the graphics window, marking the start of the surface with a blue dot and the end of the surface with a red dot. ANSYS Fluent will also display arrows on the surface showing the direction in which the variable will be plotted.

Y Axis Function, X Axis Function
contain lists of solution variables that can be used for the y or x axis of the plot. If the **Position on X Axis** option is turned on, **X Axis Function** will become a single drop-down list, containing two options: **Direction Vector** (to plot the selected variable as a function of position along a specified direction vector) and **Curve Length** (to plot the selected variable as a function of position along the length of a specified curvilinear surface). See Steps for Generating Solution XY Plots (p. 1840) for details.

Likewise, if **Position on Y Axis** is turned on, **Y Axis Function** will become a single drop-down list containing **Direction Vector** and **Curve Length**. If both **Position on X Axis** and **Position on Y Axis** are turned off, you can select field functions for both axes using the **X Axis Function** and **Y Axis Function** lists.

File Data
is a selectable list of the plot titles associated with the loaded external data files. You may choose any number of files for the data plot. The files are loaded using the **Load File...** push button. The format of these files is presented in XY Plot File Format (p. 1850). See Including External Data in the Solution XY Plot (p. 1844) for details.

Load File...
opens the **Select File** dialog box (The Select File Dialog Box (p. 19)), in which you can select the plot file to be read. See Including External Data in the Solution XY Plot (p. 1844) for details. After the external file is loaded, its plot title will be displayed in the **File Data** list.

Free Data
removes the files selected in the **File Data** list.

Surfaces
is a selectable list of surfaces in the solution domain. You may choose any number of surfaces for the data plot.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plot
plots the specified surface and/or file data in the active graphics window using the current axis and curve attributes. If the **Write to File** option is turned on, this button becomes the **Write...** button.

Write...
opens the **Select File** dialog box (The Select File Dialog Box (p. 19)), in which you can save the plot data to a file. This button replaces the **Plot** button when the **Write to File** option is turned on.

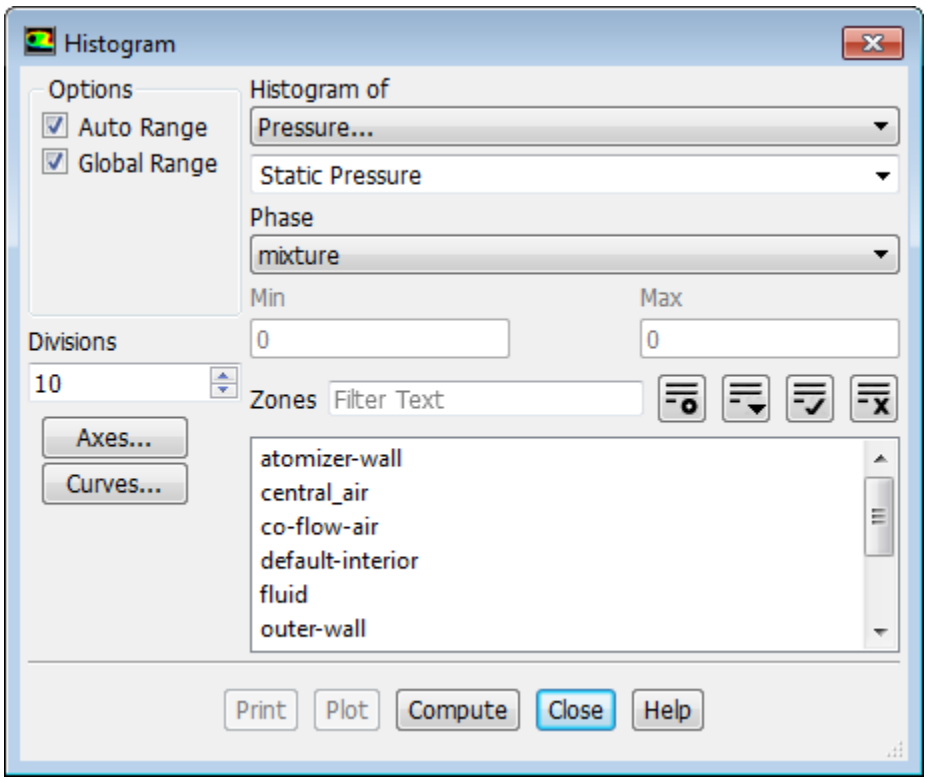
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot.

Save/Plot
plots the specified surface and/or file data in the active graphics window using the current axis and curve attributes and saves the XY plot definition. This button appears only for solution XY plot definitions and replaces the **Plot** button.

37.20.2. Histogram Dialog Box

The **Histogram** dialog box allows you to create histograms of selected geometric or physical data. See Steps for Generating Histogram Plots (p. 1851) for details about the items below.



Controls

Options
contains the check buttons for current histogram options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Auto Range
toggles the ability to specify the minimum and maximum range of scalar values in the histogram print or plot. If the option is not active, the **Min** and **Max** fields are editable, and you may specify the desired range. If the option is active, the range is defined by the minimum and maximum values in the computational domain.

Global Range
toggles the ability to specify the minimum and maximum values on the range of values on the selected surfaces, rather than in the entire domain.

Divisions
sets the number of data intervals that will exist in the histogram.

Zone Types
contains a list of available face or cell zone types.

Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the histogram plot.

Histogram of
contains a list of scalar quantities that can be used in the histogram.

Min
displays or allows definition of the minimum value of the selected scalar quantity used in the histogram.

Max
displays or allows definition of the maximum value of the selected scalar quantity used in the histogram.

Zones
contains a list of available face or cell zones.

Print
displays the histogram interval.

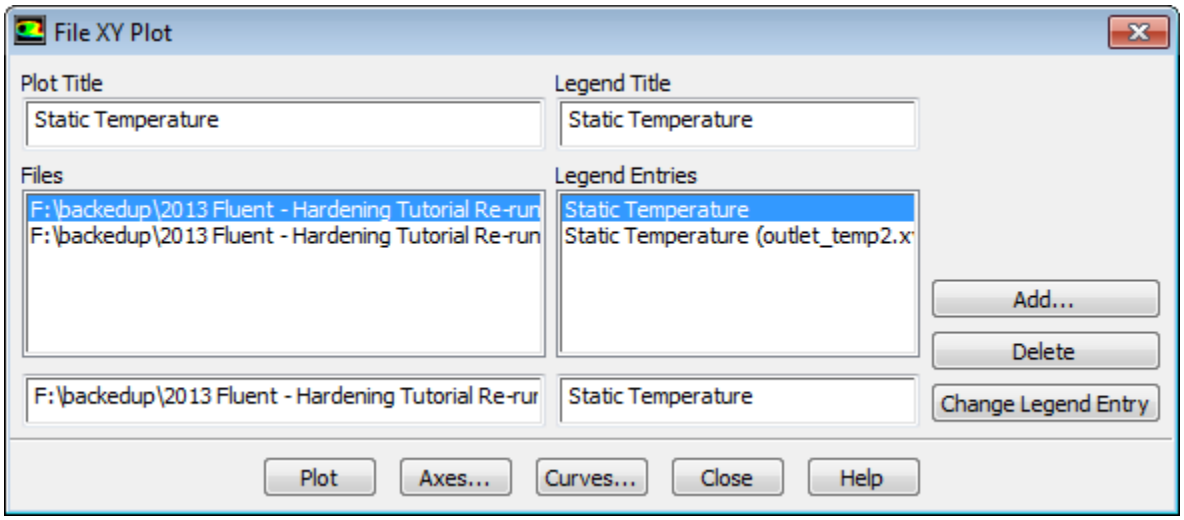
Plot
displays a plot of the percentage of the total number of cells versus the scalar quantity in the active graphics window.

Compute
computes the minimum and maximum cell values of the selected scalar quantity. The values are displayed in **Min** and **Max**.

37.20.3. File XY Plot Dialog Box

The **File XY Plot** dialog box allows you to display data read from one or more files in an abscissa/ordinate plot form. The format of the plot file is described in XY Plot File Format (p. 1850). See Steps for Generating XY Plots of Data in External Files (p. 1844) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Plot Title

displays the current plot title. The default plot title is the y-axis label of the first file read into the dialog box, but you can edit the text entry to change the plot title.

Files

contains a selectable list of loaded file names. If you enter a valid file name into the text entry field below the list and click the **Add...** button ANSYS Fluent will load the file and update the dialog box. If, however, the file is not found or has already been read, The Select File Dialog Box (p. 19) will be opened.

Legend Title

sets the title of the legend. By default, the legend has no title.

Legend Entries

contains a selectable list of legend labels associated with the loaded files. The default legend label is the title (first string) in the file. You can modify the legend label by selecting the old name in the **Legend Entries** list. It is then displayed in the text entry field below the list and may be edited.

Add...

loads the file named in the **Files** text entry field or opens the **Select File** dialog box if no name, a wrong name, or a duplicate name appears in that text field.

Delete

removes the file selected in the **Files** list.

Change Legend Entry

changes the legend label of the selected file to the text entered in the text entry field below the **Legend Entries** list.

Plot

displays an XY plot of the data associated with every loaded file. You can use the **Delete** button to remove files that you do not want to plot.

Axes...

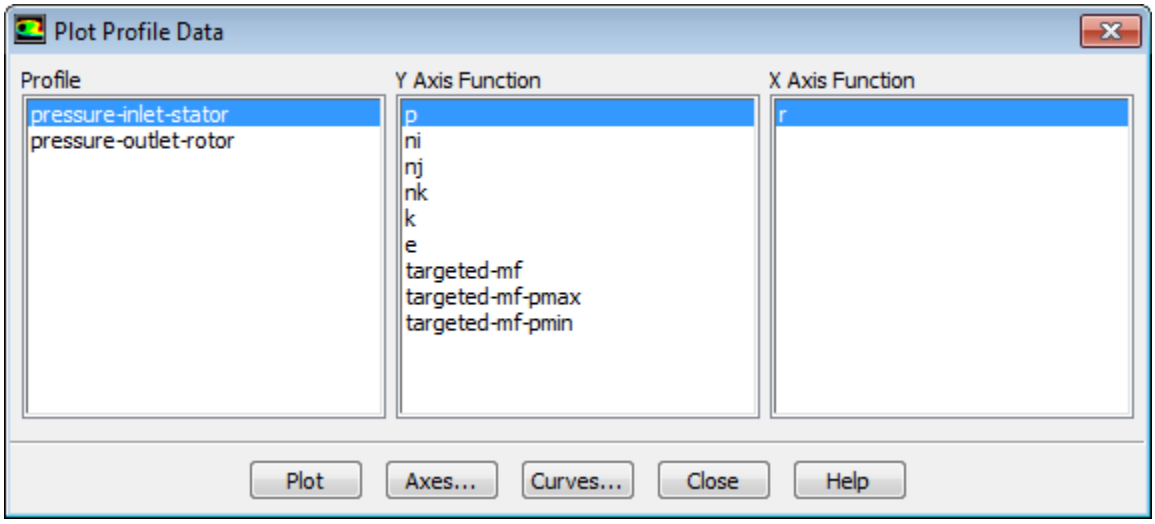
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot.

37.20.4. Plot Profile Data Dialog Box

The **Plot Profile Data** dialog box allows you to display an XY plot of the original data points of a boundary profile before it is interpolated onto the cell faces of a boundary. See Steps for Generating Plots of Profile Data (p. 1846) for details about the items below.



Controls

Profile
contains a selectable list of available profiles. When a profile is selected its available fields are displayed under **Y Axis Function**.

Y Axis Function
contains a selectable list of the fields available in the selected profile that can be used for the y axis of the plot.

X Axis Function
contains a selectable list of the variables that can be used for the x axis of the plot.

Plot
displays an XY plot of the data points from the selected profile.

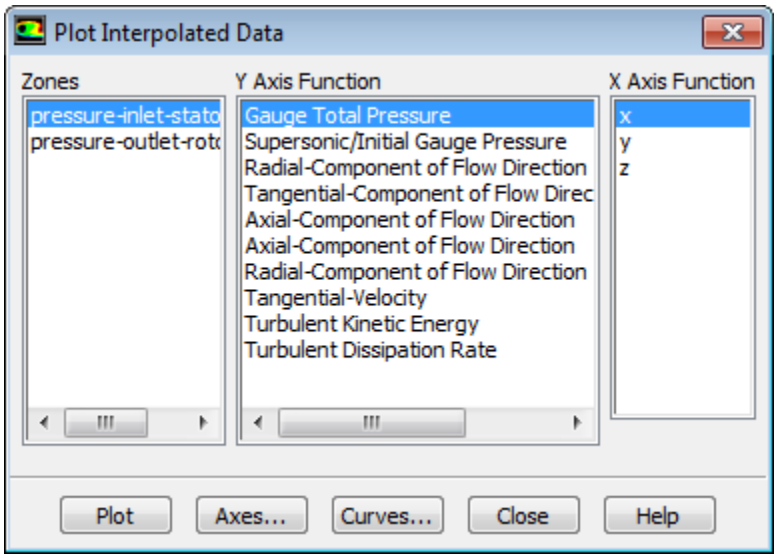
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot.

37.20.5. Plot Interpolated Data Dialog Box

The **Plot Interpolated Data** dialog box allows you to display an XY plot of the values assigned to the cell faces when a profile file has been interpolated on a boundary. See Steps for Generating Plots of Interpolated Profile Data (p. 1847) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Zones
contains a selectable list of the zones for which a profile field has been set as one or more of the parameters are displayed under **Y Axis Function**.

Y Axis Function
contains a selectable list of the profile-related parameters in the selected zone that can be used for the y axis of the plot. The name of the parameter will be the same as that of the drop-down list in the boundary condition dialog box from which the profile field was selected.

X Axis Function
contains a selectable list of the geometry variables that can be used for the x axis of the plot.

Plot
displays an XY plot of the cell face values (as interpolated from the data points of the profile file) of the selected zone.

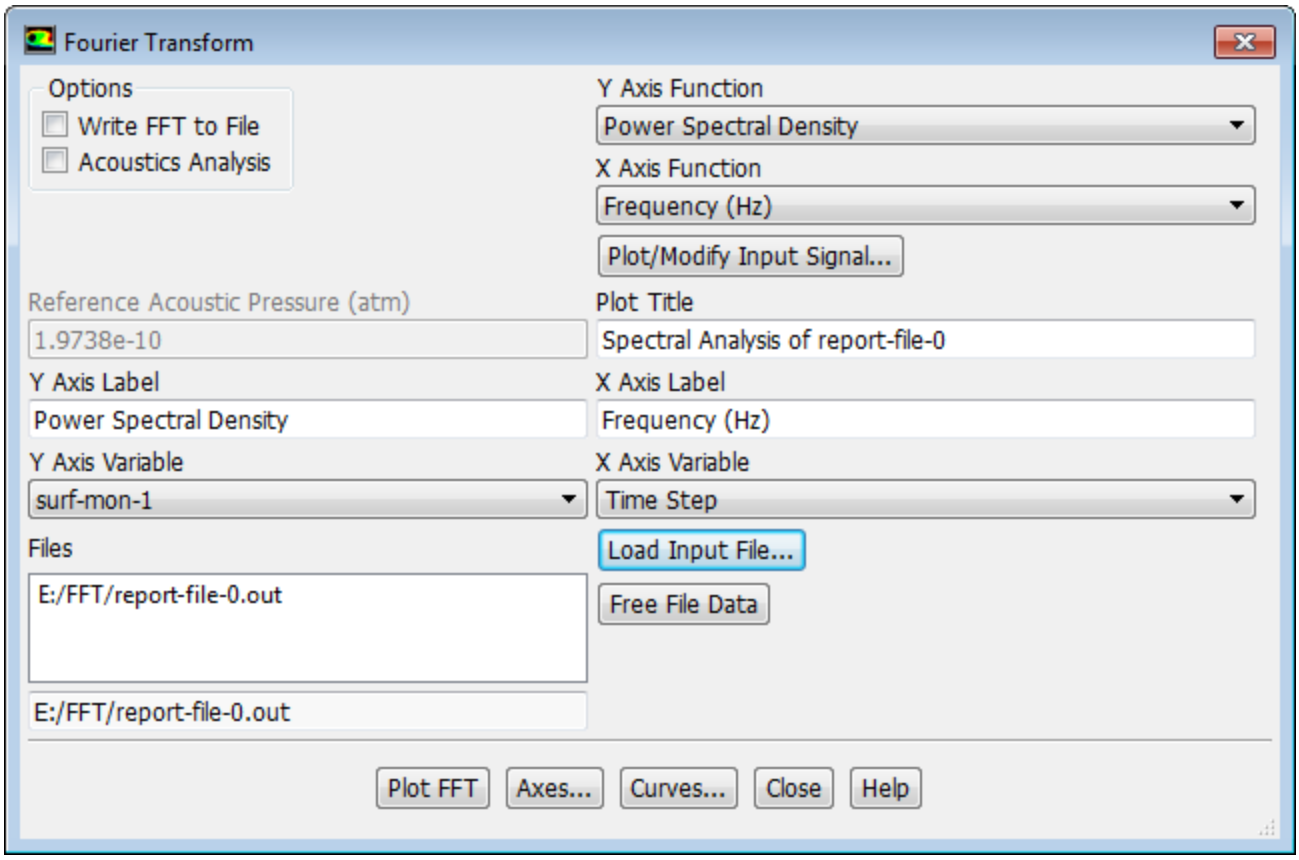
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot.

37.20.6. Fourier Transform Dialog Box

The **Fourier Transform** dialog box allows you to analyze your time dependent data using the Fast Fourier Transform (FFT) algorithm. See Fast Fourier Transform (FFT) Postprocessing (p. 1873) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
lets you write the FFT data to a file or display the FFT data in a graphics window.

Write FFT to File
allows you to write out the FFT data directly to a file. When selected, the **Plot FFT...** buttons becomes the **Write FFT...** button.

Acoustics Analysis
enables the acoustics-relevant spectrum options (sound pressure level spectra and frequency band charts), and specifies that the overall sound pressure level is calculated and displayed in the console when you plot or write the FFT data. All dB-measured quantities are based on the **Reference Acoustic Pressure**.

Process Options
contains options to analyze signal data.

Process Receiver
allows you to analyze receiver data stored in memory.

Process File Data
allows you to analyze signal data from an existing input file.

Y Axis Function
contains a list from which you can select the function for the y axis.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

X Axis Function
contains a list from which you can select the function for the x axis.

Receiver
contains a list of receivers from which you can select when the **Process Receiver** option is enabled.

Plot/Modify Input Signal...
opens the Plot/Modify Input Signal Dialog Box (p. 2605), which you can use to plot the input signal, as well as customize the data set and define spectrum smoothing in preparation for applying the FFT algorithm.

Reference Acoustic Pressure
allows you to specify the reference acoustic pressure (for example, p_{ref} in Equation 31.41 (p. 1880)) used to calculate the dB-measured quantities when the **Acoustics Analysis** option is enabled.

Plot Title
lets you create a new title or edit the original title for the FFT plot. By default, ANSYS Fluent adds the string "Spectral Analysis of" to the title originally applied to the input signal plot.

Y Axis Label
allows you to create a new y axis label or edit the original y axis label. By default, the **Y Axis Label** corresponds to the selection in the **Y Axis Function** drop-down list.

X Axis Label
allows you to create a new x axis label or edit the original x axis label. By default, the **X Axis Label** corresponds to the selection in the **X Axis Function** drop-down list.

Y Axis Variable
if your input report file contains multiple report definitions, this allows you to specify the y axis variable.

X Axis Variable
if your input report file contains multiple report definitions, this allows you to specify the x axis variable.

Files
lists the loaded input signal data files.

Load Input File...
loads an input signal data file into ANSYS Fluent for FFT analysis. The input file is listed under **Files**.

Free File Data
removes data from FFT analysis once the input signal data file is selected in the **Files** list.

Plot FFT
displays the FFT data in a graphic window and, if **Acoustics Analysis** is enabled, calculates the overall sound pressure level in dB (based on the **Reference Acoustic Pressure**) and displays it in the console. If the **Write FFT to File** option is selected, then this button becomes the **Write FFT** button, which opens a file selection dialog box so that you write the FFT data to a file.

Write FFT
opens The Select File Dialog Box (p. 19) in which you can specify a name and save the FFT data to a file. If **Acoustics Analysis** is enabled, the overall sound pressure level will be calculated in dB (based on the **Reference Acoustic Pressure**) and displayed in the console at this time. If the **Write FFT to File** option is selected, then the **Plot FFT** button changes to the **Write FFT** button.

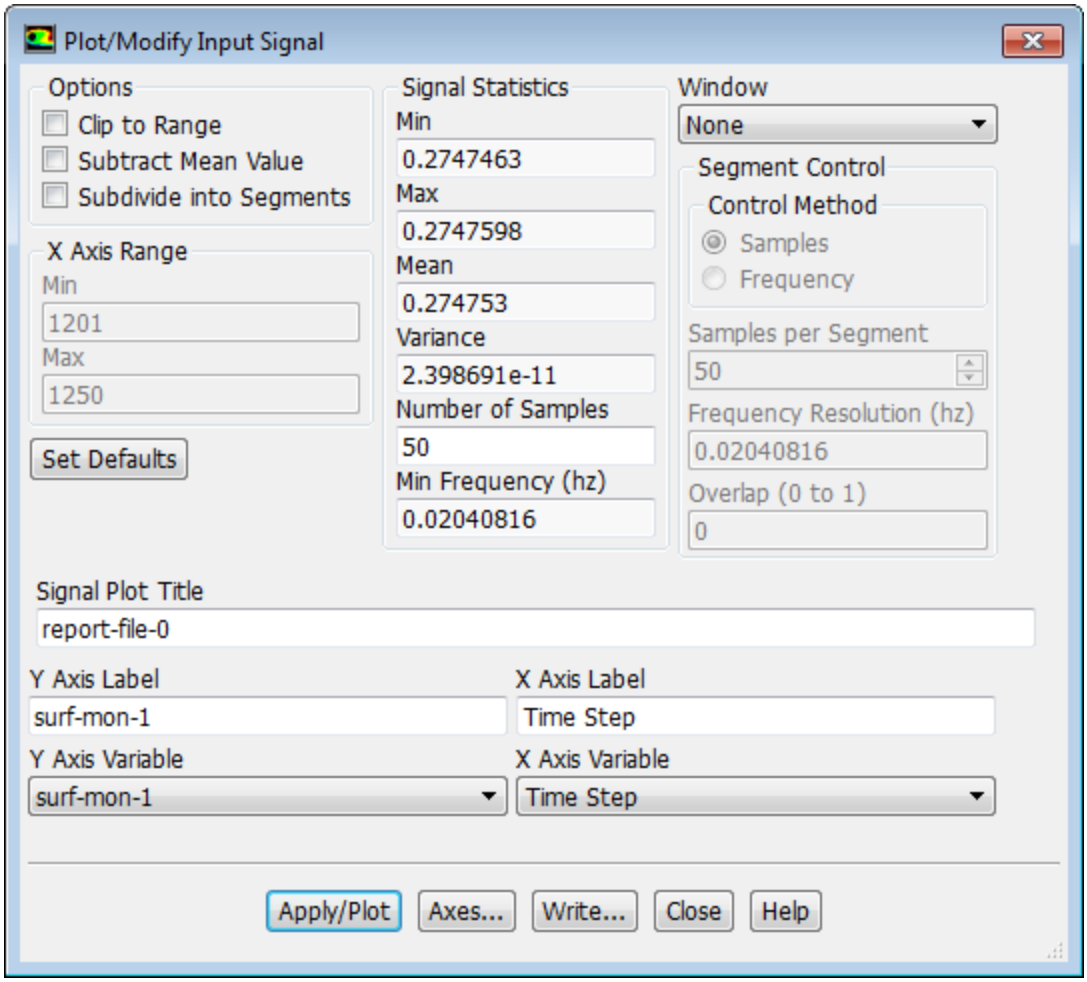
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the plot.

37.20.7. Plot/Modify Input Signal Dialog Box

The **Plot/Modify Input Signal** dialog box allows you to plot the input signal, as well as customize the data set and define spectrum smoothing in preparation for applying the FFT algorithm. It is opened from the Fourier Transform Dialog Box (p. 2602). See Using the FFT Utility (p. 1875) for details about the items below.



Controls

Options
allows you to process some or all of the input signal data.

Clip to Range
allows you to analyze a portion of the input signal by specifying data range.

Subtract Mean Value
reduces y axis quantities by the mean value of the relevant signal property.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Subdivide into Segments
enables / disables spectrum smoothing, which can suppress spurious amplitude fluctuations in the Fourier spectrum by splitting the input signal into multiple overlapping segments, so that ANSYS Fluent can apply the FFT algorithm on each segment and then average the resulting spectra. The spectrum smoothing is controlled by the settings in the **Segment Control** group box. See Customizing the Input and Defining the Spectrum Smoothing (p. 1877) for further details.

Signal Statistics
displays signal information.

Min
displays the minimum value for the input signal.

Max
displays the maximum value for the input signal.

Mean
displays the average value for the input signal.

Variance
displays the variance for the input signal.

Number of Samples
displays the total number of samples in the input signal data set.

Min Frequency
displays the finest possible frequency resolution for the input signal.

X Axis Range
allows for a portion of the input signal to be analyzed when the **Process the whole data** option is turned off.

Min
specifies a minimum value for the x axis.

Max
specifies a maximum value for the x axis.

Set Defaults
resets the x axis minimum and maximum values to their original value and turns on the **Process the whole data** option.

Signal Plot Title
lets you create a new title or edit the original title for the input signal plot. By default, the **Signal Plot Title** corresponds with the title originally applied to the input signal plot.

Y Axis Label
allows you to create a new y axis label or edit the original y axis label. By default, the **Y Axis Label** corresponds with the y axis label originally applied to the input signal plot.

X Axis Label
allows you to create a new x axis label or edit the original x axis label. By default, the **X Axis Label** corresponds with the x axis label originally applied to the input signal plot.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Y Axis Variable
if your input report file contains multiple report definitions, this allows you to specify the y axis variable.

X Axis Variable
if your input report file contains multiple report definitions, this allows you to specify the x axis variable.

Window
lets you specify a windowing technique to remove discontinuities in the FFT calculation.

None
applies no windowing technique. This is the default setting.

Hamming
applies the Hamming technique.

Hanning
applies the Hanning technique.

Barlett
applies the Barlett technique.

Blackman
applies the Blackman technique.

Segment Control
provides settings that control the spectrum smoothing when **Subdivide into Segments** is enabled.

Control Method
allows you to specify how you want to define the segment size from the following:

Samples
bases the segment size on the **Samples per Segment**.

Frequency
bases the segment size on the **Frequency Resolution** Δf in Hertz units.

Samples per Segment
defines the number of samples in each segment when **Samples** is selected from the **Control Method** list.

Frequency Resolution
defines the desired frequency resolution Δf in Hertz units when **Frequency** is selected from the **Control Method** list.

Overlap
ranges from 0 to 1 and defines how much adjacent segments overlap. This setting is applicable regardless of which **Control Method** you select.

Apply/Plot
applies any changes you have made in the dialog box and displays the input signal data in a graphics window.

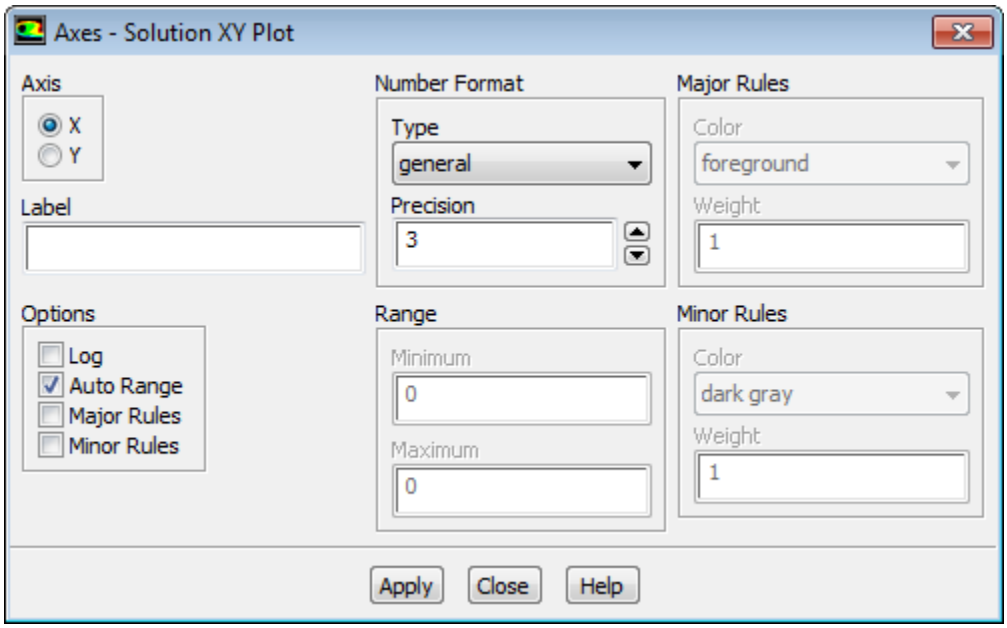
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the plot axes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Write...
opens The Select File Dialog Box (p. 19), in which you can save the signals to a file.

37.20.8. Axes Dialog Box

The **Axes** dialog box allows you to independently control the characteristics of the ordinate and abscissa on an XY plot or histogram. You can change the labels, scale, range, number format, and major and minor rules visibility and appearance. Note that the title following **Axes** in the dialog box indicates which plot environment you are changing. You can set different parameters for each type of plot that ANSYS Fluent can generate. See Using the Axes Dialog Box (p. 1853) for details about the items below.



Controls

Axis
contains check buttons that allow you to set abscissa (x-axis) or ordinate (y-axis) characteristics.

X
allows you to specify the abscissa characteristics.

Y
allows you to specify the ordinate characteristics.

Label
defines the character string that will label the active axis (the one selected in **Axis**) in the display.

Options
contains check buttons that (de)activate scale, range, major rules, and minor rules.

Log
toggles logarithmic scaling of the active axis. By default, decimal scaling is used.

Auto Range
toggles automatic computation of the range of the active axis. If you deactivate this option, you may input the **Minimum** and **Maximum** values in the **Range** box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Major Rules
toggles the display of major rules on the active axis. Major rules are the horizontal or vertical lines that mark the primary data divisions and span the whole plot window to produce a "grid."

Minor Rules
toggles the display of minor rules on the active axis. Minor rules are the horizontal or vertical lines that mark the secondary data divisions and span the whole plot window to produce a "grid."

Number Format
contains controls for changing the format of the data labels on the active axis. Data labels are the character strings used to define the primary data divisions on the axes.

Type
sets the form of the data labels. You may select from a drop-down list of options, including the following:

general
displays the real value with either float or exponential form based on the size of the number and the defined **Precision**.

float
displays the real value with an integral and fractional part (for example, 1.0000), where the number of digits in the fractional part is determined by **Precision**.

exponential
displays the real value with a mantissa and exponent (for example, 1.0e-02), where the number of digits in the fractional part of the mantissa is determined by **Precision**.

Precision
defines the number of fractional digits displayed in the data labels.

Range
contains the range or extents of the active axis. To set the range manually, you must turn off **Auto Range**. Otherwise the extents are computed automatically.

Minimum
sets the minimum data value for the active axis.

Maximum
sets the maximum data value for the active axis.

Major Rules
contains controls for modifying the appearance of the major rules. To use these controls you must activate **Major Rules** in the **Options** list.

Color
sets the color of the major rules from a drop-down list with numerous color selections.

Weight
sets the line thickness of the major rule. A line of weight 1.0 is normally 1 pixel wide. A weight of 2.0 would make the line twice as thick (2 pixels wide).

Minor Rules
contains controls for modifying the appearance of the minor rules. To use these controls you must activate **Minor Rules** in the **Options** list.

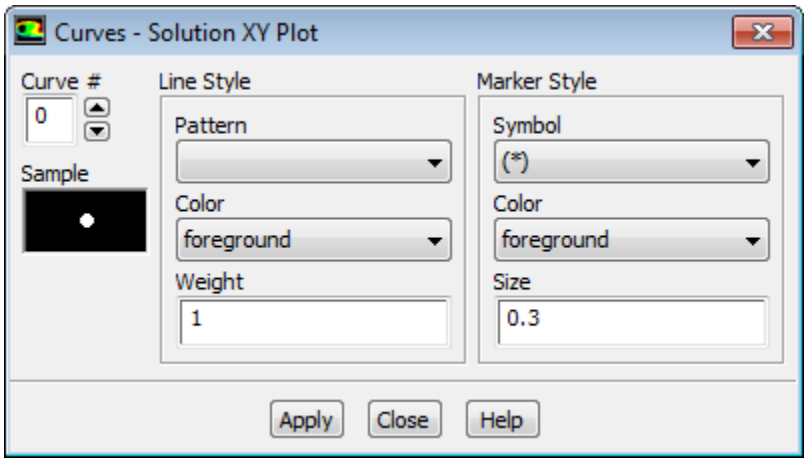
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Color
sets the color of the minor rules from a drop-down list with numerous color selections.

Weight
sets the line thickness of the minor rule. A line of weight 1.0 is 1 pixel wide. A weight of 2.0 would make the line twice as thick (2 pixels wide).

37.20.9. Curves Dialog Box

The **Curves** dialog box allows you to modify the appearance of the lines and markers used in XY plots. Note that the title following **Curves** in the dialog box indicates which plot environment you are changing. You can set different parameters for each type of plot that ANSYS Fluent can generate. See Using the Curves Dialog Box (p. 1855) for details about the items below.



Controls

Curve #
defines the active curve number. The present and future marker and line styles apply to the defined curve number. The curves are numbered sequentially, starting from 0. For example, if you were plotting flow-field values on two zones, the first zone would be curve 0, and the second, curve 1. If the plot contains only one curve, the **Curve #** is set to 0 and is not editable.

Sample
displays a single marker and line with the current style attributes.

Line Style
contains controls for modifying the appearance of the active curve.

Pattern
sets the pattern of the active curve. A drop-down list allows you to set the line pattern. Except for **center** and **phantom** lines, the list displays examples of the pattern choices. A **center** line alternates a very long dash and a short dash and a **phantom** line alternates a very long dash and a double short dash.

Color
sets the color of the active curve. A drop-down list allows you to select from a list of color names.

Weight
sets the thickness of the active curve. A line weight of 1.0 is normally 1 pixel wide. Therefore, a weight of 2.0 would make the line twice as thick (2 pixels wide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Marker Style
contains controls for modifying the appearance of the active curve's marker.

Symbol
sets the symbol used to mark data. You can select the symbol from a drop-down list that contains all the symbol choices. The **Sample** box will allow you to experiment with various markers. For example, in plotting pressure-coefficient data on the upper and lower surfaces of an airfoil, the symbol /*\ (filled-in upward-pointing triangle) could be used for the marker representing the upper surface data, and the symbol */ (filled-in downward-pointing triangle) could be used for the marker representing the lower surface data.

Color
sets the color of the marker on the active line number. A drop-down list allows you to select from a list of color names.

Size
sets the size of the data marker. A symbol of size 1.0 is 3.0% of the height of the display screen, except for the "." symbol, which is always one pixel.

37.21. Reports Task Page

The **Reports** task page allows you to set up reports for your CFD simulation. Reports can be compiled for fluxes, forces, projected areas, surface and volume integrals, among others. See Reporting Alphanumeric Data (p. 1885) for more information.

Controls

Reports
displays a list of available report types in ANSYS Fluent.

You can double-click an item in the **Reports** list to open the corresponding dialog box, or you can select the item in the list and click the **Set Up...** button.

Fluxes
selecting this item and clicking the **Set Up...** button opens the Flux Reports Dialog Box (p. 2613).

Forces
selecting this item and clicking the **Set Up...** button opens the Force Reports Dialog Box (p. 2614).

Projected Areas
selecting this item and clicking the **Set Up...** button opens the Projected Surface Areas Dialog Box (p. 2615).

Surface Integrals
selecting this item and clicking the **Set Up...** button opens the Surface Integrals Dialog Box (p. 2616).

Volume Integrals
selecting this item and clicking the **Set Up...** button opens the Volume Integrals Dialog Box (p. 2620).

Discrete Phase
allows you to report on one of the following three report types:

Sample
selecting this item and clicking the **Set Up...** button opens the Sample Trajectories Dialog Box (p. 2622).

Histogram
selecting this item and clicking the **Set Up...** button opens the Trajectory Sample Histograms Dialog Box (p. 2623).

Summary
selecting this item and clicking the **Set Up...** button opens the Particle Summary Dialog Box (p. 2625).

Heat Exchanger
selecting this item and clicking the **Set Up...** button opens the Heat Exchanger Report Dialog Box (p. 2625).

Set Up...
opens the dialog box corresponding to the selected item in the **Reports** list.

Parameters...
opens the Parameters Dialog Box (p. 2627).

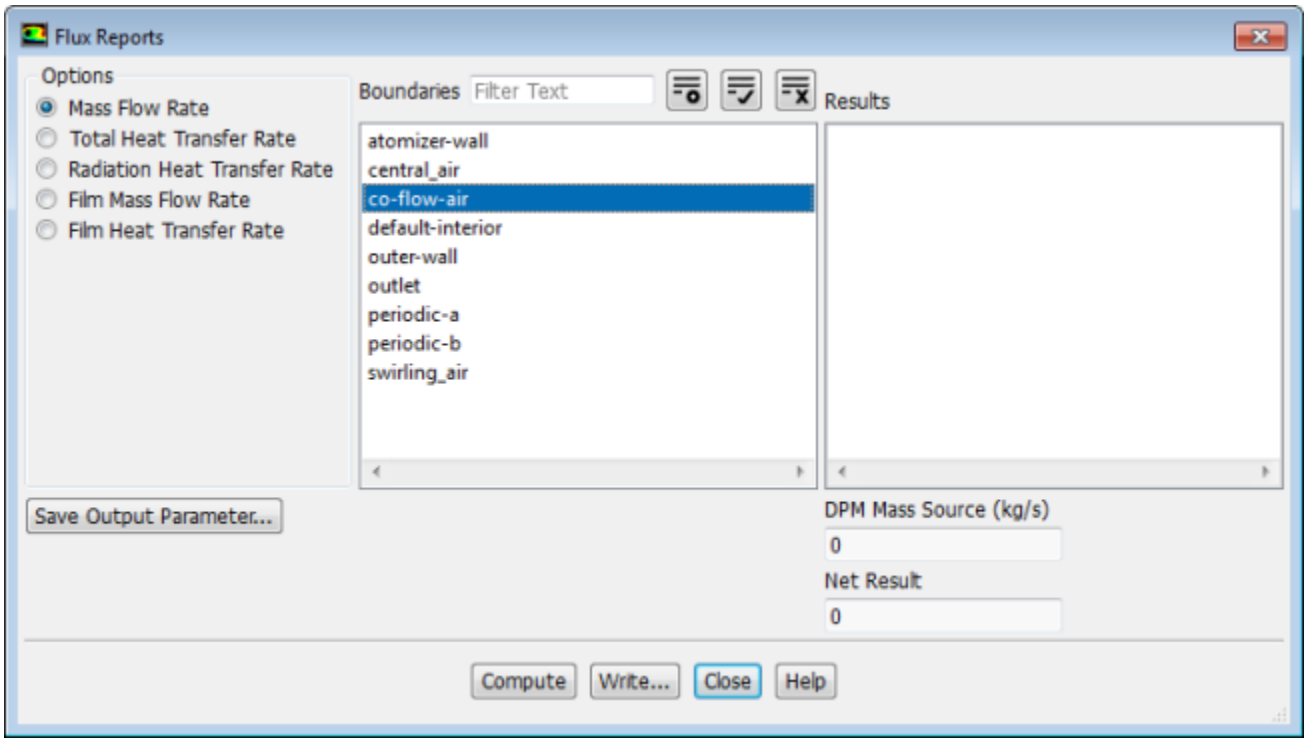
For additional information, see the following sections:
37.21.1. Flux Reports Dialog Box
37.21.2. Force Reports Dialog Box
37.21.3. Projected Surface Areas Dialog Box
37.21.4. Surface Integrals Dialog Box
37.21.5. Volume Integrals Dialog Box
37.21.6. Sample Trajectories Dialog Box
37.21.7. Trajectory Sample Histograms Dialog Box
37.21.8. Particle Summary Dialog Box
37.21.9. Heat Exchanger Report Dialog Box
37.21.10. Parameters Dialog Box
37.21.11. Use Input Parameter in Scheme Procedure Dialog Box
37.21.12. Use Input Parameter for UDF Dialog Box
37.21.13. Rename Dialog Box
37.21.14. Input Parameter Properties Dialog Box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.21.15. Save Output Parameter Dialog Box

37.21.1. Flux Reports Dialog Box

The **Flux Reports** dialog box allows you to compute the mass flow rate, heat transfer rate, and radiation heat transfer rate on selected boundary zones. See Fluxes Through Boundaries (p. 1911) for details.



Controls

Options
contains the following option buttons:

Mass Flow Rate
turns on the computation of the mass flow rate for the selected boundary zones.

Total Heat Transfer Rate
turns on the computation of the total heat transfer rate for the selected boundary zones.

Total Sensible Heat Transfer Rate
turns on the computation of the total sensible heat transfer rate for the selected boundary zones. It reports the total energy flux as defined in Equation 5.2 in the Theory Guide.

Radiation Heat Transfer Rate
turns on the computation of the radiation heat transfer rate for the selected boundary zones.

Film Mass Flow Rate
(available only when the Eulerian wall film model is enabled) turns on the computation of the mass flow rate for the selected boundary zone(s).

Film Heat Transfer Rate
(available only when the Eulerian wall film model is enabled) turns on the computation of the film heat transfer rate for the selected boundary zone(s).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Save Output Parameter...
opens the Save Output Parameter Dialog Box (p. 2631).

Boundaries
contains a selectable list of valid boundary zones for flux reporting.

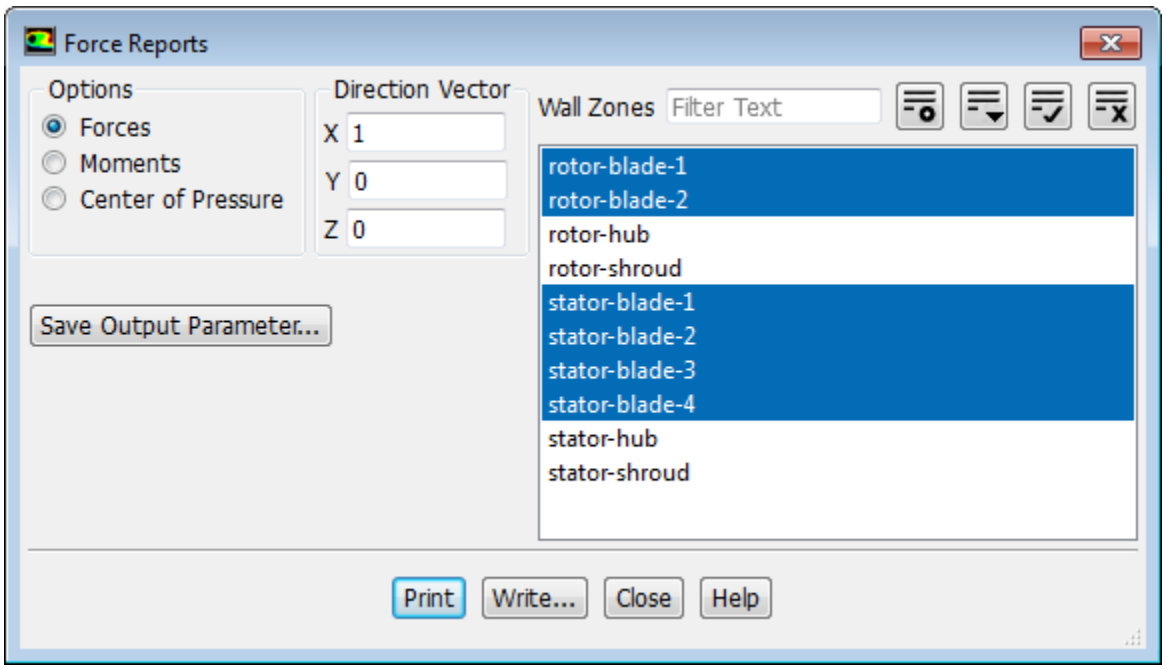
Results
displays the results of the selected flux computation for each boundary zone selected. The summation of the individual zone flux results is displayed in the box below the **Results** list.

Compute
computes the flux for each of the selected boundary zones and updates the **Heat of Reaction Source** and **Net Results** (for example, in kg/s, W, and so on).

Write...
opens the **Select File** dialog box (The Select File Dialog Box (p. 19) and The Select File Dialog Box (Windows) (p. 19)), which you can use to save the reported values to a file.

37.21.2. Force Reports Dialog Box

The **Force Reports** dialog box allows you to compute the forces along a specified vector, moments about a specified center, and the coordinates of the center of pressure for selected wall zones. See Forces on Boundaries (p. 1916) for details.



Controls

Options
contains option buttons that control computation of the forces, moments, or center of pressure.

Forces
enables the computation of the pressure and viscous forces.

Moments
enables the computation of the pressure and viscous moments.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Center of Presure
enables the computation of the average location of the pressure.

Direction Vector
contains the components of the force vector. This label is visible when the **Forces** option button is active.

X,Y,Z
are the components of the force vector along which the forces will be computed.

Moment Center
contains the Cartesian coordinates of the moment center. This label is visible when the **Moments** option button is active.

X,Y,Z
are the Cartesian coordinates of the moment center about which moments will be computed.

Moment Axis
contains the Cartesian coordinates of the moment axis. This label is visible when the **Moments** option button is active.

X,Y,Z
are the Cartesian coordinates of the moment axis about which moments will be computed.

Coordinate
contains the value of the Cartesian coordinate that is fixed. This label is visible when the **Center of Pressure** option button is active.

X,Y,Z
are the Cartesian coordinates, one of which will be fixed.

Value (n)
is the point where the selected Cartesian coordinate will be fixed.

Wall Zones
contains a selectable list of wall zones. The force or moment information is printed for each zone, and then a total force or moment for all the zones is presented.

Save Output Parameter...
opens the Save Output Parameter Dialog Box (p. 2631).

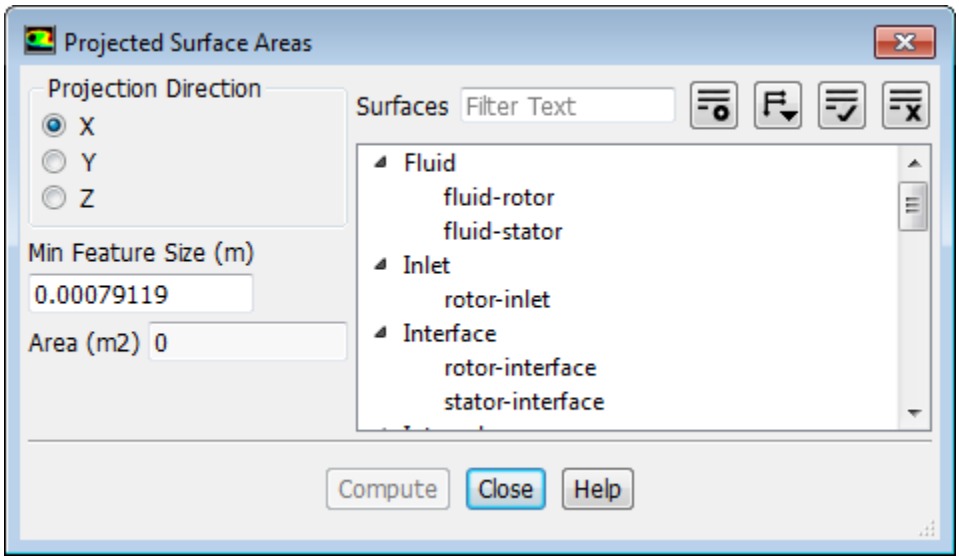
Print
displays (in the console) the pressure, viscous (if appropriate), and total forces or moments, and the pressure, viscous, and total force coefficients along the specified force vector or moment center for the selected wall zones. The center of pressure coordinates will print to the console when the **Center of Pressure** option is activated.

Write...
opens The Select File Dialog Box (p. 19), which you can use to save the reported values to a file.

37.21.3. Projected Surface Areas Dialog Box

The **Projected Surface Areas** dialog box allows you to compute an estimated area of the projection of selected surfaces along the x, y, or z axis. See Projected Surface Area Calculations (p. 1919) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Projection Direction
indicates the direction along which to project the surface.

Min Feature Size
specifies the length of the smallest feature in the geometry that you want to resolve in the area calculation.

Area
displays the computed projected area.

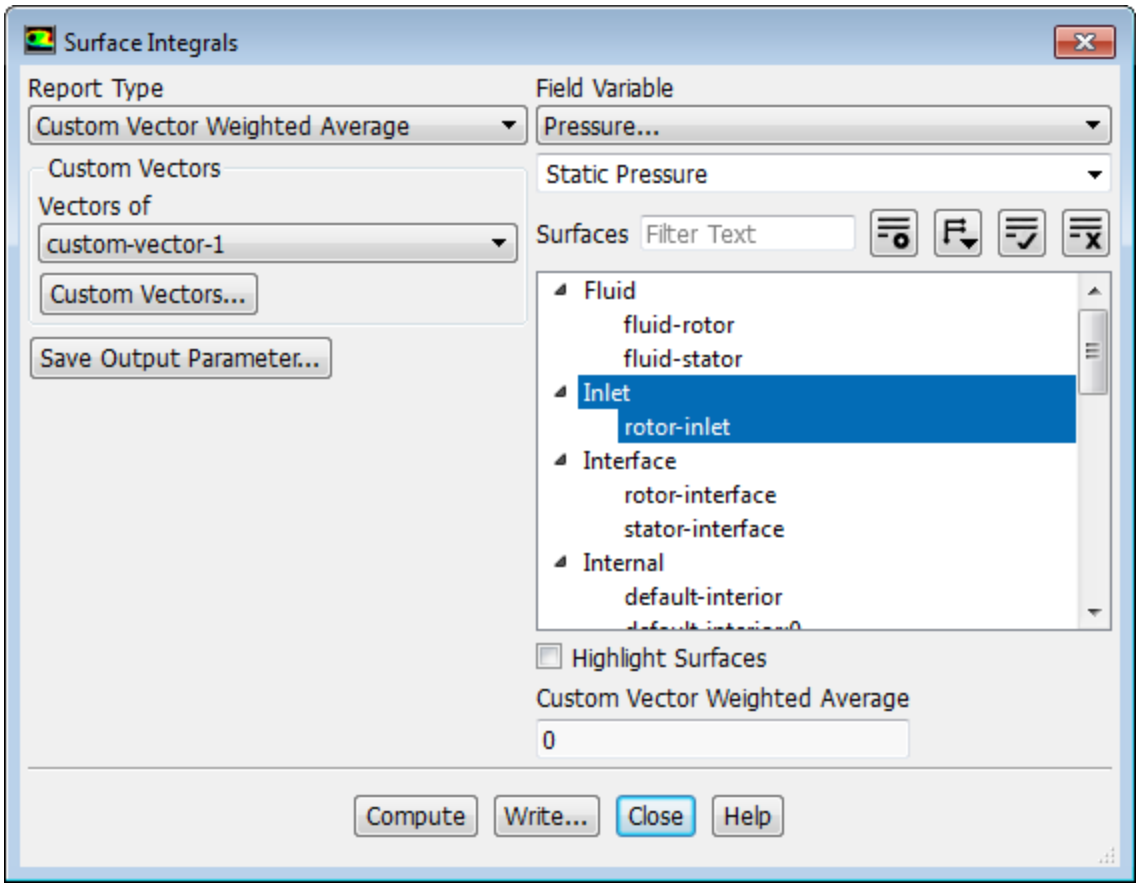
Surfaces
contains a list of existing surfaces. You can select the surface(s) for which the projected area is to be calculated in this list.

Compute
computes the area of the selected surfaces projected along the selected direction. The area will be printed in the **Area** box and in the console window.

37.21.4. Surface Integrals Dialog Box

The **Surface Integrals** dialog box allows you to compute the area, mass and volume flow rate, standard deviation, integral, flow rate, area-weighted average, custom vector-based flux, custom vector flux, custom vector-weighted average, mass-weighted average, sum, facet average, facet minimum/maximum, uniformity index (weighted by area or mass), vertex average, or vertex minimum/maximum quantity of a specified field variable on a selected list of surfaces. See Surface Integration (p. 1920) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Report Type
contains drop-down list that has options that control the method of surface integration.

Area
turns on the computation of the surface area.

Area-Weighted Average
turns on the computation of the area-weighted average on the surface(s).

Custom Vector Based Flux
turns on the computation of the vector-based flow rate of a quantity through the surface(s).

Custom Vector Flux
turns on the computation of the flow rate on a vector through the surface(s).

Custom Vector Weighted Average
turns on the computation of vector-weighted average of a quantity on the surface(s).

Facet Average
turns on the computation of the facet-averaged quantity on the surface(s).

Facet Minimum
turns on the computation of the facet minimum of a quantity on the surface(s).

Facet Maximum
turns on the computation of the facet maximum of a quantity on the surface(s).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Flow Rate
turns on the computation of the flow rate through the surface(s).

Integral
turns on the computation of the integral on the surface(s).

Mass Flow Rate
turns on the computation of the mass flow rate through the surface(s).

Mass-Weighted Average
turns on the computation of the mass-averaged quantity on the surface(s).

Standard Deviation
turns on the computation of the standard deviation of a specified field variable on a surface.

Sum
turns on the computation of the summed quantity on the surface(s).

Uniformity Index - Mass Weighted
turns on the computation of the mass-weighted uniformity index of a quantity on the surface(s).

Uniformity Index - Area Weighted
turns on the computation of the area-weighted uniformity index of a quantity on the surface(s).

Vertex Average
turns on the computation of the vertex-averaged quantity on the surface(s).

Vertex Minimum
turns on the computation of the vertex minimum of a quantity on the surface(s).

Vertex Maximum
turns on the computation of the vertex maximum of a quantity on the surface(s).

Volume Flow Rate
turns on the computation of the volume flow rate through the surface(s).

Custom Vectors
allows you to define custom vectors if you selected **Custom Vector Based Flux**, **Custom Vector Flux**, or **Custom Vector Weighted Average** from the **Report Type** drop-down list.

Field Variable
contains a list of the field variables that can be used in the surface integrations. This option is not active if the **Area**, **Mass Flow Rate**, or **Volume Flow Rate** option is active.

Surfaces
is a selectable list of surfaces.

Area
displays the result of the area summation over all the selected surfaces. This label is visible when **Area** is active.

Area-Weighted Average
displays the result of the area-weighted average computation over all the selected surfaces. This label is visible when **Area-Weighted Average** is active.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Average of Facet Values
displays the result of the facet-averaged computation over all the selected surfaces. This label is visible when **Facet Average** is active.

Minimum of Facet Values
displays the minimum facet value on all the selected surfaces. This label is visible when **Facet Minimum** is active.

Maximum of Facet Values
displays the maximum facet value on all the selected surfaces. This label is visible when **Facet Maximum** is active.

Flow Rate
displays the result of the flow rate computation over all the selected surfaces. This label is visible when **Flow Rate** is active.

Integral
displays the result of the integral computation over all the selected surfaces. This label is visible when **Integral** is active.

Mass Flow Rate
displays the result of the mass flow rate computation over all the selected surfaces. This label is visible when **Mass Flow Rate** is active.

Mass-Weighted Average
displays the result of the mass-averaged computation over all the selected surfaces. This label is visible when **Mass-Weighted Average** is active.

Standard Deviation
displays the result of the standard deviation computation over all the selected surfaces. This label is visible when **Standard Deviation** is active.

Sum of Facet Values
displays the result of the summation over all the selected surfaces. This label is visible when **Sum** is active.

Uniformity Index Mass-Wt.
displays the mass-weighted uniformity index value on all the selected surfaces. This label is visible when **Uniformity Index - Mass Weighted** is active.

Uniformity Index Area-Wt.
displays the area-weighted uniformity index value on all the selected surfaces. This label is visible when **Uniformity Index - Area Weighted** is active.

Average of Surface Vertex Values
displays the result of the vertex-averaged computation over all the selected surfaces. This label is visible when **Vertex Average** is active.

Minimum of Vertex Values
displays the minimum facet value on all the selected surfaces. This label is visible when **Vertex Minimum** is active.

Maximum of Vertex Values
displays the maximum facet value on all the selected surfaces. This label is visible when **Vertex Maximum** is active.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Volumetric Flow Rate
displays the result of the volumetric flow rate computation over all the selected surfaces. This label is visible when **Volume Flow Rate** is active.

Highlight Surfaces
when enabled highlights the surfaces (selected in the **Surface Integrals** dialog box) in the graphics window.

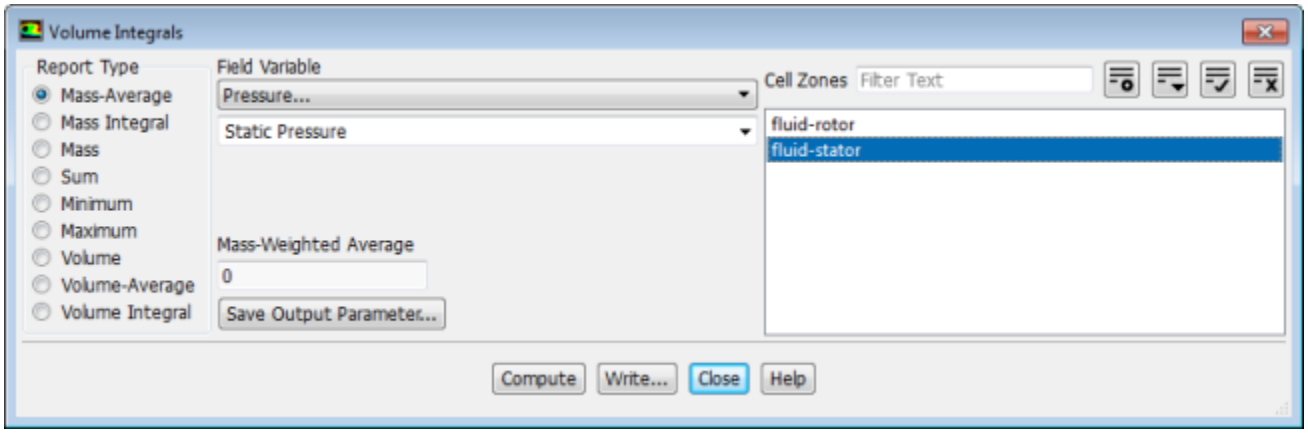
Save Output Parameter...
opens the Save Output Parameter Dialog Box (p. 2631).

Compute
computes the specified integration on the selected surfaces.

Write...
opens The Select File Dialog Box (p. 19), which you can use to save the reported values to a file.

37.21.5. Volume Integrals Dialog Box

The **Volume Integrals** dialog box allows you to compute the volume, sum, maximum, minimum, volume integral, volume-averaged quantity, mass integral, or mass-averaged quantity of a specified field variable on a selected list of cell zones. See Volume Integration (p. 1922) for details.



Controls

Report Type
contains option buttons that control the method of volume integration.

Mass-Average
turns on the computation of the mass-averaged quantity on the cell zone.

Mass Integral
turns on the computation of the mass integral on the cell zone.

Mass
turns on the computation of the total mass in the cell zone for the selected phase.

Sum
turns on the computation of the summation over all cells in the selected zone.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sum*2Pi
computes the summation over all cells in the selected zone of a 2D axisymmetric model and multiplies the result by 2π to give the summation over the revolved domain. This option is only available in 2D axisymmetric cases.

Minimum
computes the minimum value of the selected variable at each cell in the selected zone.

Maximum
computes the maximum value of the selected variable at each cell in the selected zone.

Volume
turns on the computation of the cell zone volume.

Volume Integral
turns on the computation of the volume integral on the cell zone.

Volume-Average
turns on the computation of the volume-weighted average on the cell zone.

Field Variable
contains a list of the field variables that can be used in the sum, volume integral, and average computations. This option is not active if the **Volume** option is active.

Cell Zones
is a selectable list of cell zones.

Total Volume
displays the result of the volume computation over all the selected zones. This label is visible when **Volume** is active.

Sum
displays the result of the summation over all the selected zones. This label is visible when **Sum** is active.

Sum *2Pi
displays the result of the summation over all the selected zones multiplied by 2π. This label is visible when **Sum*2Pi** is active.

Max
displays the result of the maximum value of the selected zone(s). This label is visible when **Maximum** is active.

Min
displays the result of the minimum value of the selected zone(s). This label is visible when **Minimum** is active.

Total Volume Integral
displays the result of the volume-integral computation over all the selected zones. This label is visible when **Volume Integral** is active.

Volume-Weighted Average
displays the result of the volume-averaged computation over all the selected zones. This label is visible when **Volume-Average** is active.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Total Mass-Weighted Integral
displays the result of the mass-integral computation over all the selected zones. This label is visible when **Mass Integral** is active.

Mass-Weighted Average
displays the result of the mass-averaged computation over all the selected zones. This label is visible when **Mass-Average** is active.

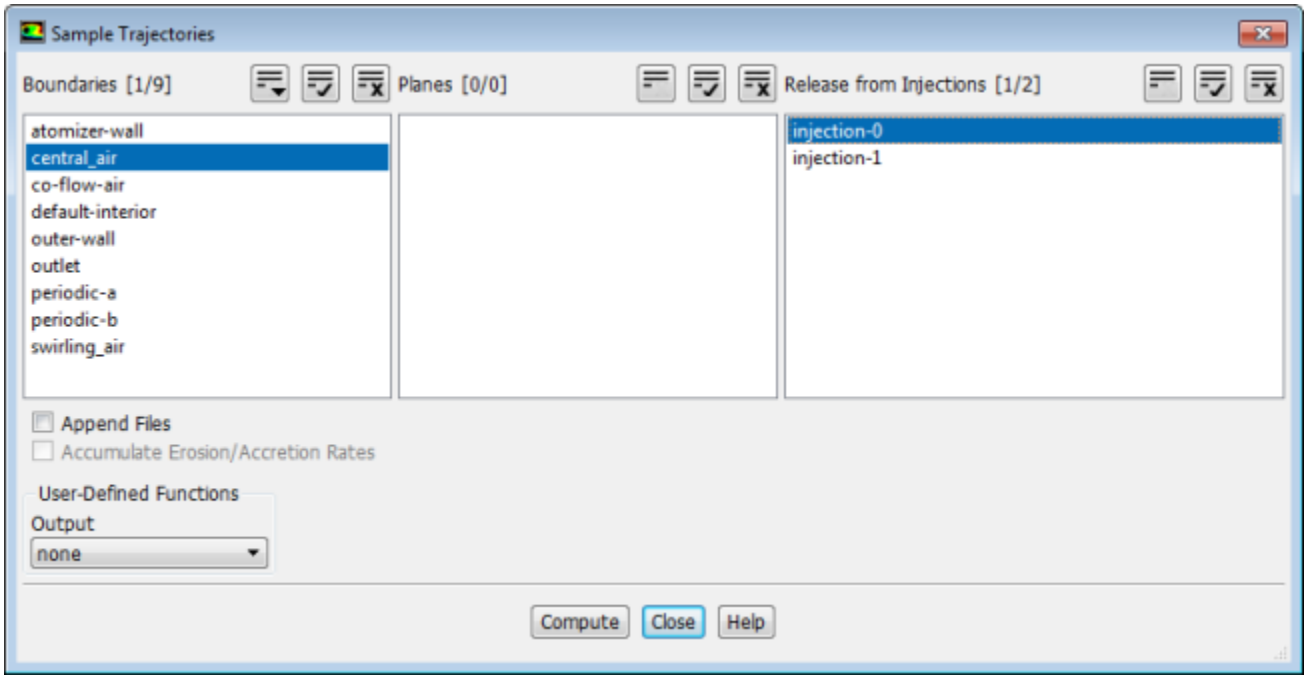
Save Output Parameter...
opens the Save Output Parameter Dialog Box (p. 2631).

Compute
computes the specified integration on the selected zones.

Write...
opens The Select File Dialog Box (p. 19), which you can use to save the reported values to a file.

37.21.6. Sample Trajectories Dialog Box

The **Sample Trajectories** dialog box allows the writing of particle states (position, velocity, diameter, temperature, and mass flow rate) at various boundaries and planes (lines in 2D). See Sampling of Trajectories (p. 1355) for details about the items below.



Controls

Boundaries
lists boundaries that can be chosen as the surfaces at which samples will be written.

Lines
(in 2D) lists lines that can be chosen as the surfaces at which samples will be written.

Planes
(in 3D) lists planes that can be chosen as the surfaces at which samples will be written.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Release From Injections
lists injections from which the injection to be tracked is chosen.

Append Files
causes the results of multiple calculations to be appended to a single file.

Accumulate Erosion/Accretion Rates
causes erosion and accretion rates to be accumulated for repeated trajectory calculations.

User-Defined Functions
allow control of the format and the information written for the sample output.

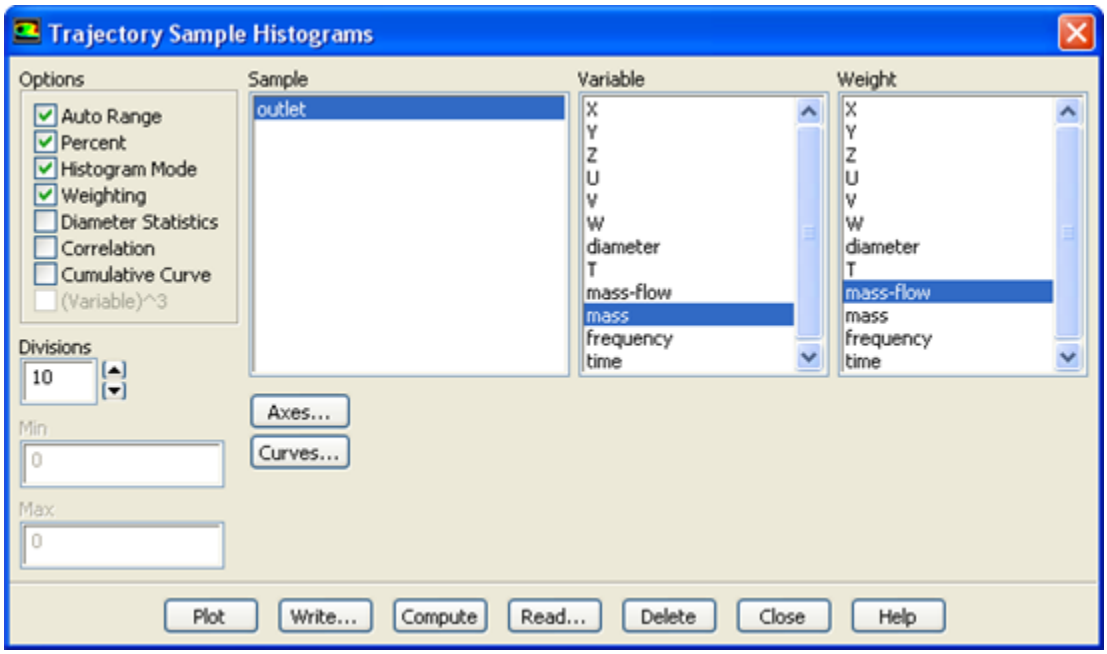
Output
contains a drop-down list of available user-defined functions.

Compute
causes the particles to be tracked and their status to be written to files when they encounter selected surfaces. This button will not appear for unsteady particle tracking.

Start
initiates sampling for unsteady particle tracking. This button will replace the **Compute** button if you are performing unsteady particle tracking. After you click it, it will change to the **Stop** button. Click **Stop** to stop the sampling. (The label will change back to **Start**.)

37.21.7. Trajectory Sample Histograms Dialog Box

The **Trajectory Sample Histograms** dialog box allows the plotting of histograms from sample files created in the Sample Trajectories Dialog Box (p. 2622). See Histogram Reporting of Samples (p. 1356) for details about the items below.



Controls

Options
contains check buttons for histogram options.

Auto Range
toggles between automatic and manual settings of the histogram range.

Percent
causes the plot to indicate the percent of particles. Deselecting this will result in the actual number of particles being plotted.

Histogram Mode
allows you to display the histogram with or without bars.

Weighting
allows you to apply a weight to the data sample.

Diameter Statistics
allows you to display a summary of diameter statistics for a selected variable in the console window.

Correlation
allows you to choose correlations between how one particle variable depends on another particle variable.

Cumulative Curve
allows you to compute a cumulative distribution curve for a selected variable.

(Variable^3)
allows you to plot the cumulative mass distribution for a constant particle density using the particle diameter.

Divisions
sets the number of "bins" in the histogram.

Sample
lists the data samples that have been read in.

Variable
lists the fields variables available in the selected sample.

Weight
lists the weighted fields variables available in the selected sample.

Correlation
lists the sampled variables, allowing you to choose the correlation variable.

Min
displays the minimum value of the variable selected in the **Variable** list. If **Auto Range** is off, you can set the minimum by typing a new value.

Max
displays the maximum value of the variable selected in the **Fields** list. If **Auto Range** is off, you can set the maximum by typing a new value.

Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the histogram axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the histogram.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plot
displays the histogram in the active graphics window.

Write...
stores the histograms in an XY-plot file format

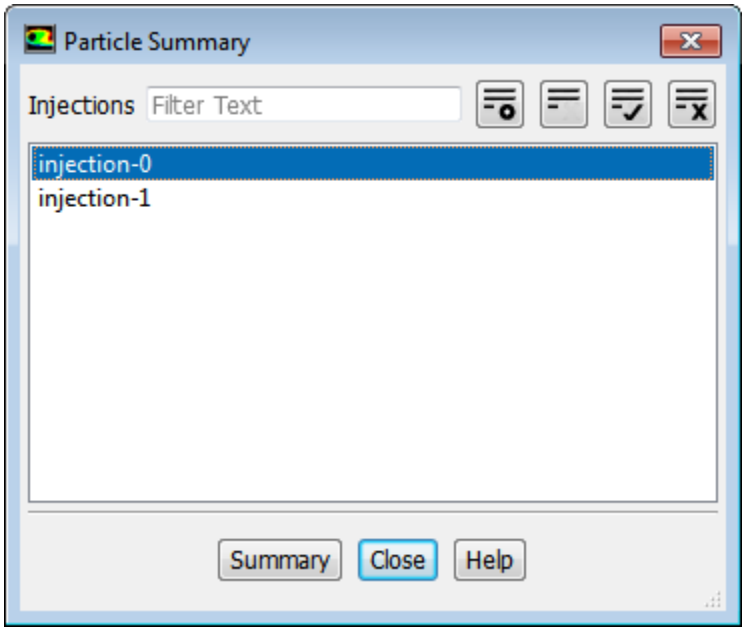
Compute
updates the **Min** and **Max** values.

Read...
opens The Select File Dialog Box (p. 19), where you can select a sample file to be read.

Delete
removes the sample selected in the **Sample** list.

37.21.8. Particle Summary Dialog Box

The **Particle Summary** dialog box allows you to report a summary for particle injections. See Summary Reporting of Current Particles (p. 1358) for details about the items below.



Controls

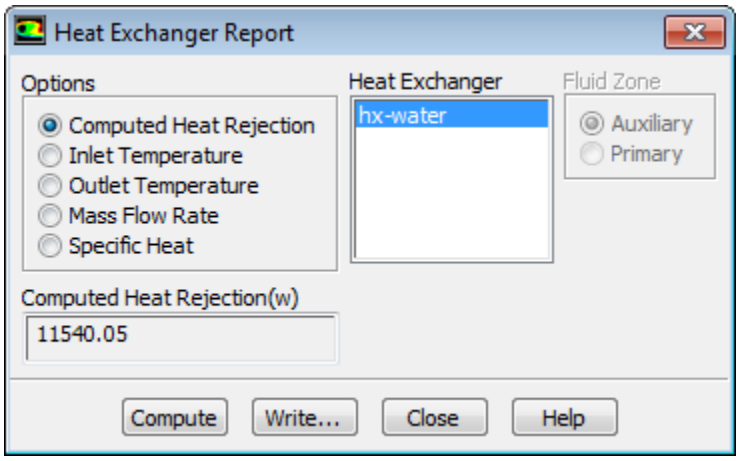
Injections
lists the particle injection(s) for which you can generate a summary.

Summary
prints the injection summary in the console window.

37.21.9. Heat Exchanger Report Dialog Box

The **Heat Exchanger Report** dialog box allows you to report a summary for heat exchangers. See Postprocessing for the Heat Exchanger Model (p. 950) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
lists the available reporting options for the heat exchanger.

Computed Heat Rejection
allows you to report the heat rejection calculated from the heat exchanger.

Inlet Temperature
allows you to report the inlet temperature for both the primary and the auxiliary heat exchanger fluid.

Outlet Temperature
allows you to report the outlet temperature for both the primary and the auxiliary heat exchanger fluid.

Mass Flow Rate
allows you to report the mass flow rate for both the primary and the auxiliary heat exchanger fluid.

Specific Heat
allows you to report the specific heat for both the primary and the auxiliary heat exchanger fluid.

Result
displays the results of the calculations once the **Compute** button is selected.

Heat Exchanger
displays a list of heat exchanger fluid zones

Fluid Zone
(not available when **Computed Heat Rejection** option is selected.) allows you to report quantities for either the primary or auxiliary fluid zones.

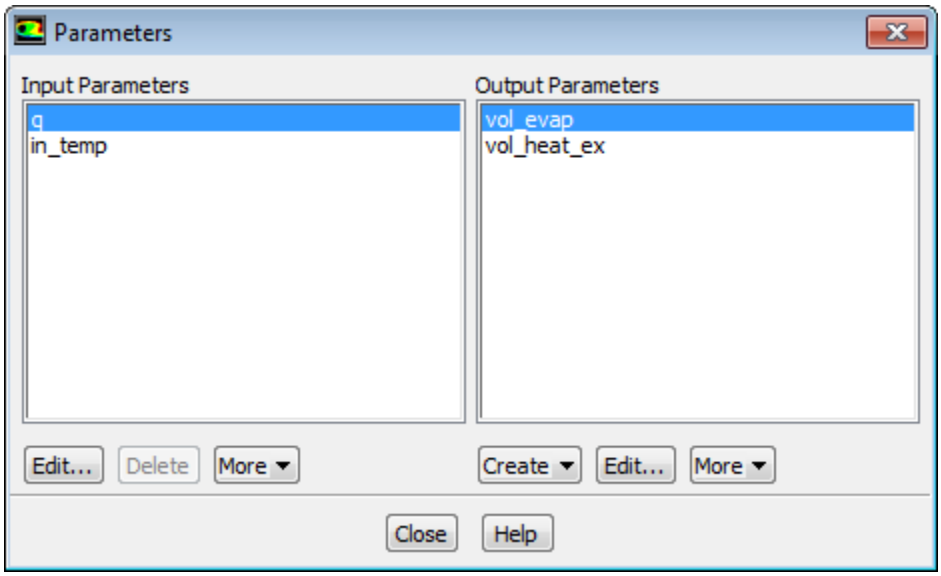
Compute
computes the specified quantity on the selected zones.

Write...
opens The Select File Dialog Box (p. 19), which you can use to save the reported values to a file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.21.10. Parameters Dialog Box

The **Parameters** dialog box allows you to create input parameters (in Scheme or user-defined function procedures only) and output parameters, which allow you to compare reporting values for different cases, or include reporting values in the function minimized by the mesh morpher/optimizer. See Creating Output Parameters (p. 1909) for details about the items below.



Controls

Input Parameters
contains a list of existing input parameters. See Defining and Viewing Parameters (p. 243) for details about creating input parameters.

Edit...
opens the Input Parameter Properties Dialog Box (p. 2631).

> **Important**
>
> When using ANSYS Fluent in ANSYS Workbench, parameters are not editable, so the **Edit...** button becomes the **View...** button. This opens the Input Parameter Properties Dialog Box (p. 2631) where the parameter properties can only be viewed. For more information, see the separate ANSYS Fluent in **Workbench** User's Guide.

Delete
removes the selected input parameter from the list of **Input Parameters**.

More

contains a drop-down list that allows more advanced use of input parameters. Available options include:

Use in Scheme Procedure
opens the Use Input Parameter in Scheme Procedure Dialog Box (p. 2628).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use in UDF
opens the Use Input Parameter for UDF Dialog Box (p. 2629).

Output Parameters
contains a list of existing output parameters.

Create
opens the Report Definitions Dialog Box (p. 2785), allowing you to create additional output parameters based on report definitions.

Edit...
opens the dialog box corresponding to the selected item in the **Output Parameters** list.

More
contains a drop-down list containing additional tasks that you can perform, including:

Delete
removes the selected output parameter from the list of **Output Parameters**.

Print to Console
reports values to the console window. If you select multiple output parameters, then the output includes values from multiple output parameters.

Print All to Console
outputs the values from all output parameters to the console window.

Write...
allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

Write All...
prompts you for a file name and then writes the values for all of the output parameters to a file.

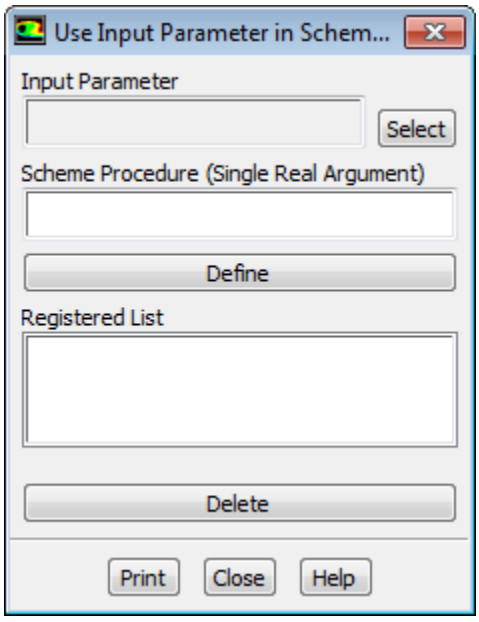
Note

ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, `parameter-1`, `parameter-2`, `parameter-3`, and so on) If a parameter is deleted, the default name is not reused. For example, if you have `parameter-1`, `parameter-2`, and `parameter-3`, then delete `parameter-2` and create a new parameter, the default name for the new parameter will be `parameter-4`.

37.21.11. Use Input Parameter in Scheme Procedure Dialog Box

The **Use Input Parameter in Scheme Procedure** dialog box allows you to use the input parameter in a Scheme procedure. In turn, this Scheme procedure can also use text user interface (TUI) commands. For more information, see Working With Advanced Parameter Options (p. 247).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Input Parameter
contains the name of an input parameter.

Select
opens the Select Input Parameter Dialog Box (p. 2384) where an input parameter can be chosen.

Scheme Procedure (Single Real Argument)
contains a procedure name (if already defined using a Scheme file) or procedure body written in the Scheme language using `lambda`. This procedure should receive one real argument.

Define
registers the selected input parameter.

Registered List
contains a list of registered input parameters.

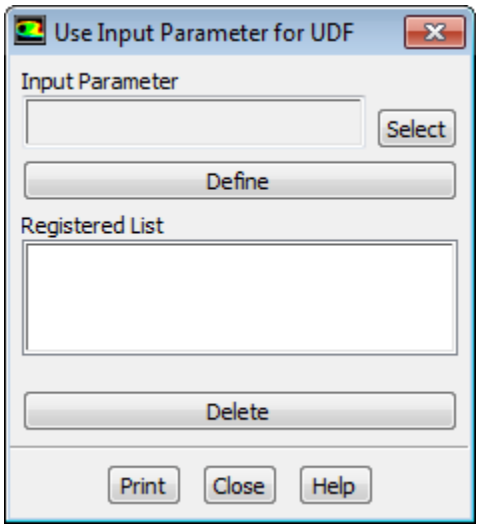
Delete
removes a selected registered input parameter from the list.

Print
prints details of the registered input parameters.

37.21.12. Use Input Parameter for UDF Dialog Box

The **Use Input Parameter for UDF** dialog box allows you to select the input parameters that can be used inside a user-defined function (UDF) during calculations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Input Parameter
contains the name of an input parameter.

Select
opens the Select Input Parameter Dialog Box (p. 2384) where an input parameter can be chosen.

Define
registers the selected input parameter.

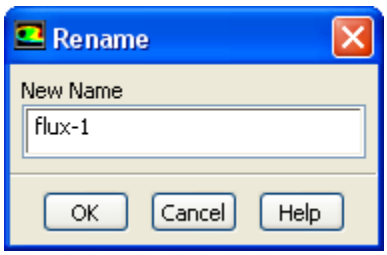
Registered List
contains a list of registered input parameters.

Delete
removes a selected registered input parameter from the list.

Print
prints the ID of the registered input parameters. The ID values are used to access the value of the parameter in the user-defined function.

37.21.13. Rename Dialog Box

The **Rename** dialog box allows you to change the name of the output parameter that you created.



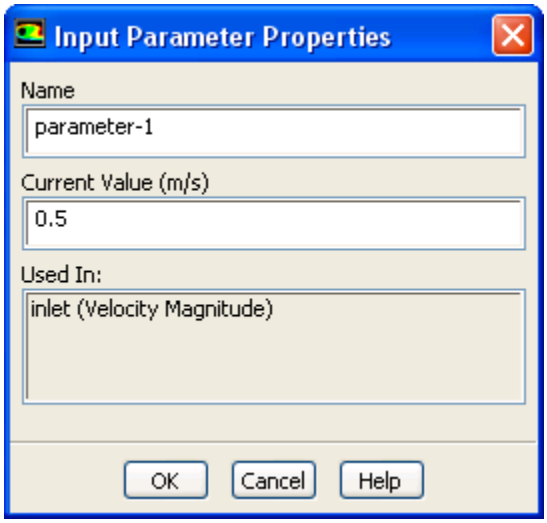
Controls

New Name
contains the new name of the output parameter.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

37.21.14. Input Parameter Properties Dialog Box

The **Input Parameter Properties** dialog box allows you to create input parameters, which allow you to compare reporting values for different cases. See Creating Output Parameters (p. 1909) for details about the items below.



Controls

Name
contains the name of the input parameter.

Current Value
contains the current value of the input parameter.

Used In
indicates the cell zone or boundary condition where the input parameter is currently used.

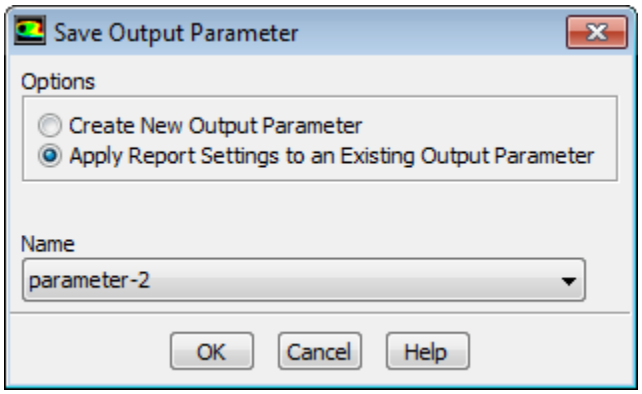
Note

ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, `parameter-1`, `parameter-2`, `parameter-3`, and so on) If a parameter is deleted, the default name is not reused. For example, if you have `parameter-1`, `parameter-2`, and `parameter-3`, then delete `parameter-2` and create a new parameter, the default name for the new parameter will be `parameter-4`.

37.21.15. Save Output Parameter Dialog Box

The **Save Output Parameter** dialog box allows you to save specific output parameters that allow you to compare reporting values for different cases. See Creating Output Parameters (p. 1909) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains options for saving your output parameters.

Create New Output Parameter
allows you to create a new output parameter.

Apply Report Settings to an Existing Output Parameter
allows you to overwrite an existing output parameter of the same type.

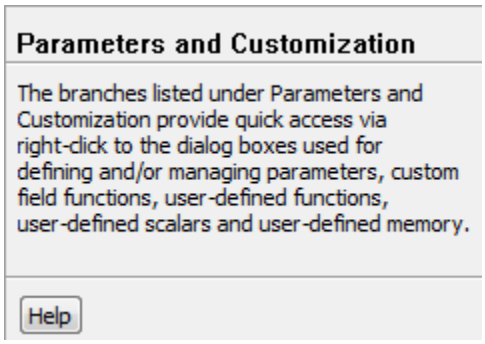
Name
contains the name for the current output parameter.

Note

ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, `parameter-1`, `parameter-2`, `parameter-3`, and so on) If a parameter is deleted, the default name is not reused. For example, if you have `parameter-1`, `parameter-2`, and `parameter-3`, then delete `parameter-2` and create a new parameter, the default name for the new parameter will be `parameter-4`.

37.22. Parameters and Customization Task Page

The **Parameters and Customization** task page introduces you to the parameterization and customization tools available for use in solving your CFD simulation using ANSYS Fluent.



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 38: Ribbon Reference Guide

This reference guide provides information about the ribbon in ANSYS Fluent.

38.1. File Ribbon Tab
38.2. Dialog Boxes Available from the Ribbon

38.1. File Ribbon Tab

For additional information, see the following sections:

38.1.1. File/Read/Mesh...

38.1.65. File/Save Picture...
38.1.66. File/Data File Quantities...
38.1.67. File/Batch Options...
38.1.68. File/Exit

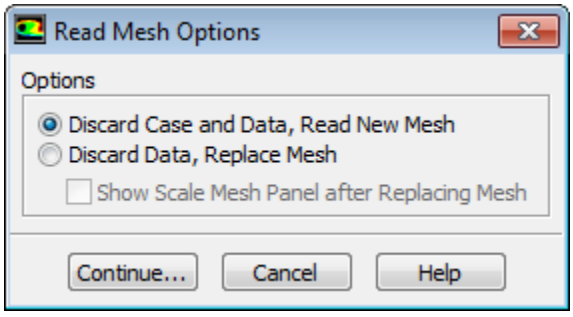
38.1.1. File/Read/Mesh...

The **File/Read/Mesh...** ribbon tab item opens the Read Mesh Options Dialog Box (p. 2634), which allows you to read or replace a mesh.

38.1.1.1. Read Mesh Options Dialog Box

The **Read Mesh Options** dialog box is used to read or replace a mesh. See Reading Mesh Files (p. 44) for more information.

File → Read → Mesh...



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Options

allows you to read in a new mesh or replace the existing mesh.

Discard Case And Data, Read New Mesh

results in both the case and data files being discarded when reading in a new mesh.

Discard Data, Replace Mesh

results in the data file being discarded when replacing an existing mesh.

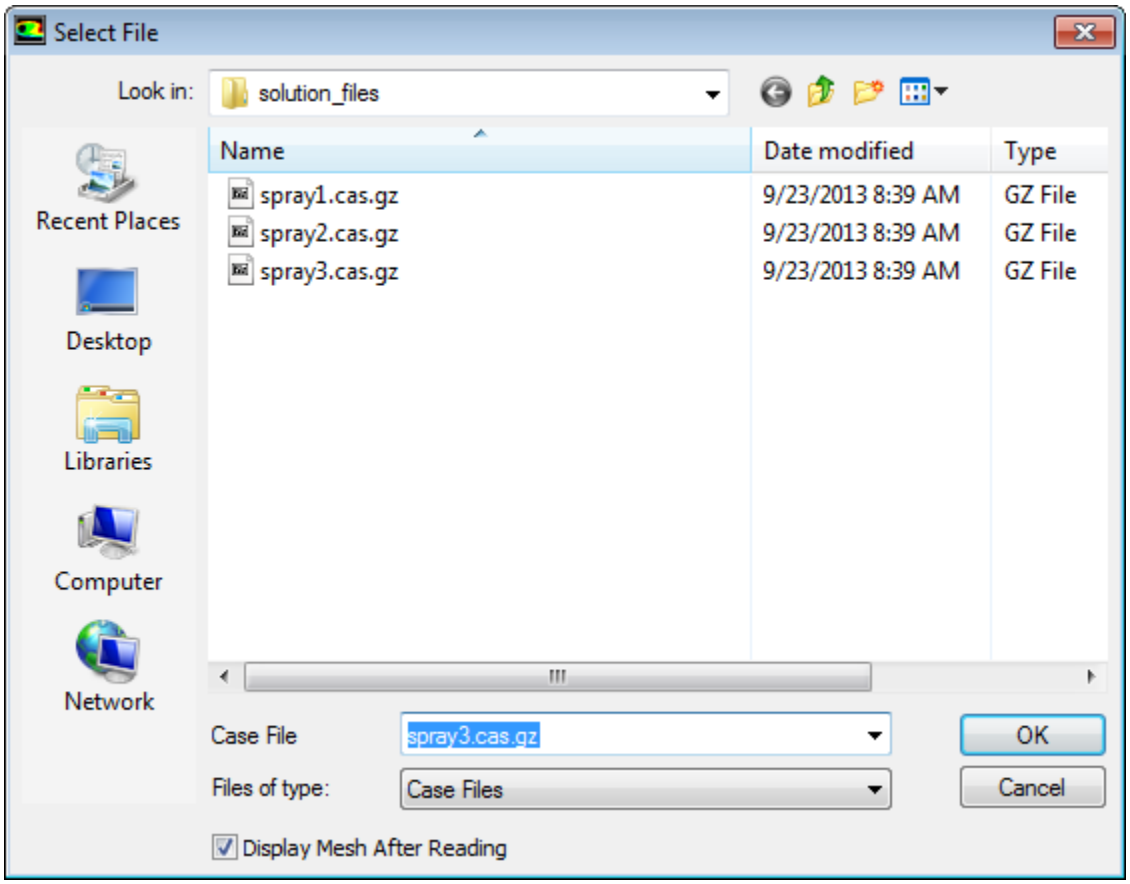
Show Scale Mesh Panel After Replacing Mesh

gives you the option to have the Scale Mesh Dialog Box (p. 2162) appear automatically for you to check or scale your mesh.

38.1.2. File/Read/Case...

The **File/Read/Case...** ribbon tab item is used to read in an ANSYS Fluent case file (extension `.cas`), or a mesh file (extension `.msh`, `.grd`, `.MSH`, or `.GRD`) that has been saved in the native format for ANSYS Fluent. See Reading Mesh Files (p. 44) and Reading and Writing Case and Data Files (p. 45) for details.

The **File/Read/Case...** ribbon tab item opens The Select File Dialog Box (p. 19), which allows you to select the appropriate file to be read.



38.1.3. File/Read/Data...

The **File/Read/Data...** ribbon tab item is used to read in an ANSYS Fluent data file (which has a `.dat` extension) or parallel data file (which has a `.pdat` extension). This item will not be available until you read in a case or mesh file. See Reading and Writing Data Files (p. 47) and Reading and Writing Parallel Data Files (p. 51) for details.

The **File/Read/Data...** ribbon tab item opens The Select File Dialog Box (p. 19), which allows you to select the appropriate file to be read.

38.1.4. File/Read/Case & Data...

The **File/Read/Case & Data...** ribbon tab item is used to read in an ANSYS Fluent case file and the corresponding data file (for example, `myfile.cas` and `myfile.dat`) together. See Reading and Writing Case and Data Files Together (p. 47) for details.

The **File/Read/Case & Data...** ribbon tab item opens The Select File Dialog Box (p. 19), which allows you to select the appropriate files to be read. Select the appropriate case file, and the corresponding data file (that is, the file having the same name with a `.dat` extension) will also be read in.

38.1.5. File/Read/PDF...

The **File/Read/PDF...** ribbon tab item is used to read a PDF file (extension `.pdf`) created by ANSYS Fluent for use with the non-premixed or partially premixed combustion model. This item is available only when the non-premixed or partially premixed combustion model has been enabled. See Saving the Look-Up Tables (p. 1068) for details.

38.1.6. File/Read/ISAT Table...

The **File/Read/ISAT Table...** ribbon tab item is used to read an ISAT table (extension `.isat`) for use with the Composition PDF Transport model. This item is available only when the Composition PDF Transport model has been enabled. See Using ISAT Efficiently (p. 1130) for details.

38.1.7. File/Read/DTRM Rays...

The **File/Read/DTRM Rays...** ribbon tab item is used to read a ray file (extension `.ray`) created by ANSYS Fluent for use with the DTRM (radiation model). This item is available only when the DTRM has been enabled. See Writing and Reading the DTRM Ray File (p. 850) for details.

38.1.8. File/Read/View Factors...

The **File/Read/View Factors...** ribbon tab item is used to read in a view factor file for use with the surface-to-surface (S2S) radiation model. This item is available only when the S2S model has been enabled. See Reading View Factors into ANSYS Fluent (p. 863) for details.

38.1.9. File/Read/Profile...

The **File/Read/Profile...** ribbon tab item opens the **Select File** dialog box for reading profiles (Reading Profile Files (p. 54)), It is used to read a cell zone or boundary condition profile file (extension `.prof`). A profile file defines profiles that can be used to specify flow conditions for a cell zone or a boundary. See Profiles (p. 435) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.1.10. File/Read/Scheme...

The **File/Read/Scheme...** ribbon tab item is used to read in a Scheme source file (extension `.scm`). See Reading Scheme Source Files (p. 57) for details.

38.1.11. File/Read/Journal...

The **File/Read/Journal...** ribbon tab item is used to read in a journal file (extension `.jou`) containing a sequence of ANSYS Fluent commands. You can create a journal file using the **File/Write/Journal...** ribbon tab item. See Creating and Reading Journal Files (p. 57) for details.

38.1.12. File/Write/Case...

The **File/Write/Case...** ribbon tab item is used to save an ANSYS Fluent case file. See Reading and Writing Case Files (p. 46) for details.

The **File/Write/Case...** ribbon tab item opens The Select File Dialog Box (p. 19), which allows you to save the file with a name of choice. The dialog box is similar to the **Select File** dialog box for reading files, except that it has an additional option for writing binary files.

Important

- When ANSYS Fluent writes a case file, the `.cas` extension is added to the file name specified, unless the name already ends with `.cas`.
- You can also write a compressed file by appending `.gz` or `.Z` to the file name. (See Reading and Writing Compressed Files (p. 41) for details about file compression.)

38.1.13. File/Write/Data...

The **File/Write/Data...** ribbon tab item is used to save an ANSYS Fluent data file (which has a `.dat` extension) or parallel data file (which has a `.pdat` extension). See Reading and Writing Data Files (p. 47) and Reading and Writing Parallel Data Files (p. 51) for details.

Important

- When ANSYS Fluent writes a data file, the `.dat` extension is added to the file name specified, unless the name already ends with `.dat` or `.pdat`.
- You can compress data files by appending `.gz` or `.Z` to the file name (see Reading and Writing Compressed Files (p. 41) for details about file compression). To compress parallel data files (that is, files saved with a `.pdat` extension), you must use asynchronous file compression (see Reading and Writing Case and Data Files (p. 45)).

38.1.14. File/Write/Case & Data...

The **File/Write/Case & Data...** ribbon tab item is used to save an ANSYS Fluent case file and data file at the same time (for example, `myfile.cas` and `myfile.dat`). See Reading and Writing Case and Data Files Together (p. 47) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enter the name of the case file in the text entry box in the **Select File** dialog box and the corresponding data file (same file name, but with a `.dat` extension) will also be written.

38.1.15. File/Write/PDF...

The **File/Write/PDF...** ribbon tab item is used to write a PDF file after computing the look-up tables using the non-premixed or partially premixed combustion model in ANSYS Fluent. This item is available only when the non-premixed or partially premixed combustion model has been enabled. See Saving the Look-Up Tables (p. 1068) for details.

38.1.16. File/Write/ISAT Table...

The **File/Write/ISAT Table...** ribbon tab item is used to write an ISAT table. See Using ISAT Efficiently (p. 1130) for details.

38.1.17. File/Write/Flamelet...

The **File/Write/Flamelet...** ribbon tab item is used to write a flamelet file generated using the non-premixed or partially premixed combustion model in ANSYS Fluent. This item is available only when the non-premixed or partially premixed combustion model has been enabled. See The Diffusion Flamelet Models Theory in the Theory Guide for details.

38.1.18. File/Write/Surface Clusters...

The **File/Write/Surface Clusters...** ribbon tab item is used to set parameters related to surface clusters and view factors for the surface-to-surface radiation model. It opens the View Factors and Clustering Dialog Box (p. 2194). The dialog box that you open using the **File/Write/Surface Clusters...** ribbon tab item is different than the one opened via the **Settings...** button in the **Radiation Model** dialog box, in that it saves the settings you specify to a file that can be used to calculate the view factors outside of ANSYS Fluent (see Computing View Factors Outside ANSYS Fluent (p. 862)). When you click **OK**, The Select File Dialog Box (p. 19) will open so that you can specify a name for the file where ANSYS Fluent should save the settings.

38.1.19. File/Write/Profile...

The **File/Write/Profile...** ribbon tab item opens the Write Profile Dialog Box (p. 2388).

38.1.20. File/Write/Autosave...

The **File/Write/Autosave...** ribbon tab item opens the Autosave Dialog Box (p. 2527).

38.1.21. File/Write/Boundary Mesh...

The **File/Write/Boundary Mesh...** ribbon tab item is used to write the boundary zones (surface mesh) of the domain to a file. You can then read this file into the meshing mode of Fluent or GAMBIT to produce an improved volume mesh. See Writing a Boundary Mesh (p. 56) for details.

38.1.22. File/Write/Start Journal...

The **File/Write/Start Journal...** ribbon tab item is used to start the recording of subsequent ANSYS Fluent commands to a journal file. You can read this journal file back into Fluent later (using the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File/Read/Journal... ribbon tab item) to automate the execution of the recorded commands. See Creating and Reading Journal Files (p. 57) for details.

38.1.23. File/Write/Stop Journal

The **File/Write/Stop Journal** ribbon tab item replaces the **File/Write/Start Journal...** ribbon tab item after the recording of a journal file has begun. The **File/Write/Stop Journal** ribbon tab item is used to end the journal recording. See Creating and Reading Journal Files (p. 57) for details.

38.1.24. File/Write/Start Transcript...

The **File/Write/Start Transcript...** ribbon tab item is used to start the recording of a transcript file containing all input to and output from Fluent. (You cannot read a transcript file back into Fluent.) See Creating Transcript Files (p. 59) for details.

38.1.25. File/Write/Stop Transcript

The **File/Write/Stop Transcript** ribbon tab item replaces the **File/Write/Start Transcript...** ribbon tab item after the recording of a transcript file has begun. The **File/Write/Stop Transcript** ribbon tab item is used to end the transcript recording. See Creating Transcript Files (p. 59) for details.

38.1.26. File/Import/ABAQUS/Input File...

The **File/Import/ABAQUS/Input File...** ribbon tab item is used to import an ABAQUS input file (extension `.inp`), which contains the input description of a finite element model for the ABAQUS finite element program. See ABAQUS Files (p. 62) for details.

38.1.27. File/Import/ABAQUS/Filbin File...

The **File/Import/ABAQUS/Filbin File...** ribbon tab item is used to import an ABAQUS filbin file (extension `.fil`), which contains the finite element model and results data. See ABAQUS Files (p. 62) for details.

38.1.28. File/Import/ABAQUS/ODB File...

The **File/Import/ABAQUS/ODB File...** ribbon tab item is used to import an ABAQUS ODB file with a `.odb` extension. See ABAQUS Files (p. 62) for details.

38.1.29. File/Import/CFX/Definition File...

The **File/Import/CFX/Definition File...** ribbon tab item is used to import a CFX definition file (extension `.def`), which contains mesh information to be read into Fluent. See CFX Files (p. 62) for details.

38.1.30. File/Import/CFX/Result File...

The **File/Import/CFX/Result File...** ribbon tab item is used to import a CFX result file (extension `.res`). See CFX Files (p. 62) for details.

38.1.31. File/Import/CGNS/Mesh...

The **File/Import/CGNS/Mesh...** ribbon tab item is used to read in a CGNS-format mesh file (extension `.cgns`). See Meshes and Data in CGNS Format (p. 63) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.1.32. File/Import/CGNS/Data...

The **File/Import/CGNS/Data...** ribbon tab item is used to read in a CGNS-format data file. See Meshes and Data in CGNS Format (p. 63) for details.

38.1.33. File/Import/CGNS/Mesh & Data...

The **File/Import/CGNS/Mesh & Data...** ribbon tab item is used to read in a set of CGNS-format mesh and data files. See Meshes and Data in CGNS Format (p. 63) for details.

38.1.34. File/Import/EnSight...

The **File/Import/EnSight...** ribbon tab item is used to import EnSight files (extension `.encas` or `.case`). See EnSight Files (p. 64) for details.

38.1.35. File/Import/FIDAP...

The **File/Import/FIDAP...** ribbon tab item is used to import an ANSYS FIDAP neutral file (extension `.FDNEUT` or `.unv`). See ANSYS FIDAP Neutral Files (p. 64) for details.

38.1.36. File/Import/GAMBIT...

The **File/Import/GAMBIT...** ribbon tab item is used to read in a neutral file from GAMBIT. See GAMBIT and GeoMesh Mesh Files (p. 64) for details.

38.1.37. File/Import/HYPERMESH ASCII...

The **File/Import/HYPERMESH ASCII...** ribbon tab item is used to import a **HYPERMESH ASCII** file (extension `.hm`, `.hma`, or `.hmascii`). See HYPERMESH ASCII Files (p. 65) for details.

38.1.38. File/Import/I-deas Universal...

The **File/Import/I-deas Universal...** ribbon tab item is used to import an I-deas Universal file, which contains mesh information and zone types to be read into Fluent. See I-deas Universal Files (p. 65) for details.

38.1.39. File/Import/LSTC/Input File...

The **File/Import/LSTC/Input File...** ribbon tab item is used to import an LSTC input file (extension `.k`, `.key`, or `.dyn`), which contains the input description of a finite element model for the LS-DYNA finite element program. See LSTC Files (p. 65) for details.

38.1.40. File/Import/LSTC/State File...

The **File/Import/LSTC/State File...** ribbon tab item is used to import an LSTC state file (extension `.d3plot`), which contains control data, geometry data, and state data. See LSTC Files (p. 65) for details.

38.1.41. File/Import/Marc POST...

The **File/Import/Marc POST...** ribbon tab item is used to import a Marc POST file generated using the MSC Marc finite element program. See Marc POST Files (p. 65) for details

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.1.42. File/Import/Mechanical APDL/Input File...

The **File/Import/Mechanical APDL/Input File...** ribbon tab item is used to import a Mechanical APDL input file (extensions `.ans`, `neu`, `.cdb`, or `.prep7`), which contains mesh information to be read into Fluent. See Mechanical APDL Files (p. 66) for details.

38.1.43. File/Import/Mechanical APDL/Result File...

The **File/Import/Mechanical APDL/Result File...** ribbon tab item is used to import a Mechanical APDL result file (extension `.rfl`, `.rst`, `.rth`, or `.rmg`). See Mechanical APDL Files (p. 66) for details.

38.1.44. File/Import/NASTRAN/Bulkdata File...

The **File/Import/NASTRAN/Bulkdata File...** ribbon tab item is used to import a NASTRAN Bulkdata file (extension `.nas`, `.dat`, or `.bdf`), which contains mesh information to be read into Fluent. See NASTRAN Files (p. 66) for details.

38.1.45. File/Import/NASTRAN/Op2 File...

The **File/Import/NASTRAN/Op2 File...** ribbon tab item is used to import a NASTRAN Op2 file (extension `.op2`), which is an output binary data file containing data used in the NASTRAN finite element program. See NASTRAN Files (p. 66) for details.

38.1.46. File/Import/PATRAN/Neutral File...

The **File/Import/PATRAN/Neutral File...** ribbon tab item is used to read in a PATRAN Neutral file (extension `.neu`, `.out`, or `.pat`) zoned by named components (that is, with the nodes placed into zones based on group name). The PATRAN neutral file contains mesh information to be read into Fluent. See PATRAN Neutral Files (p. 67) for details.

38.1.47. File/Import/PLOT3D/Grid File...

The **File/Import/PLOT3D/Grid File...** ribbon tab item is used to import a PLOT3D grid file (extension `.g`, `.x`, `.xyz`, or `.grd`). See PLOT3D Files (p. 67) for details.

38.1.48. File/Import/PLOT3D/Result File...

The **File/Import/PLOT3D/Result File...** ribbon tab item s used to import a PLOT3D result file (extension `.g`, `.x`, `.xyz`, or `.grd`). See PLOT3D Files (p. 67) for details.

38.1.49. File/Import/PTC Mechanica Design...

The **File/Import/PTC Mechanica Design...** ribbon tab item is used to import a PTC Mechanica Design file (extension `.neu`), which contains analysis, model, and results data (only in binary form). See PTC Mechanica Design Files (p. 67) for details.

38.1.50. File/Import/Tecplot...

The **File/Import/Tecplot...** ribbon tab item is used to read in a Tecplot binary file. See Tecplot Files (p. 67) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.1.51. File/Import/Fluent 4 Case File...

The **File/Import/Fluent 4 Case File...** ribbon tab item is used to read in a case file created in FLUENT 4. See Fluent 4 Case Files (p. 68) for details.

38.1.52. File/Import/PreBFC File...

The **File/Import/PreBFC File...** ribbon tab item is used to read in a structured (quadrilateral or hexahedral) mesh that was created using PreBFC. See PreBFC Files (p. 68) for details.

38.1.53. File/Import/Partition/Metis...

The **File/Import/Partition/Metis...** ribbon tab item is used to partition a mesh and then read it into the parallel version of ANSYS Fluent. See Using the Partition Filter (p. 2052) for an explanation of the difference between this item and the **File/Import/Partition/Metis Zone...** ribbon tab item.

38.1.54. File/Import/Partition/Metis Zone...

The **File/Import/Partition/Metis Zone...** ribbon tab item is used to partition each cell zone in a mesh individually and then read the mesh into the parallel version of ANSYS Fluent. See Using the Partition Filter (p. 2052) for an explanation of the difference between this item and the **File/Import/Partition/Metis...** ribbon tab item.

38.1.55. File/Import/CHEMKIN Mechanism...

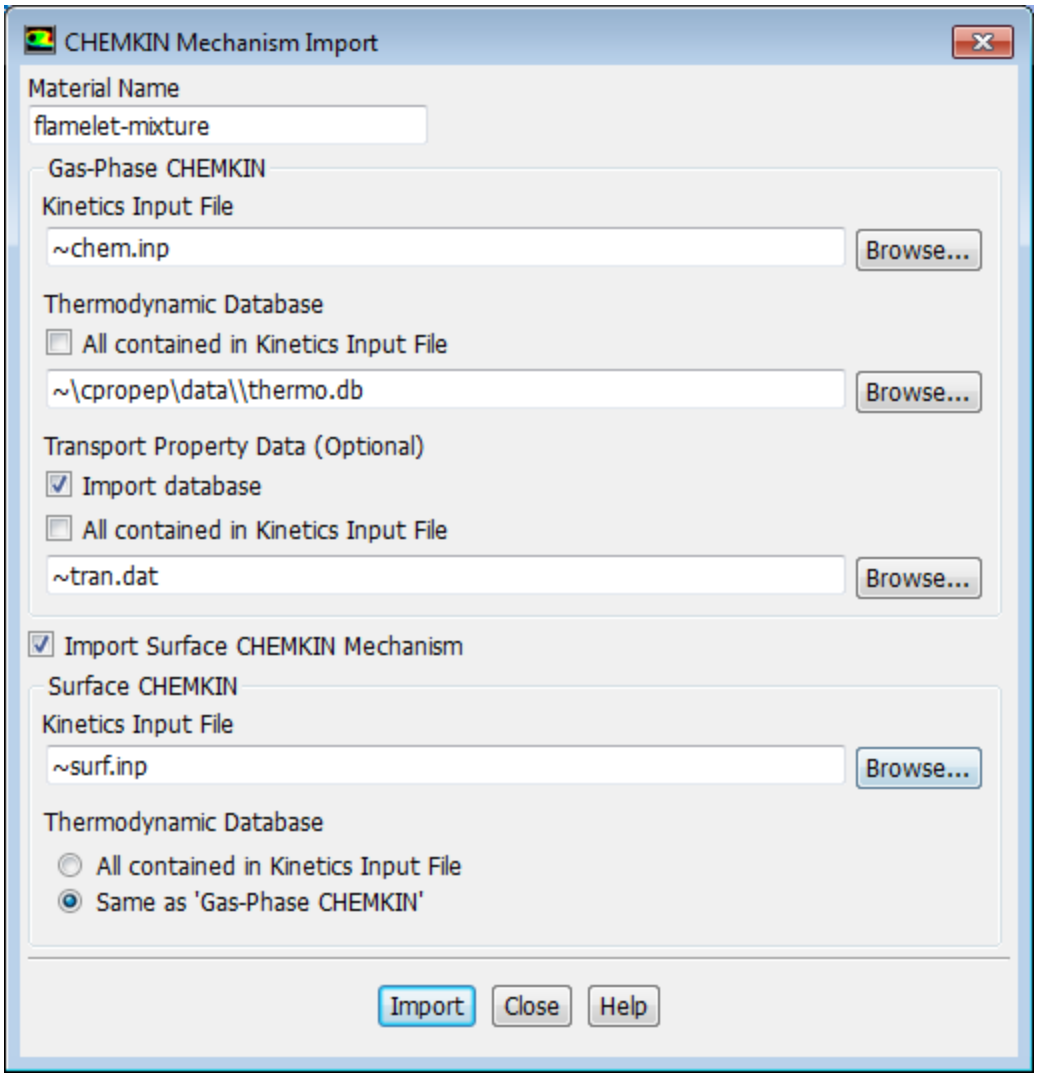
The **File/Import/CHEMKIN Mechanism...** ribbon tab item opens the CHEMKIN Mechanism Import Dialog Box (p. 2642).

38.1.55.1. CHEMKIN Mechanism Import Dialog Box

The **CHEMKIN Mechanism Import** dialog box is used to import a CHEMKIN-format chemical mechanism file into ANSYS Fluent. See Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967) for details. The dialog box can be accessed either from the Species Model Dialog Box (p. 2216) or from the main menu:

File → Import → CHEMKIN Mechanism...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Material Name
specifies a name for the material.

Gas-Phase CHEMKIN
contains inputs for importing the gas-phase CHEMKIN mechanism.

Kinetics Input File
specifies the name of the gas-phase CHEMKIN-format file. If the file is not in the current working folder, include the full path to the folder where it is located.

Thermodynamic Database
specifies thermodynamic property data for species whose thermodynamic data are not specified in the kinetics input file. You can enable **All contained in Kinetics Input Files** to indicate that the kinetics input file contains the thermodynamic data for all the species.

Transport Property Data (Optional)
(if **Import database** is enabled) allows you to specify transport property data for species whose transport data are not specified in the kinetics input file. You can enable **All contained in Kinetics Input Files** to indicate that the kinetics input file contains the transport data for all the species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Import Surface CHEMKIN Mechanism
enables the importing of the surface CHEMKIN mechanism.

Surface CHEMKIN
contains inputs for importing the surface CHEMKIN mechanism. This group box appears only when the **Import Surface CHEMKIN Mechanism** option is enabled.

Kinetics Input File
specifies the name of the surface kinetics CHEMKIN-format file.

Thermodynamic Database
specifies whether the thermodynamic data for the surface-chemistry species will be included in the surface kinetics CHEMKIN-format file (if **All contained in Kinetics Input File** is enabled) or in the thermodynamic database file specified in the **Gas-Phase CHEMKIN** group box (if **Same as 'Gas-Phase CHEMKIN'** is enabled). Note that if no thermodynamic database file is specified in the **Gas-Phase CHEMKIN** group box, the thermodynamic data for all surface-chemistry species must be included the surface kinetics input file.

Import
imports the specified Chemkin reaction mechanism and thermal files and saves the imported data in the Fluent case file. Note that carrying the original input files along with the Fluent case file is not required. ANSYS Fluent will automatically regenerate these files when needed (for example, when using the CHEMKIN-CFD solver).

38.1.56. File/Export/Solution Data...

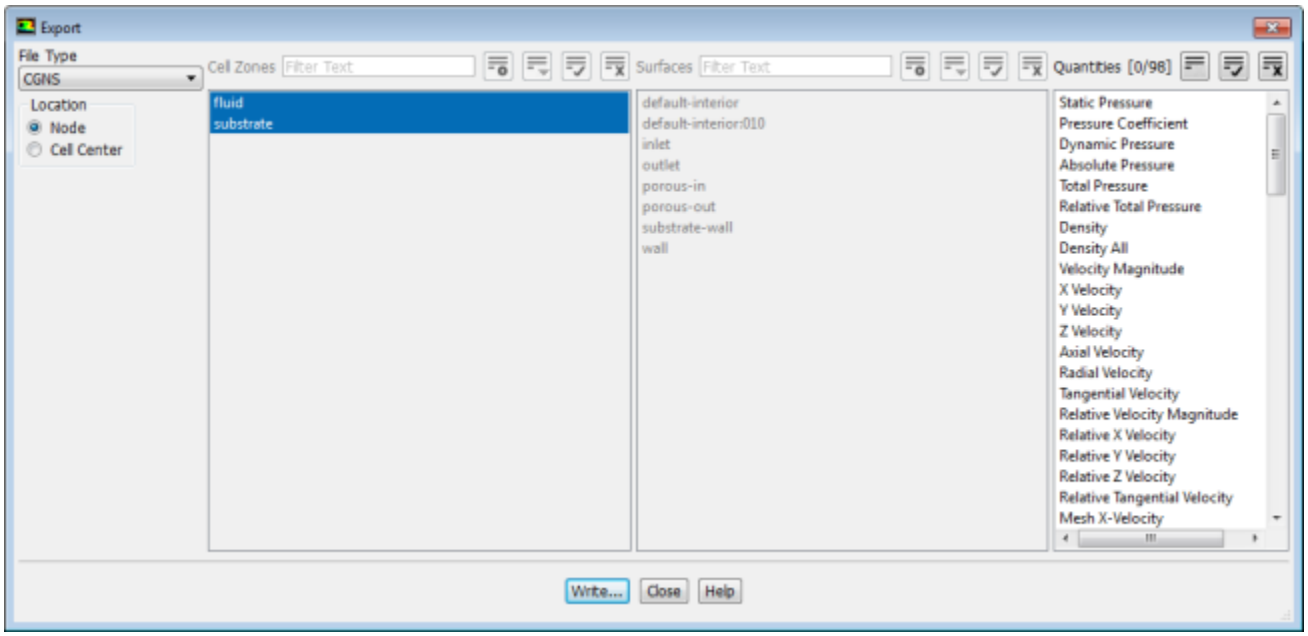
The **File/Export/Solution Data...** ribbon tab item opens the Export Dialog Box (p. 2644).

38.1.56.1. Export Dialog Box

The **Export** dialog box allows you to write data that can be read by other data visualization and post-processing tools. See Exporting Solution Data (p. 69) for a complete description of the available data formats and how to use the dialog box.

File → Export → Solution Data...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

File Type

contains a drop-down list that controls the output file format that will be written using the **Write...** button.

ABAQUS

allows you to specify the surface(s) and optional loads, based on the kind of finite element analysis selected, to be exported to an ABAQUS file (extension `.inp`).

ASCII

allows you to specify the surface(s), scalars, location in the cell from which the values of scalar functions are to be taken, and the delimiter separating the fields, to be exported to an ASCII file.

AVS

allows you to specify the scalars you want to write to be exported to an AVS file.

CFD-Post Compatible

allows you to specify the scalars you want to write, the cell zones from which the values of scalar functions are to be taken, the file format, and whether a case file is written, as part of the exporting of files that are compatible with the CFD-Post application (that is, `.cdat` and `.cst` files).

CGNS

allows you to specify the scalars you want to write and the location from which the values of scalar functions are to be taken, to be exported to a CGNS file (extension `.cgns`).

Data Explorer

allows you to specify the surface(s) and the scalars you want to write to be exported to a Data Explorer file (extension `.dx`).

EnSight Case Gold

allows you to specify the scalars you want to write, the cell zones, interior zone surfaces, and location in the cell from which the values of scalar functions are to be taken, and the file format, to be exported to an EnSight file (extension `.geo`, `.vel`, `.scl1`, or `.encas`).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

FAST
allows you to specify the scalars you want to write, to be exported as a grid file (Plot3D format), a velocity file, and a scalar file. This option is available only for a triangular or tetrahedral mesh.

FAST Solution
allows you to export a single file containing density, velocity, and total energy data. This option is available only for a triangular or tetrahedral mesh.

Fieldview Unstructured
allows you to specify the scalars you want to write and the cell zones or surfaces from which the values of scalar functions are to be taken, to be exported to a FIELDVIEW binary file (extension `.fvuns`) and a regions file (extension `.fvuns.fvreg`).

Note

You must deselect all cell zones before you can select any surfaces.

I-deas Universal
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to an I-deas Universal file.

Mechanical APDL Input
allows you to specify the surface(s) and optional loads, based on the kind of finite element analysis selected, to be exported to a Mechanical APDL Input file (extension `.cdb`).

NASTRAN
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to a NASTRAN file (extension `.bdf`).

PATRAN
allows you to specify the surface(s), scalars, and optional loads, based on the kind of finite element analysis selected, to be exported to a PATRAN neutral file (extension `.out`).

RadTherm
allows you to specify the surface(s) for which you want to write data and the method of writing the heat transfer coefficient, to be exported to a PATRAN neutral file (extension `.neu`). This option is available only when the **Energy Equation** is enabled.

Tecplot
allows you to specify the surface(s) and the scalars you want to write, to be exported to a Tecplot file.

Cell Zones
specifies the cell zones for which data is to be written for a CFD-Post compatible, EnSight, or FIELDVIEW file.

Surfaces
specifies the surfaces for which data is to be written for an ABAQUS, ASCII, Data Explorer, I-deas Universal, Mechanical APDL Input, NASTRAN, PATRAN, RadTherm, or Tecplot file.

Quantities
specifies valid functions for output. The attributes of the list are modified based on the active file type. The list may be a single-selection or a multiple-selection list or it may be disabled, depending on the selected **File Type**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Structural Loads
contains optional structural loads that can be written to ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN files. This option is available only when **Structural** analysis is selected.

Force
enables force to be written as a load for a structural analysis.

Pressure
enables pressure to be written as a load for a structural analysis.

Temperature
enables temperature to be written as a load for a structural analysis. This option is available only when the **Energy Equation** is enabled.

Thermal Loads
contains optional thermal loads that can be written to ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN files. This option is available only when **Thermal** analysis is selected.

Temperature
enables temperature to be written as a load for a thermal analysis.

Heat Flux
enables heat flux to be written as a load for a thermal analysis.

Heat Trans Coeff
enables heat transfer coefficient to be written as a load for a thermal analysis.

Location (for ASCII, CGNS, and EnSight Case Gold formats)
specifies the location in the cell from which the values of scalar functions are to be taken.

Node
specifies that data values at the node points are to be exported.

Cell Center
specifies that data values from the cell centers are to be exported.

Analysis (for ABAQUS, I-deas Universal, Mechanical APDL Input, NASTRAN, and PATRAN formats
specifies the finite element analysis intended.

Structural
specifies structural analysis and allows you to select the **Structural Loads** to be written.

Thermal
specifies thermal analysis and allows you to select the **Thermal Loads** to be written.

Delimiter (for ASCII format only)
specifies the delimiter used to separate the data fields.

Comma
specifies comma as the delimiter separating the data fields.

Space
specifies space as the delimiter separating the data fields.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transient (for EnSight Case Gold only)
contains options for exporting transient data.

Transient
enables export of transient data.

Separate Files for Each Timestep
enables writing separate files for each timestep.

Append Frequency
specifies the frequency for appending the data during the solution process.

> **Important**
>
> The **Append Frequency** option is replaced by the **Write Frequency** option when **Separate Files for Each Timestep** is enabled. You can specify the frequency for writing the separate files.

File Name
specifies the root name for the files to be saved.

Format (for EnSight Case Gold and CFD-Post Compatible)
specifies the file format.

Binary
specifies the file format as binary.

ASCII
specifies the file format as ASCII.

Heat Transfer Coefficient (for RadTherm format only)
specifies the basis for the heat transfer coefficient exported.

Flux Based
specifies the flux based method for writing the heat transfer coefficient.

Wall Function
specifies the wall function based method for writing the heat transfer coefficient.

Write Case File (for CFD-Post Compatible only)
specifies whether or not a case file is written with the `.cdat` file.

Write...
opens The Select File Dialog Box (p. 19) for writing the specified function(s) in the specified format.

38.1.57. File/Export/Particle History Data...

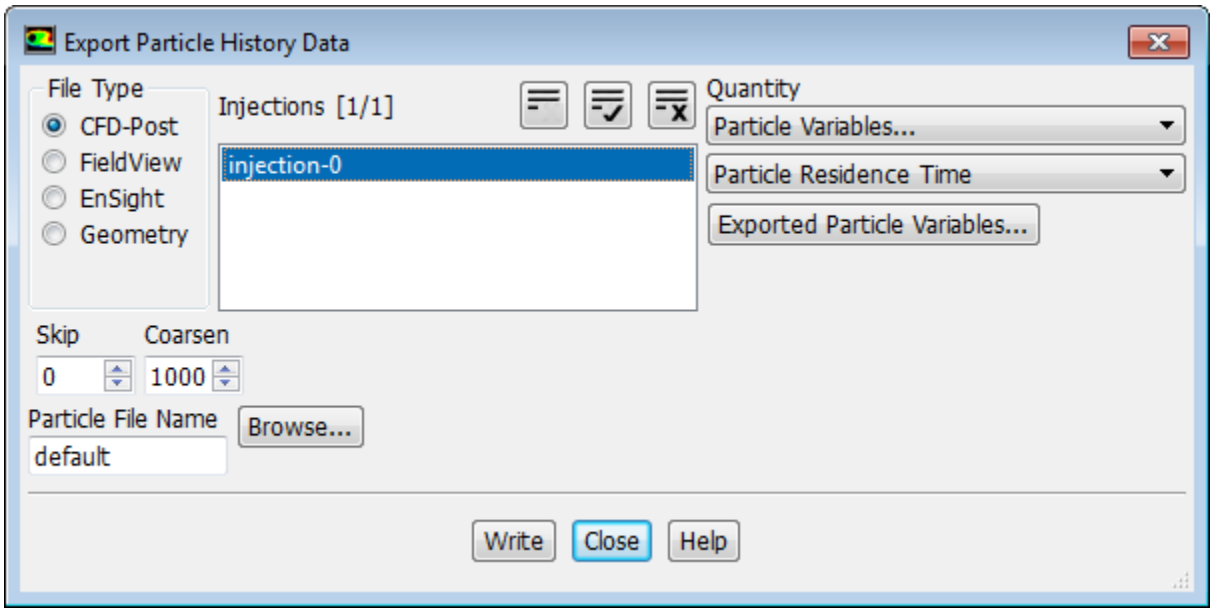
The **File/Export/Particle History Data...** ribbon tab item opens the Export Particle History Data Dialog Box (p. 2648).

38.1.57.1. Export Particle History Data Dialog Box

The **Export Particle History Data** dialog box allows you to export particle history data as your solution progresses. See Exporting Steady-State Particle History Data (p. 84) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File → Export → Particle History Data...



Controls

Type
specifies the type of the file you want to write.

CFD-Post
allows you to write the file in CFD-Post particle tracks format, which can be read in **CFD-Post**.

FieldView
allows you to write the file in **FIELDVIEW** format, which can be read in **FIELDVIEW**.

EnSight
allows you to write the file in **EnSight** format.

Geometry
allows you to write the file in `.ibl` format, which can be read in GAMBIT (not available when **Unsteady Particle Tracking** is enabled in the **Discrete Phase** dialog box, which is opened by clicking **Discrete Phase...** in the **Setting Up Physics** ribbon tab).

Injections
allows you to select the required injection from the list of predefined injections.

Quantity
contains the list of variables for which you can export the particle data.

Skip
allows you to "thin" or "sample" the number of particles that are exported.

Coarsen
reduces the exported file size by reducing the number of points that are written for a given trajectory. This is only valid for steady-state cases.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Particle File Name
allows you to specify the file name/directory for the exported data, using the **Browse...** button.

Encas File Name
is the file name you will specify if you selected **EnSight** under **Type**. Use the **Browse...** button to select the `.encas` file that was created when you exported the file with the **File/Export...** ribbon tab option.

Number of Particle Time Steps
appears when you select **EnSight** under **Type**. The specified number is the number of particle time-steps that are saved to the `.encas` file.

38.1.58. File/Export/During Calculation/Solution Data...

The **File/Export/During Calculation/Solution Data...** ribbon tab item opens the Automatic Export Dialog Box (p. 2530) (transient cases only).

38.1.59. File/Export/During Calculation/Particle History Data...

The **File/Export/During Calculation/Particle History Data...** ribbon tab item opens the Automatic Particle History Data Export Dialog Box (p. 2533) (transient cases only).

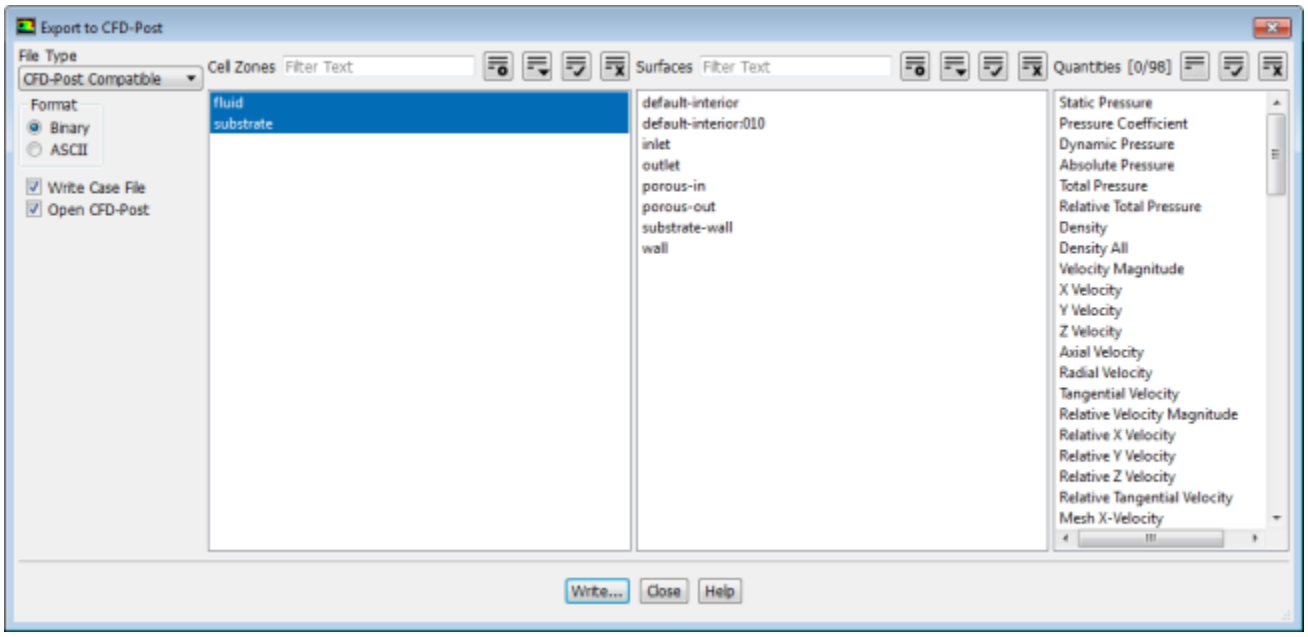
38.1.60. File/Export to CFD-Post...

The **File/Export to CFD-Post...** ribbon tab item opens the Export to CFD-Post Dialog Box (p. 2650).

38.1.60.1. Export to CFD-Post Dialog Box

The **Export to CFD-Post** dialog box allows you to select the quantities that you would like to export to CFD-Post. See Exporting to ANSYS CFD-Post (p. 91) for details.

File → Export to CFD-Post...



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select Quantities
contains a selectable list where you can choose the quantities to export.

Format
allows you to export the `.cdat` file in **Binary** or **ASCII** format.

Write Case File
specifies whether or not a case file is written with the `.cdat` file.

Open CFD-Post
specifies that after the files have been written, a CFD-Post session is opened, with the case and `.cdat` files loaded. CFD-Post will display the results.

Write...
opens the **Select File** dialog box, where you can specify the name and location of the exported files.

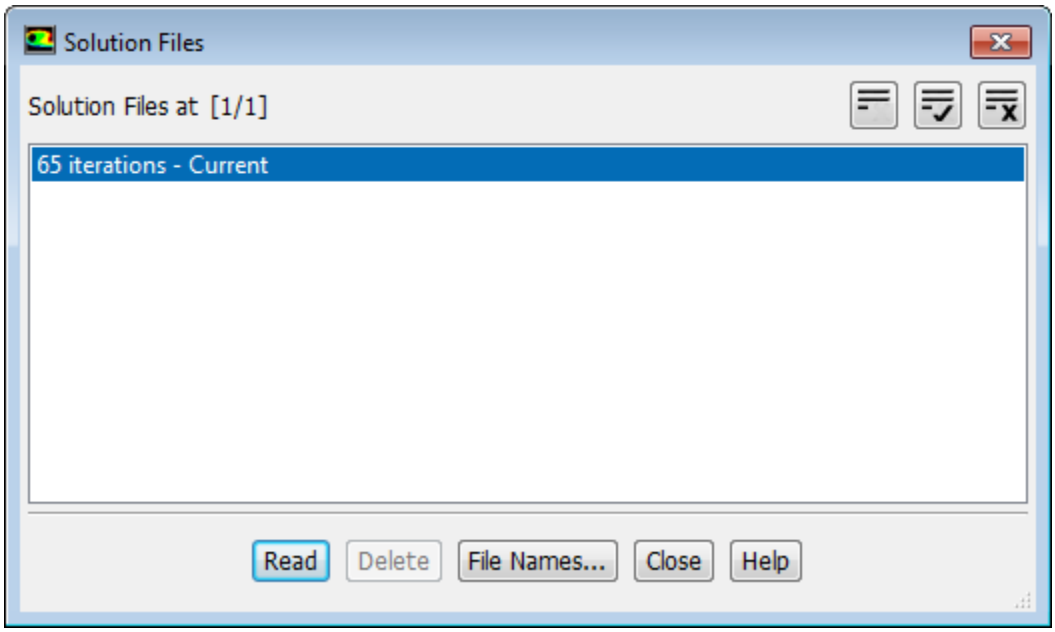
38.1.61. File/Solution Files...

The **File/Solution Files...** ribbon tab item opens the Solution Files Dialog Box (p. 2651).

38.1.61.1. Solution Files Dialog Box

The **Solution Files** dialog box allows you to manage the files that were created through the Autosave Dialog Box (p. 2527). See Managing Solution Files (p. 93) for details.

File → Solution Files...



Controls

Solution Files at
contains a selectable list where you can choose the files to read or delete.

Read
makes the selected file the current file. Note that if more than one file is selected, the **Read** button is disabled. When an earlier solution is made current, the solution files that were generated for a later iteration/time-step will be removed from this list when the calculation continues.

Delete
removes the selected solution files.

File Names...
allows you to obtain information about the solution files and the path of the associated files.

Recover Missing Solution...
Recovers the latest case and data files from the system folder (<*project name*>\dp0\FFF\Fluent\ for analysis system and <*project name*>\dp0\ FLU \Fluent\ for component system) and list them in the **Solution Files at** list. (This option is available only in Fluent used under Workbench.)

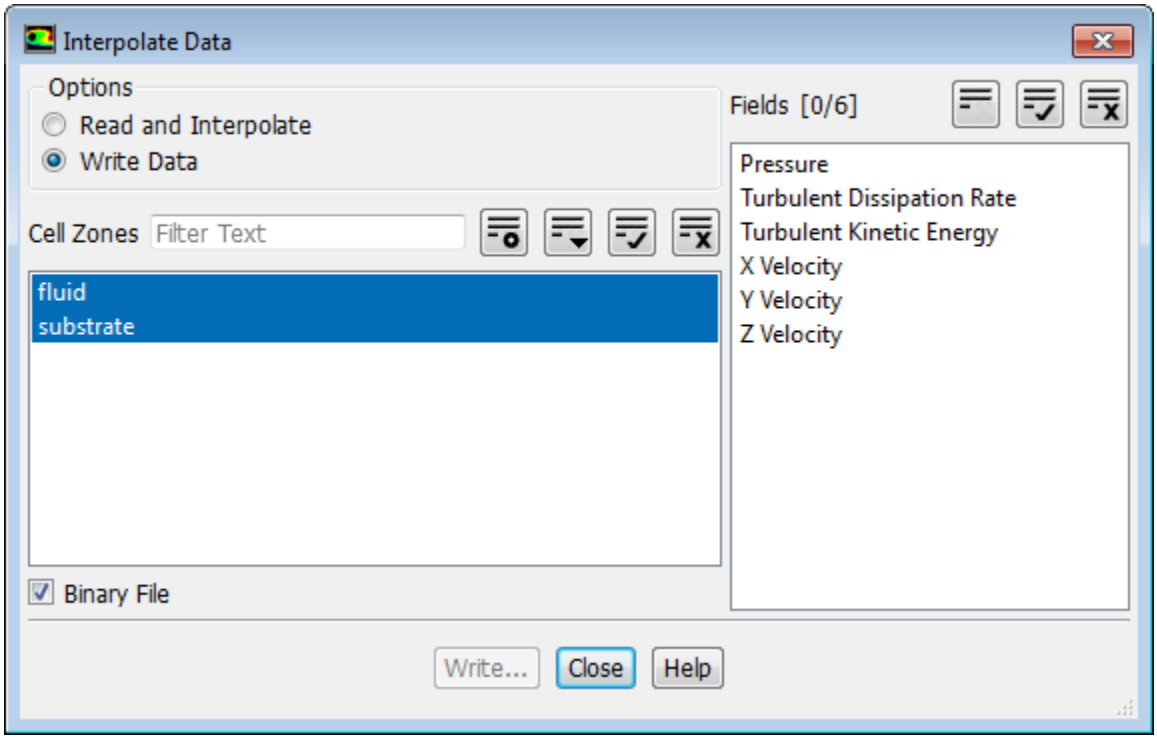
38.1.62. File/Interpolate...

The **File/Interpolate...** ribbon tab item opens the Interpolate Data Dialog Box (p. 2652).

38.1.62.1. Interpolate Data Dialog Box

The **Interpolate Data** dialog box allows you to interpolate solution data from one mesh to another. See Mesh-to-Mesh Solution Interpolation (p. 94) for details.

File → Interpolate...



Controls

Options
contains the interpolation options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Read and Interpolate
allows you to read and interpolate solution data onto the current mesh.

Write Data
allows you to write an interpolation file for the solution data to be interpolated onto another mesh.

Cell Zones
is a list of cell zones that can be selected.

Binary File
allows you to write binary interpolation files. This option is available only when **Write Data** is selected under **Options**.

Fields
is a list of all available data fields that can be selected. This list is available only when **Write Data** is selected under **Options**.

Read...
opens The Select File Dialog Box (p. 19), in which you can specify the file to be read. This button is available only when the **Read and Interpolate** option is selected.

Write...
opens The Select File Dialog Box (p. 19), in which you can specify a name for the file to be saved and then save the file. This button replaces the **Read...** button when the **Write Data** option is selected.

38.1.63. File/FSI Mapping/Volume...

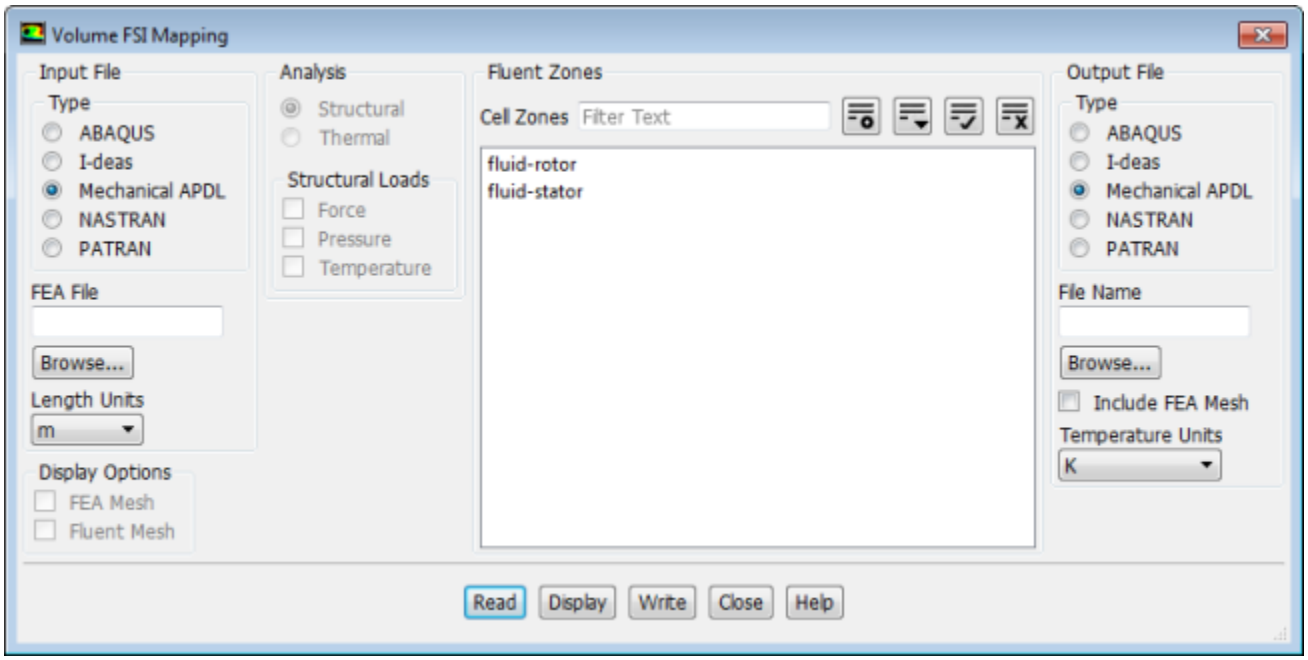
The **File/FSI Mapping/Volume...** ribbon tab item opens the Volume FSI Mapping Dialog Box (p. 2653).

38.1.63.1. Volume FSI Mapping Dialog Box

The **Volume FSI Mapping** dialog box allows you to map cell data for a given geometry from an ANSYS Fluent file onto a file with a different mesh and format. See Mapping Data for Fluid-Structure Interaction (FSI) Applications (p. 97) for a complete description of how to use the dialog box.

File → FSI Mapping → Volume...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Input File

contains parameters related to the input file.

Type

contains the options for the format of the input mesh file.

ABAQUS

specifies that an ABAQUS file will be used as the input mesh file (extension `.inp`).

I-deas

specifies that an I-deas file will be used as the input mesh file (extension `.unv`).

Mechanical APDL

specifies that a Mechanical APDL file will be used as the input mesh file (extension `.cdb` or `.neu`).

NASTRAN

specifies that a NASTRAN file will be used as the input mesh file (extension `.bdf`).

PATRAN

specifies that a PATRAN file will be used as the input mesh file (extension `.neu`, `.out`, or `.pat`).

FEA File

specifies the name of the input mesh file (see the **Input File Type** descriptions for associated file extensions). If the file is not in the current working folder, include the full path to the folder where it is located.

Browse...

opens The Select File Dialog Box (p. 19), which you can use to specify the input mesh file instead of entering it in the **Input File** text-entry box.

Length Units

specifies the unit of length used in the input file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Display Options
allows you to choose either the **FEA Mesh** or the **ANSYS Fluent Mesh** (or both).

Analysis
contains the options for the kind of data to be mapped.

Structural
specifies that data fields relevant for a structural analysis will be mapped.

Thermal
specifies that data fields relevant for a thermal analysis will be mapped.

Structural Loads
consists of a list of available loads, including **Force**, **Pressure**, and **Temperature**.

Fluent Zones
contains a list of available cell zones from the current ANSYS Fluent file from which cell data will be mapped.

Output File
contains the options for the format of the file that will be created from the input mesh file and the mapped data.

Type
contains the options for the format of the output mesh file.

ABAQUS
specifies that an ABAQUS file will be used as the output mesh file (extension `.inp`).

I-deas
specifies that an I-deas file will be used as the output mesh file (extension `.unv`).

Mechanical APDL
specifies that a Mechanical APDL file will be used as the output mesh file (extension `.cdb`).

NASTRAN
specifies that a NASTRAN file will be used as the output mesh file (extension `.bdf`).

PATRAN
specifies that a PATRAN file will be used as the output mesh file (extension `.out`).

File Name
specifies the name of the input mesh file (see the **Output File** descriptions for associated file extensions). If the file is not in the current working folder, include the full path to the folder where it is located.

Browse...
opens The Select File Dialog Box (p. 19), which you can use to specify the input mesh file instead of entering it in the **Input File** text-entry box.

Include FEA Mesh
includes additional FEA information like node/element information in the exported output file.

Temperature Units
specifies the unit of temperature when mapping temperature for a structural analysis or any variable for a thermal analysis.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Read
reads the input file into memory.

Display
displays the selected mesh in the graphics window.

Write
writes an output file in which the selected ANSYS Fluent cell data is mapped onto the input mesh file.

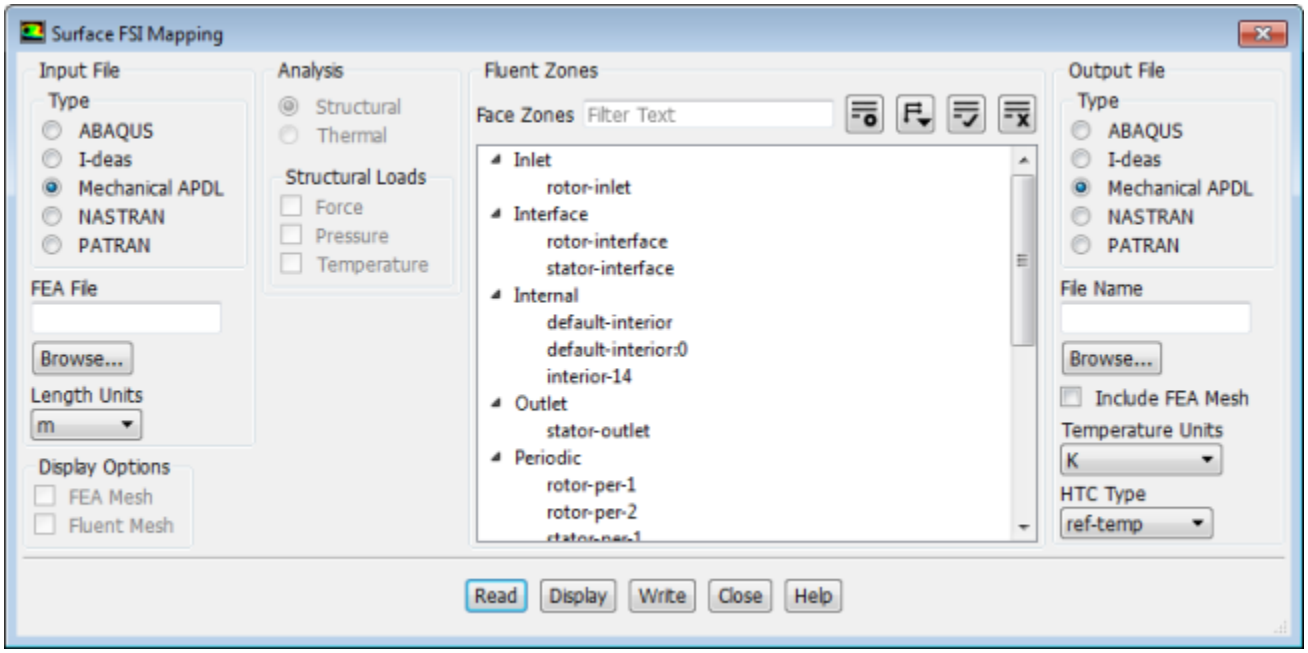
38.1.64. File/FSI Mapping/Surface...

The **File/FSI Mapping/Surface...** ribbon tab item opens the Surface FSI Mapping Dialog Box (p. 2656).

38.1.64.1. Surface FSI Mapping Dialog Box

The **Surface FSI Mapping** dialog box allows you to map face data for a given geometry from an ANSYS Fluent file to a file with a different mesh and format. See Mapping Data for Fluid-Structure Interaction (FSI) Applications (p. 97) for a complete description of how to use the dialog box.

File → FSI Mapping → Surface...



Controls

Input File
contains parameters related to the input file.

Type
contains the options for the format of the input mesh file.

ABAQUS
specifies that an ABAQUS file will be used as the input mesh file (extension `.inp`).

I-deas
specifies that an I-deas file will be used as the input mesh file (extension `.unv`).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mechanical APDL
specifies that a Mechanical APDL file will be used as the input mesh file (extension `.cdb` or `.neu`).

NASTRAN
specifies that a NASTRAN file will be used as the input mesh file (extension `.bdf`).

PATRAN
specifies that a PATRAN file will be used as the input mesh file (extension `.neu`, `.out`, or `.pat`).

FEA File
specifies the name of the input mesh file (see the **Input File Type** descriptions for associated file extensions). If the file is not in the current working folder, include the full path to the folder where it is located.

Browse...
opens The Select File Dialog Box (p. 19), which you can use to specify the input mesh file instead of entering it in the **Input File** text-entry box.

Length Units
specifies the unit of length used in the input file.

Display Options
allows you to choose either the **FEA Mesh** or the **ANSYS Fluent Mesh** (or both).

Analysis
contains the options for the kind of data to be mapped.

Structural
specifies that data fields relevant for a structural analysis will be mapped.

Thermal
specifies that data fields relevant for a thermal analysis will be mapped.

Structural Loads
consists of a list of available loads, including **Force**, **Pressure**, and **Temperature**.

Fluent Zones
contains a list of available face zones from the current ANSYS Fluent file from which cell data will be mapped.

Output File
contains the options for the format of the file that will be created from the input mesh file and the mapped data.

Type
contains the options for the format of the output mesh file.

ABAQUS
specifies that an ABAQUS file will be used as the output mesh file (extension `.inp`).

I-deas
specifies that an I-deas file will be used as the output mesh file (extension `.unv`).

Mechanical APDL
specifies that a Mechanical APDL file will be used as the output mesh file (extension `.cdb`).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NASTRAN
specifies that a NASTRAN file will be used as the output mesh file (extension `.bdf`).

PATRAN
specifies that a PATRAN file will be used as the output mesh file (extension `.out`).

File Name
specifies the name of the input mesh file (see the **Output File** descriptions for associated file extensions). If the file is not in the current working folder, include the full path to the folder where it is located.

Browse...
opens The Select File Dialog Box (p. 19), which you can use to specify the input mesh file instead of entering it in the **Input File** text-entry box.

Include FEA Mesh
includes additional FEA information like node/element information in the exported output file.

Temperature Units
specifies the unit of temperature when mapping temperature for a structural analysis or any variable for a thermal analysis.

HTC Type
specifies the means of calculating the heat transfer coefficient.

ref-temp
uses a temperature equal to the reference temperature to calculate the heat transfer coefficient.

cell-temp
uses a temperature equal to the temperature of the cell adjacent to the face to calculate the heat transfer coefficient.

wall-func-htc
calculates h_{eff} using Equation 33.55 (p. 2001). Note that this option has the same definition as the field variable **Wall Func. Heat Tran. Coef.**, as described in Alphabetical Listing of Field Variables and Their Definitions (p. 1957).

Read
reads the input file into memory.

Display
displays the selected mesh in the graphics window.

Write
writes an output file in which the ANSYS Fluent data has been mapped to the mesh of the input file.

38.1.65. File/Save Picture...

The **File/Save Picture...** ribbon tab item opens the Save Picture Dialog Box (p. 2568).

38.1.66. File/Data File Quantities...

The **File/Data File Quantities...** ribbon tab item opens the Data File Quantities Dialog Box (p. 2529).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

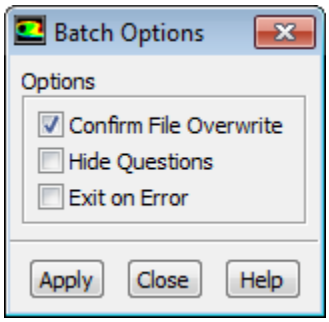
38.1.67. File/Batch Options...

The **File/Batch Options...** ribbon tab item opens the Batch Options Dialog Box (p. 2659).

38.1.67.1. Batch Options Dialog Box

The **Batch Options** dialog box allows you to select options to suppress interactive dialog boxes from ANSYS Fluent while running a case in batch mode. See Batch Execution Options in the Getting Started Guide for details.

File → Batch Options...



Controls

Confirm File Overwrite
determines whether ANSYS Fluent confirms a file overwrite. This option is enabled by default.

Hide Questions
allows you to hide **Question** dialog boxes. This option is disabled by default.

Exit on Error
allows you to automatically exit from batch mode when an error occurs. This option is disabled by default.

When run in batch mode through the command prompt or a journal file with **Exit on Error** enabled, Fluent will exit under the following circumstances:

- Normal run termination upon reaching the end of a journal (return value `0`)
- Error returned during scripted text command execution (return value `1`)
- Unexpected input (wrong type) to text command (return value `1`)
- Licensing error (return value 2)

If an invalid text command is entered, Fluent will not exit, but proceed to the next text input.

Note that in Windows you must start Fluent with the `-wait` command line option.

38.1.68. File/Exit

The **File/Exit** ribbon tab item is used to exit from the current solver session.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2. Dialog Boxes Available from the Ribbon

The dialog boxes described in this section can be accessed through the ribbon, from the tabs other than the **File** ribbon tab.

38.2.1. 1D Simulation Library Dialog Box
38.2.2. Activate Cell Zones Dialog Box
38.2.3. Adaption Display Options Dialog Box
38.2.4. Adjacency Dialog Box
38.2.5. Animation Definition Dialog Box
38.2.6. Animation Recording Options Dialog Box
38.2.7. Anisotropic Adaption Dialog Box
38.2.8. Auto Create Options Dialog Box
38.2.9. Auto Partition Mesh Dialog Box
38.2.10. Boundary Adaption Dialog Box
38.2.11. Compiled UDFs Dialog Box
38.2.12. Contours Dialog Box
38.2.13. Convergence Conditions Dialog Box
38.2.14. Create/Edit Mesh Interfaces Dialog Box
38.2.15. Custom Field Function Calculator Dialog Box
38.2.16. Custom Laws Dialog Box
38.2.17. Deactivate Cell Zones Dialog Box
38.2.18. Define Control Points Dialog Box
38.2.19. Delete Cell Zones Dialog Box
38.2.20. DPM Report Definition Dialog Box
38.2.21. DPM Source Report Definition
38.2.22. Drag Report Definition Dialog Box
38.2.23. DTRM Graphics Dialog Box
38.2.24. DTRM Rays Dialog Box
38.2.25. Edit Mesh Interfaces Dialog Box
38.2.26. Edit Report File Dialog Box
38.2.27. Edit Report Plot Dialog Box
38.2.28. Execute on Demand Dialog Box
38.2.29. Expression Report Definition Dialog Box
38.2.30. Field Function Definitions Dialog Box
38.2.31. Flux Report Definition Dialog Box
38.2.32. Fuse Face Zones Dialog Box
38.2.33. Geometry Based Adaption Controls Dialog Box
38.2.34. Geometry Based Adaption Dialog Box
38.2.35. Gradient Adaption Dialog Box
38.2.36. Import Particle Data Dialog Box
38.2.37. Imprint Surface Dialog Box
38.2.38. Improve Mesh Dialog Box
38.2.39. Injections Dialog Box
38.2.40. Input Summary Dialog Box
38.2.41. Interface Options Dialog Box
38.2.42. Interpreted UDFs Dialog Box
38.2.43. Iso-Clip Dialog Box
38.2.44. Iso-Surface Dialog Box
38.2.45. Iso-Value Adaption Dialog Box
38.2.46. Lift Report Definition Dialog Box
38.2.47. Line/Rake Surface Dialog Box
38.2.48. Manage Adaption Registers Dialog Box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.49. Merge Zones Dialog Box
38.2.50. Mesh Adaption Controls Dialog Box
38.2.51. Mesh Interfaces Dialog Box
38.2.52. Mesh Morpher/Optimizer Dialog Box
38.2.53. MiniVAS Settings Dialog Box
38.2.54. Mixing Planes Dialog Box
38.2.55. Moment Report Definition Dialog Box

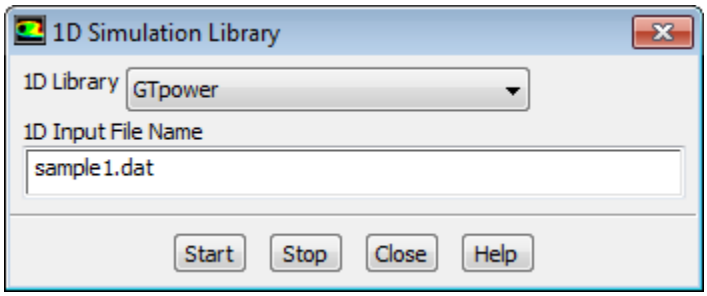
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.101. User Defined Report Definition Dialog Box
38.2.102. User-Defined Scalars Dialog Box
38.2.103. Vectors Dialog Box
38.2.104. Video Control Dialog Box
38.2.105. V-LAN Settings Dialog Box
38.2.106. Volume Adaption Dialog Box
38.2.107. Volume Report Definition Dialog Box
38.2.108. Warning Dialog Box
38.2.109. Yplus/Ystar Adaption Dialog Box
38.2.110. Zone Surface Dialog Box

38.2.1. 1D Simulation Library Dialog Box

The **1D Simulation Library** dialog box allows you to set parameters related to coupling between ANSYS Fluent and GT-POWER or WAVE. See Coupling Boundary Conditions with GT-POWER (p. 451) or Coupling Boundary Conditions with WAVE (p. 456) for details about the items below.

User Defined → **Model Specific** → **1D Coupling...**



Controls

1D Library
specifies the type of library to be used. (Currently only **GTpower** and **WAVE** are available.)

1D Input File Name
specifies the name of the GT-POWER or WAVE input file.

Start
starts up GT-POWER or WAVE and generates ANSYS Fluent user-defined functions for each boundary in the input file.

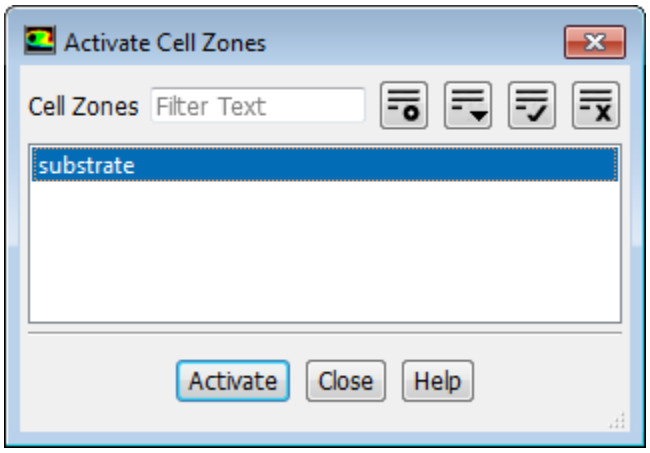
Stop
unlinks the shared library.

38.2.2. Activate Cell Zones Dialog Box

The **Activate Cell Zones** dialog box allows you to activate a single cell zone or multiple zones. See Activating Zones (p. 221) for details.

Setting Up Domain → **Zones** → **Activate...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

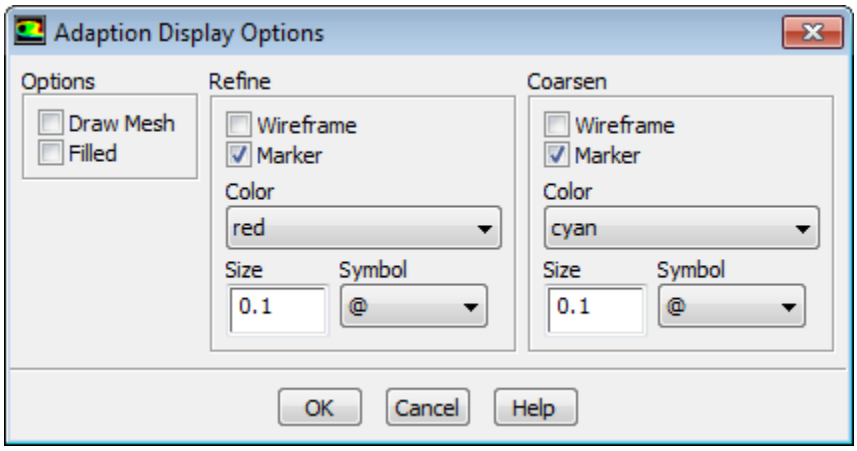
Cell Zones
contains a list of cell zones from which you can select the zone to be activated.

Activate
activates the selected cell zones.

38.2.3. Adaption Display Options Dialog Box

The **Adaption Display Options** dialog box allows you to customize the display of adaption or mask registers. See Adaption Display Options (p. 1704) for details about the items below.

Setting Up Domain → Adapt → More → Display Options...



Controls

Options
contains check buttons that control the drawing of the mesh and the type of graphical tool used to display flagged cells.

Draw Mesh
toggles the ability to draw the mesh with the adaption display. This command opens the Mesh Display Dialog Box (p. 2163), which allows you to select the desired surface or zone meshes to be displayed with the markings.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Filled
toggles the solid shading of the cell wireframe.

Refine
contains options related to the display of cells marked for refinement.

Wireframe
toggles the display of the cell wireframe for cells flagged for refinement.

Marker
toggles the display of the cell marker for cells flagged for refinement.

Color
is a drop-down list of colors for the wireframe or marker for the cells marked for refinement.

Size
is a real number entry for the size of the refine cell marker. A symbol of size 1.0 is 3.0% of the height of the display screen.

Symbol
is a drop-down list of symbols that can be used for the refine cell marker.

Coarsen
contains options related to the display of cells marked for refinement.

Wireframe
toggles the display of the cell wireframe for cells flagged for coarsening.

Marker
toggles the display of the cell marker for cells flagged for coarsening.

Color
is a drop-down list of colors for the wireframe or marker for the cells marked for coarsening.

Size
is a real number entry for the size of the coarsen cell marker. A symbol of size 1.0 is 3.0% of the height of the display screen.

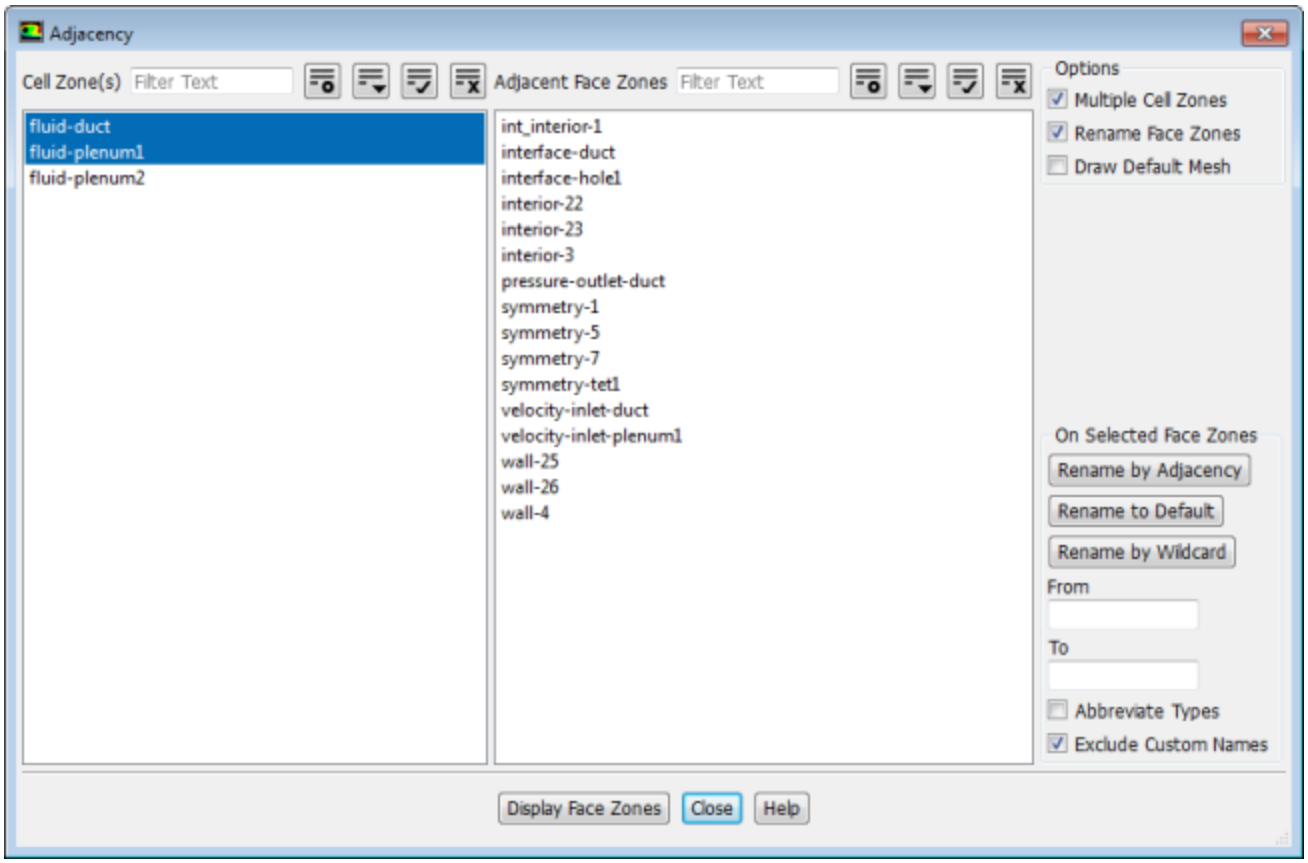
Symbol
is a drop-down list of symbols that can be used for the coarsen cell marker.

38.2.4. Adjacency Dialog Box

The **Adjacency** dialog box allows you to identify, display, and rename face zones based on their adjacency to a selected cell zone. See Managing Adjacent Zones (p. 224) for details.

Setting Up Domain → Zones → Adjacency...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Cell Zone(s)
contains a list of the cell zones for which you can find adjacent face zones.

Adjacent Face Zones
contains a list of the face zones that are adjacent to the selected cell zones.

Options

Multiple Cell Zones
allows you to select multiple cell zones at once. The zones listed in **Adjacent Face Zones** will be the union of all zones adjacent to the selected cell zones.

Rename Face Zones
allows you to rename selected face zones based on adjacency or zone type.

Draw Default Mesh
brings up the Mesh Display Dialog Box (p. 2163) where you can specify zones of the mesh to be permanently displayed as you display or hide face zones from within the **Adjacency** dialog box. This can be helpful in cases where the mesh is very complex. If this option is not enabled, only the zones selected in **Adjacent Face Zones** will be displayed when you click **Display Face Zones**.

On Selected Face Zones
contains controls for renaming face zones that are selected in **Adjacent Face Zones**. For details on the renaming methods, refer to Renaming Zones Using the Adjacency Dialog Box (p. 225).

Rename by Adjacency
renames the selected face zones incorporating the name of the adjacent cell zone and the face zone type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rename to Default
renames the selected face zones with default names based on the face zone type and, if necessary to avoid duplicate names, the zone id.

Rename by Wildcard
renames the selected face zones based on a pattern match string in the **From** field and a replacement string in the **To** field.

Abbreviate Types
uses abbreviations for the zone types when renaming rather than the full zone type text.

Exclude Custom Names
excludes from renaming any zones that do not match a recognized naming pattern. This can be useful to prevent inadvertently replacing a meaningful name.

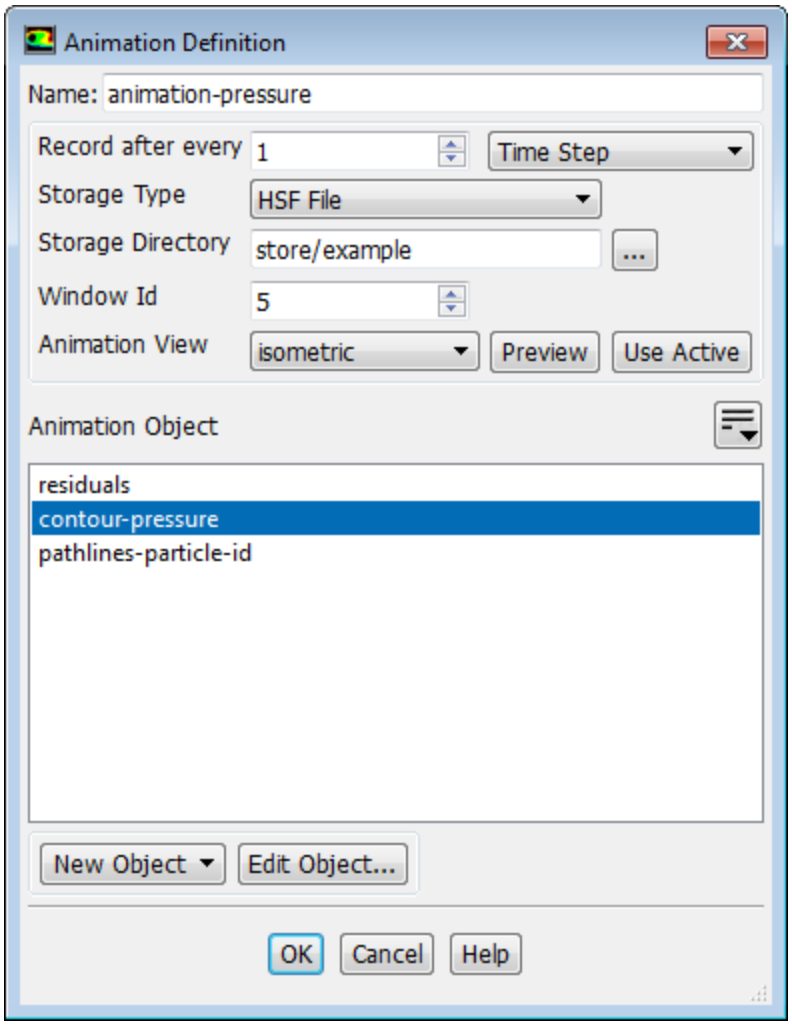
Displace Face Zones
displays the face zones selected in **Adjacent Face Zones**.

38.2.5. Animation Definition Dialog Box

The **Animation Definition** dialog box allows you to specify a graphics object that will be captured during the solution calculation so that it may be played back as an animation during postprocessing.

Solving → Activities → Create → Solution Animations...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
name of the animation definition.

Record after every
specifies the frequency that images are captured during the calculation. You can select whether the frequency is **Iteration** or **Time Step** (transient only) from the drop-down.

Storage Type
drop-down list with the available formats for storing the animation images.

In Memory
the image files associated with the animation will lost when you exit Fluent.

PPM Image
Fluent will save the animation images in PPM Image format (`.cxa`), which is 2D.

HSF File
Fluent will save the animation images in HSF file format (`.hsf`), which is 3D.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Storage Directory
shows the location where the animation images will be stored if the **Storage Type** is set to **PPM Image** or **HSF File**.

Window ID
indicates the window where the solution animation images will be displayed when the solution is calculating.

Animation View
specifies the animation object orientation that will be used when the animation images are capture during the calculation.

views drop-down
list with all of the defined views.

Preview
displays the selected animation object in the graphics window specified by **Window ID**.

Use Active
saves the current view in the active graphics window and automatically selects it for use in the animation definition.

Animation Object
lists the defined graphics objects that may be selected for animation.

New Object
drop-down list allowing you to create new graphics objects for animating.

- **Mesh...** opens the Mesh Display Dialog Box (p. 2163).
- **Contours...** opens the Contours Dialog Box (p. 2676).
- **Vectors...** opens the Vectors Dialog Box (p. 2831).
- **Pathlines...** opens the Pathlines Dialog Box (p. 2771).
- **Particle Tracks...** opens the Particle Tracks Dialog Box (p. 2761).
- **Scene...** opens Figure 31.26: The Scene Dialog Box (p. 1781).
- **XY Plot...** opens the Solution XY Plot Dialog Box (p. 2595).
- **Report Plot...** opens the New Report Plot Dialog Box (p. 2755).

Edit Object...
allows you to edit the selected graphics object.

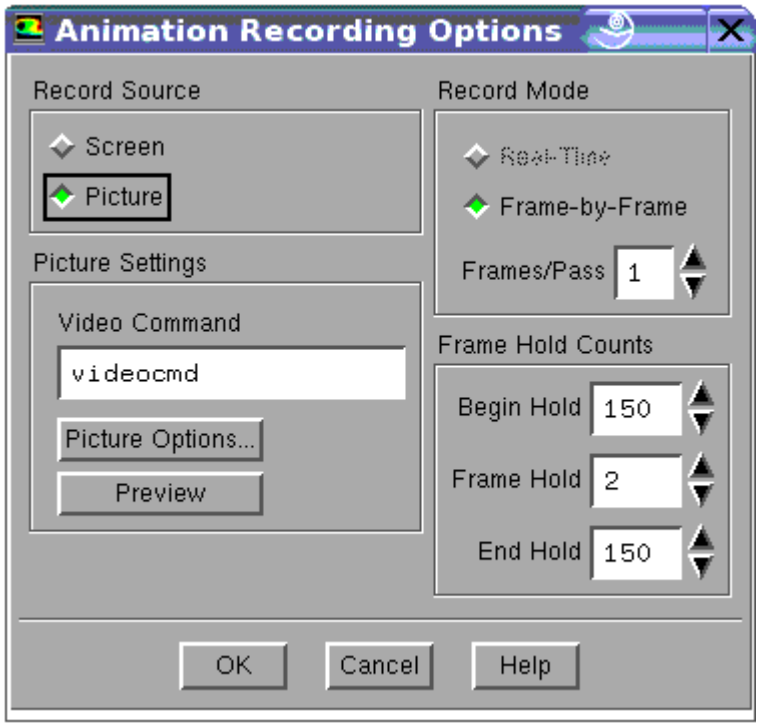
OK
creates the animation definition and/or saves settings changes and closes the dialog box.

38.2.6. Animation Recording Options Dialog Box

The **Animation Recording Options** dialog box allows you to set specific options for recording animations to video. An animation is created using the Animate Dialog Box (p. 2567).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Animation Recording Options** dialog box is opened from the Video Control Dialog Box (p. 2833).



Controls

Record Source
identifies the video source used during a recording session.

Screen
informs ANSYS Fluent that the computer's video hardware will send all or a portion of the computer screen as a video signal to the VTR. This option assumes your computer's video system includes a scan converter and associated software that converts the computer RGB signal to a video signal. You are responsible for setting up the scan converter and sending the video signal to the VTR.

Picture
instructs ANSYS Fluent to create a picture of each frame of animation and send the picture file to the computer's video hardware using a system command. This option assumes that your computer's video system includes a frame buffer that can store an image and send it as a video signal to the video recording system.

Picture Settings
is used in conjunction with the **Picture** record source option.

Video Command
identifies the shell script command file used to send a picture file to the video frame buffer. The default setting is `videocmd`, which is a shell script that is included in your ANSYS Fluent distribution. It is located in *path* `/ansys_inc/v181/fluent/bin`, where *path* is the directory in which you have placed the release directory. This shell script will run your system's command to send an image file to the video frame buffer. The script `videocmd` is set up to call the SGI system command `memtovid`. If you have a different system, you must copy the shell script `videocmd` to a new file and modify it to perform the proper task on your system (see the comments in `videocmd` for details).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Picture Options...
displays the Save Picture Dialog Box (p. 2568), which allows you to set up the picture format supported by your video frame buffer. If you choose to perform a window dump to create the picture file, the default window dump command used will also be `videocmd`. You can change this setting to use your own command. After setting the picture options, click **Apply** instead of **Save...** in the Save Picture Dialog Box (p. 2568) to effect the change.

Preview
will send a test picture of the current graphics picture to the video frame buffer. This can be used to check the image on your video recording system's monitor to see if the image size and color levels are acceptable.

Record Mode
specifies the method used to record the animation.

Real-Time
can be used if the animation playback speed is fast enough to provide a reasonably smooth animation in real-time. This is only available if the selected record source is **Screen**. In this mode, ANSYS Fluent will simply turn VTR recording on, play the animation, then stop the recording.

Frame-By-Frame
is used to produce a higher-quality video animation by recording one frame at a time. For each animation frame, this method will 1) play the frame on the screen (and generate the picture file, if needed), 2) preroll the VTR, and 3) record the frame. If the animation has 50 frames, this procedure is repeated 50 times, that is, 50 record passes are made. This is the recommended method, because the real-time playback of the animation will usually be too slow and choppy.

Frames/Pass
is used in conjunction with **Frame-By-Frame** recording to try and speed up this process, if possible. It specifies the number of animation frames recorded to tape per record pass. If the animation is long enough (200 frames or more), you can try setting this value to 2 or higher. For example, if you set this value to 2 for a 202-frame animation, it will record animation frame 1 during the first pass, frames 2 and 102 during the second pass, frames 3 and 103 during the third pass, and so on. This is possible only if the animation frames can be rendered in time to be inserted onto the tape during a record pass, so use this setting with caution.

Frame Hold Counts
specifies the number of video frames to hold an animation frame during recording. The video standard NTSC has a frame rate of 30 frames/sec. At that rate, a 150-frame animation will take only 5 seconds to play. To stretch out the animation, you can record the same animation frame over 2 or more video frames.

Begin Hold
specifies the number of video frames to hold the first animation frame. It helps to hold the first frame for about 5 seconds (150 video frames) so that the viewer can get accustomed to the picture before the animation begins.

Frame Hold
specifies the number of video frames to hold each animation frame, other than the first and last. To slow down your recorded animation, try setting this value to 2 or 3.

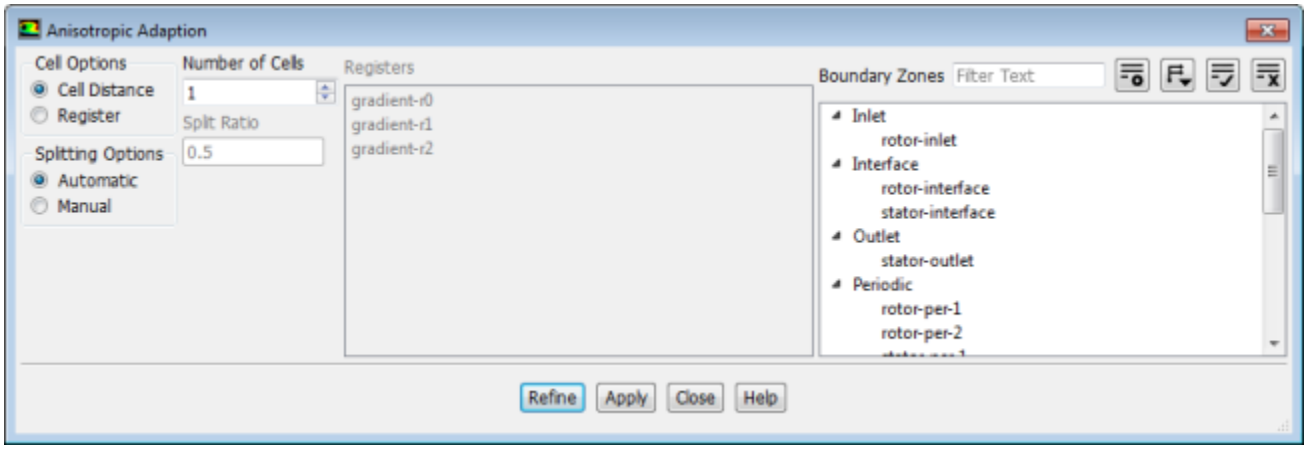
End Hold
specifies the number of video frames to hold the last animation frame. You may want to hold the last animation frame for about 5 seconds to provide closure.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.7. Anisotropic Adaption Dialog Box

The **Anisotropic Adaption** dialog box allows you to perform anisotropic adaption for certain cell types. See Anisotropic Adaption (p. 1697) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Anisotropic...



Controls

Cell Options
controls the marking of boundary layer cells.

Cell Distance
indicates adaption using the distance of the marked cell to the boundary zone.

Register
indicates adaption using an existing register.

Splitting Options
control how the splitting ratio is computed.

Automatic
allows the ratio to be computed automatically from the mesh.

Manual
allows you to enter a specific value for the ratio in the **Split Ratio** field.

Number of Cells
indicates the number of cells to be adapted and marked (available only when the **Cell Distance** option is enabled).

Split Ratio
allows you to specify a value for the split ratio (available only when the **Manual** splitting option is enabled).

Registers
provides a list of existing registers (available only when the **Register** option is enabled).

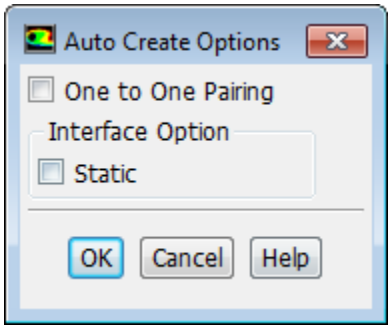
Boundary Zones
contains a list of available boundary zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refine
refines the marked cells.

38.2.8. Auto Create Options Dialog Box

The **Auto Create Options** dialog box allows you to define settings that you want applied to the mesh interfaces that are created through the automatic method (for additional information, see Using a Non-Conformal Mesh in ANSYS Fluent (p. 164)). It is opened by clicking the **Options...** button in the **Unassigned Interface Zones** group box of the Mesh Interfaces Dialog Box (p. 2732).



Controls

One to One Pairing
specifies that the resulting mesh interfaces have a single zone assigned to each side. Using this option may decrease your computational expense and help with troubleshooting later on, though it may produce a larger number of mesh interfaces for you to manage.

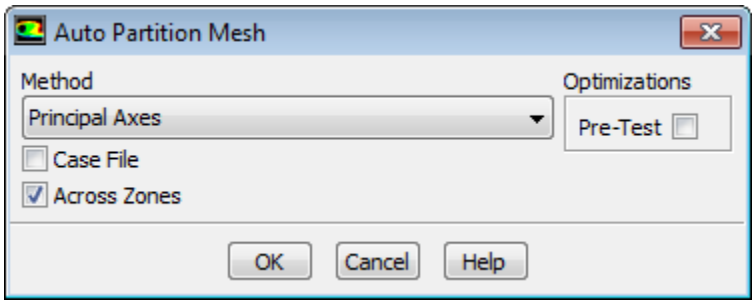
Interface Option
contains an option related to the interface type.

Static
reduces the memory usage and processing time for interface creation (as well as for solution), especially when you are creating interfaces using many unassigned interface zones. This option will only produce correct results if the interface zones do not move or deform relative to each other at the interfaces.

38.2.9. Auto Partition Mesh Dialog Box

The **Auto Partition Mesh** dialog box allows you to set the parameters for automatic partitioning when reading an unpartitioned mesh into the parallel solver. See Partitioning the Mesh Automatically (p. 2031) for details.

Parallel → General → Auto Partition...



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Method

contains a drop-down list of the recursive partition methods that can be used to create the mesh partitions. The choices include the **Cartesian Axes**, **Cartesian Strip**, **Cartesian X-Coordinate**, **Cartesian Y-Coordinate**, **Cartesian Z-Coordinate**, **Cartesian R Axes**, **Cartesian RX-Coordinate**, **Cartesian RY-Coordinate**, **Cartesian RZ-Coordinate**, **Cylindrical Axes**, **Cylindrical R-Coordinate**, **Cylindrical Theta-Coordinate**, **Cylindrical Z-Coordinate**, **Metis**, **Polar Axes**, **Polar R-Coordinate**, **Polar Theta-Coordinate**, **Principal Axes**, **Principal Strip**, **Principal X-Coordinate**, **Principal Y-Coordinate**, **Principal Z-Coordinate**, **Spherical Axes**, **Spherical Rho-Coordinate**, **Spherical Theta-Coordinate**, and **Spherical Phi-Coordinate** techniques, which are described in Mesh Partitioning Methods (p. 2046).

Case File

allows you to use a valid existing partition section in a case file (that is, one where the number of partitions in the case file divides evenly into the number of compute nodes). You need to turn off the **Case File** option only if you want to change other parameters in the **Auto Partition Mesh** dialog box.

Across Zones

allows partitions to cross zone boundaries (the default). If turned off, it will restrict partitioning to within each cell zone. This is recommended *only* when cells in different zones require significantly different amounts of computation during the solution phase, for example if the domain contains both solid and fluid zones.

Optimizations

contains an option to enable pre-testing.

Pre-Test

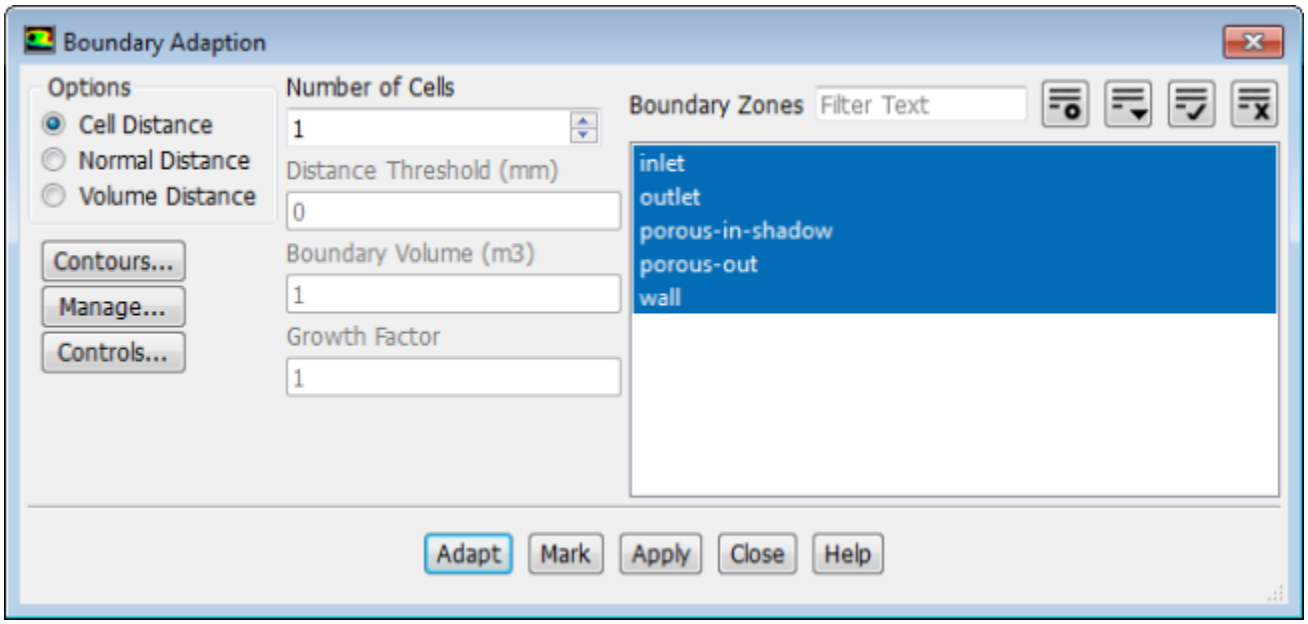
instructs Fluent to test all coordinate directions and choose the one which yields the fewest partition interfaces for the final bisection. Note that this option is available only when you choose **Principal Axes** or **Cartesian Axes** as the partitioning method.

38.2.10. Boundary Adaption Dialog Box

The **Boundary Adaption** dialog box allows you to mark or refine boundary cells on selected boundary zones. See Boundary Adaption (p. 1685) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Boundary...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains three different methods for boundary adaption:

Cell Distance
enables adaption based on a cell's distance from the boundary, measured in number of cells. See Boundary Adaption Based on Number of Cells (p. 1686) for details.

Normal Distance
enables adaption based on a cell's normal distance from the boundary. See Boundary Adaption Based on Normal Distance (p. 1686) for details.

Volume Distance
enables adaption based on a target boundary volume and growth factor. See Boundary Adaption Based on Target Boundary Volume (p. 1687) for details.

Contours...
opens the Contours Dialog Box (p. 2676), which you can use to determine the appropriate parameters for the boundary adaption.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Number of Cells
sets the maximum boundary cell distance for adaption (used with the **Cell Distance** option.

Distance Threshold
sets the maximum normal distance for adaption (used with the **Normal Distance** option).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Boundary Volume
sets the boundary volume $V_{boundary}$ in Equation 29.1 (p. 1687) (used with the **Volume Distance** option).

Growth Factor
sets the exponential growth factor α in Equation 29.1 (p. 1687) (used with the **Volume Distance** option).

Boundary Zones
contains a selectable list of zones on which you can refine. The boundary cells associated with the zones that you select will be refined.

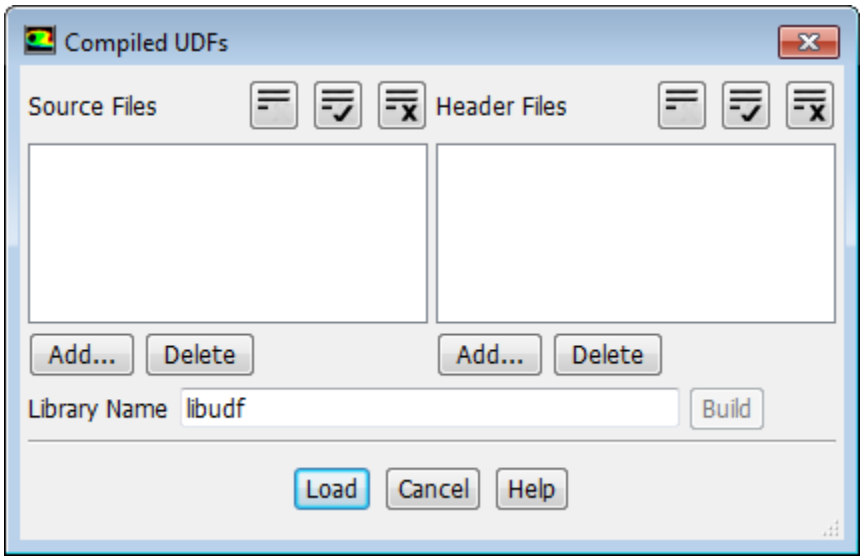
Adapt
refines the cells with edges/faces on the zones selected in the **Boundary Zones** list.

Mark
marks the boundary cells associated with the zones selected in the **Boundary Zones** list for refinement. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

38.2.11. Compiled UDFs Dialog Box

The **Compiled UDFs** dialog box allows you to open a library of compiled user-defined functions. See the separate Fluent Customization Manual for details.

User Defined → User Defined → Functions → Compiled...



Controls

Source Files
contains a list of source files.

Header Files
contains a list of header files.

Add...
opens the **Select File** dialog box.

Delete
deletes the selected file from the list.

Library Name
specifies the name of the library to be created.

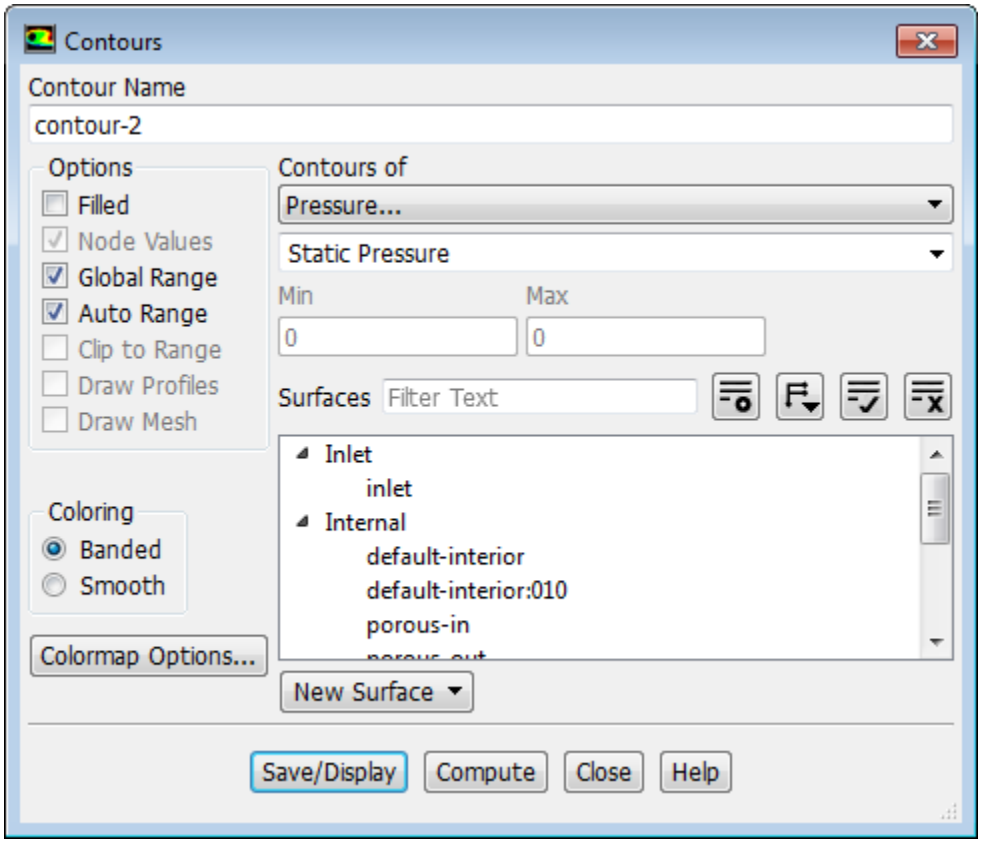
Build
builds the library and compiles the user-defined function.

Load
opens the specified library and loads the user-defined function.

38.2.12. Contours Dialog Box

The **Contours** dialog box controls the display of contour and profile plots. See Displaying Contours and Profiles (p. 1756) for details about the items below.

Postprocessing → Graphics → Contours → New...



Controls

Contour Name
is the name for a contour plot definition. You can specify a name or use the default name **`contour-id`**. This control appears only for contour plot definitions.

Options
contains the check buttons that set various contour display options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Filled
toggles between filled contours and line contours.

Node Values
toggles between using scalar field values at nodes and at cell centers for computing the contours. When the **Filled** option is off, **Node Values** is always on. See Choosing Node or Cell Values (p. 1761) for details.

Global Range
toggles between basing the minimum and maximum values on the range of values on the selected surfaces (off), and basing them on the range of values in the entire domain (on, the default).

Auto Range
toggles between automatic and manual setting of the contour range. Any time you change the **Contours of** selection, **Auto Range** is reset to on.

Clip to Range
determines whether or not values outside the prescribed **Min**/ **Max** range are contoured when using **Filled** contours. If selected, values outside the range will not be contoured. If not selected, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. See Specifying the Range of Magnitudes Displayed (p. 1759) for details.

Draw Profiles
causes the addition of a profile plot to the contour plot. The Profile Options Dialog Box (p. 2556) is opened when **Draw Profiles** is selected.

Draw Mesh
toggles between displaying and not displaying the mesh. The Mesh Display Dialog Box (p. 2163) is opened when **Draw Mesh** is selected.

Levels
sets the number of contour levels that are displayed.

Setup
indicates the ID number of the contour setup. For frequently used combinations of contour fields and options, you can store the information needed to generate the contour plot by specifying a **Setup** number and setting up the desired information in the **Contours** dialog box. See Storing Contour Plot Settings (p. 1762) for details.

Contours of
contains a list from which you can select the scalar field to be contoured.

Min
shows the minimum value of the scalar field. If **Auto Range** is off, you can set the minimum by typing a new value.

Max
shows the maximum value of the scalar field. If **Auto Range** is off, you can set the maximum by typing a new value.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surfaces
contains a list from which you can select the surfaces on which to draw contours. For 2D cases, if no surface is selected, contouring is done on the entire domain. For 3D cases, you must always select at least one surface.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

Display
draws the contours in the active graphics window.

Compute
calculates the scalar field and updates the **Min** and **Max** values (even when **Auto Range** is off).

Save/Display
plots the contour in the active graphics window and saves the contour plot definition. This button appears only for contour plot definitions and replaces the **Display** button.

38.2.13. Convergence Conditions Dialog Box

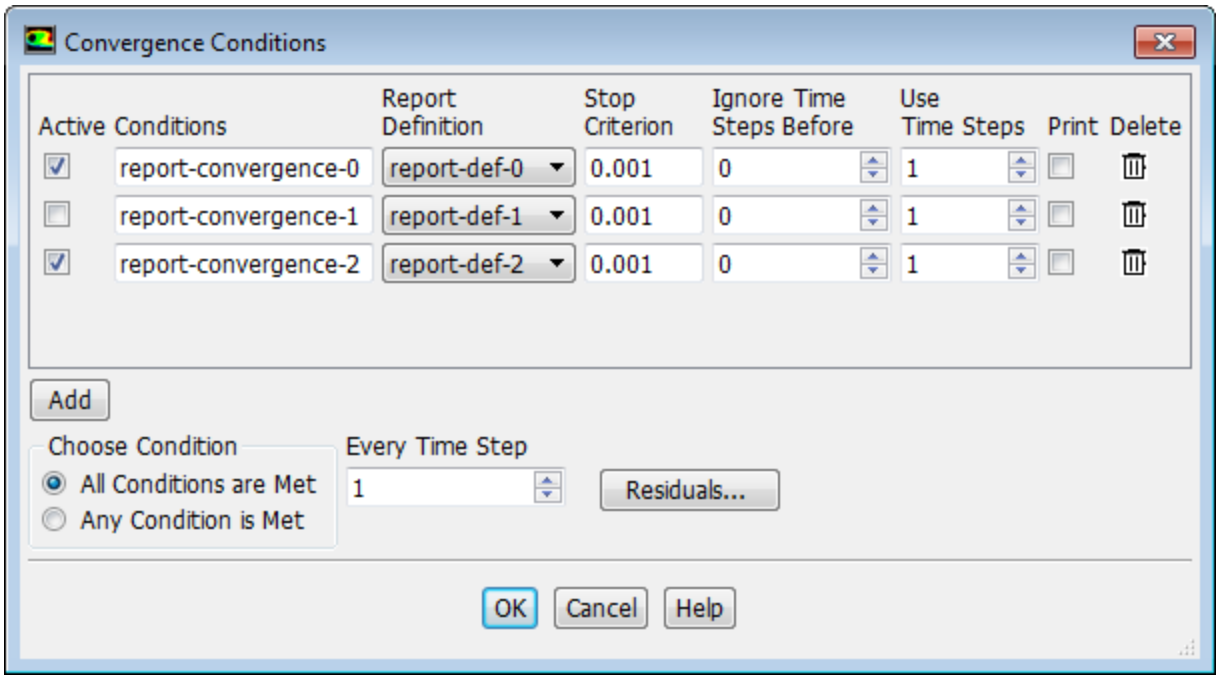
The convergence conditions facility allows you to set convergence conditions on the solution based on the values from report definitions (surface, volume, lift, drag, and so on). See Convergence Conditions (p. 1635) for details on setting up the **Convergence Conditions** dialog box.

Note

If you are solving a transient case, the **Convergence Conditions** dialog box will relabel some fields since the transient case uses time-steps rather than iterations. These alternate labels are indicated below.

Solving → Reports → Conditions...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Active
check box for deactivating/activating individual convergence conditions.

Conditions
name of the convergence condition.

Report Definition
name of the report definition used in judging convergence.

Stop Criterion
specifies the criterion below which the solution is considered to be converged.

Ignore Iterations Before | Ignore Time Steps Before
ignores the first few iterations/time-steps if you expect the solution to fluctuate initially.

Use Iterations | Use Time Steps
specifies the number of previous iterations/time-steps to be included in the report definition convergence check.

Choose Condition
to select the convergence conditions.

All Conditions are Met
The solution is considered to be converged if all of the convergence conditions' criteria are satisfied.

Any Condition is Met
The solution is considered to be converged if any of the convergence conditions' criteria is satisfied.

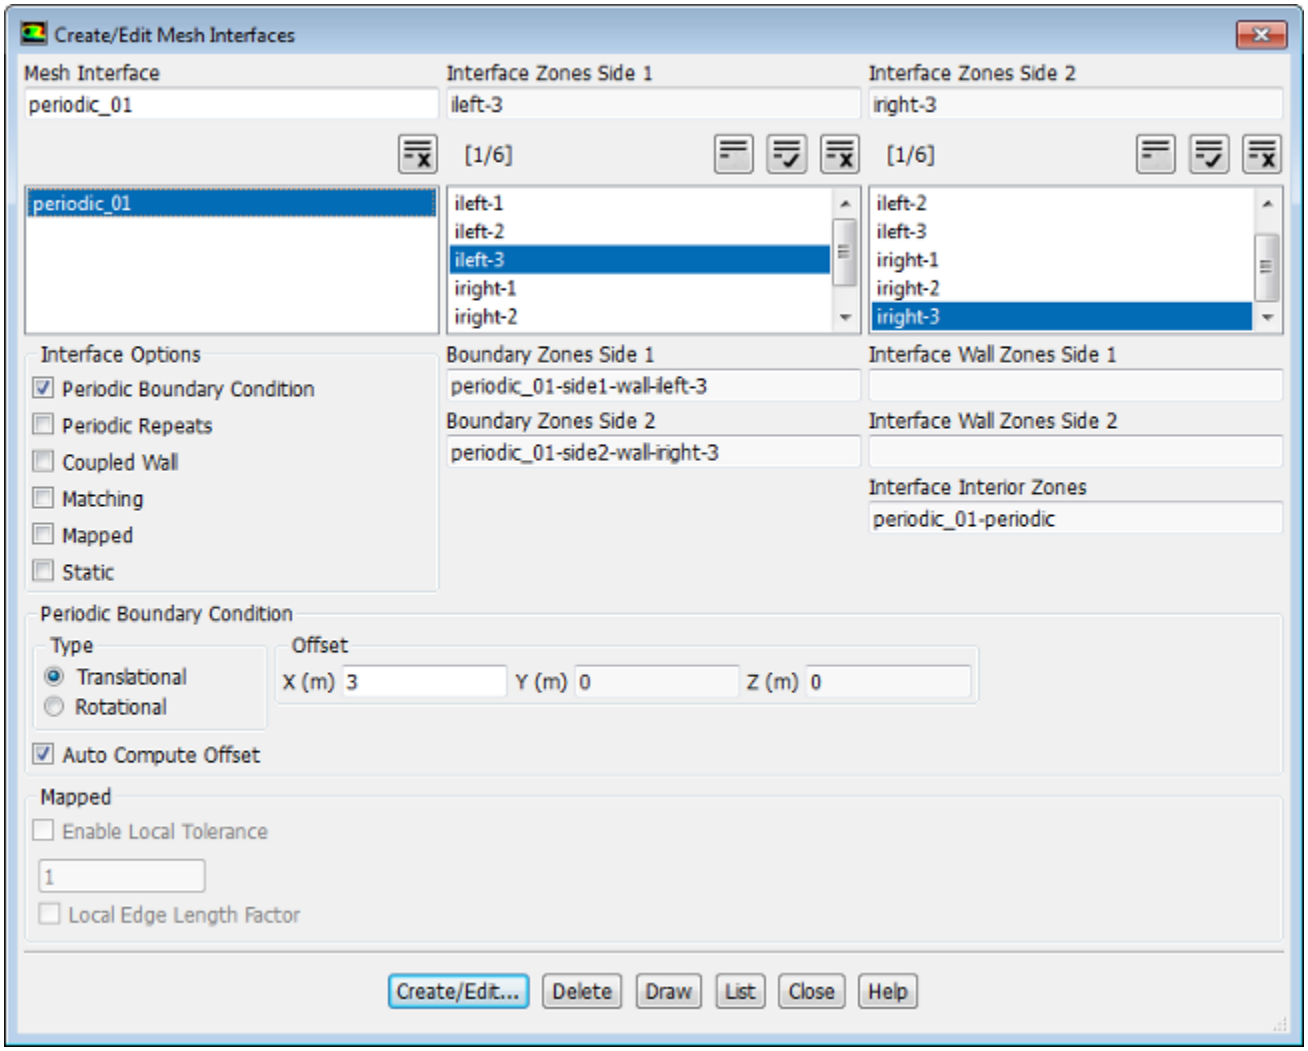
Every Iteration | Every Time-Step
to select how often convergence checks are done.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.14. Create/Edit Mesh Interfaces Dialog Box

The **Create/Edit Mesh Interfaces** dialog box allows you to manually create mesh interfaces for use with sliding meshes (see Using Sliding Meshes (p. 633)) or multiple reference frames (see Mesh Setup for a Multiple Moving Reference Frame (p. 616)), or for meshes with non-conformal boundaries (see Non-Conformal Meshes (p. 150)). This dialog box requires you to decide which interface zones make up both sides of each mesh interface. While it is possible to create every type of mesh interface using this dialog box, it is only necessary when you want your interface to use the periodic or periodic repeats option; for all other types it is more convenient to automatically create interfaces using the Mesh Interfaces Dialog Box (p. 2732), especially when you have many interface zones and/or are unfamiliar with their names / locations. For details, see Using a Non-Conformal Mesh in ANSYS Fluent (p. 164).

The **Create/Edit Mesh Interfaces** dialog box is opened by clicking the **Manual Create...** button in the Mesh Interfaces Dialog Box (p. 2732).



Controls

Mesh Interface

contains a text entry box in which you can set the name of the mesh interface, and a list from which you can select an existing mesh interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interface Zones Side 1, Interface Zones Side 2
contain selectable lists for the interface zones that comprise the mesh interface and informational fields that show the names of the zones you selected in each list. (You cannot edit the top fields; the names in these fields will be the names of the zones you selected in the list below it.)

Interface Options
contains options related to the interface type.

Periodic Boundary Condition
allows you to create a non-conformal periodic boundary condition interface.

Periodic Repeats
should be enabled when each of the two cell zones has a single pair of conformal or non-conformal periodics adjacent to the interface. This option is typically used in conjunction with the sliding mesh model, when simulating the interface between a rotor and stator; it allows ANSYS Fluent to treat the interface between the sliding and non-sliding zones as periodic where the two zones do not overlap. For details, see The Periodic Repeats Option (p. 154).

Coupled Wall
allows you to specify that the interface acts as a thermally coupled wall.

Matching
is relevant if only interface internal zones should be created (that is, interior or wall / shadow pairs), since the interface zones on both sides are aligned. With the **Matching** option, even interface zones that are not perfectly aligned are treated as if they are; however, if the discrepancy between the interface zones on both sides exceeds default thresholds, then warning messages will be displayed. Note that the **Matching** option is compatible with the **Periodic Boundary Condition**, **Coupled Wall**, and **Static** options. For more information about the recommended uses of this option, see Matching Option (p. 157).

Mapped

enables an alternative approach for modeling coupled walls between zones. This approach is more robust (but less accurate) than the standard non-conformal interface formulations when the interface zones penetrate each other or have gaps between them.

Note

The **Mapped** option is not compatible with shell conduction.

Static

reduces the memory usage and processing time (for interface creation and solution), especially when there are many zones on both sides of the interface. This option will only produce correct results if the interface zones do not move or deform relative to each other at the interface, and it is not compatible with the **Periodic Boundary Condition**, **Periodic Repeats**, or **Mapped** options.

Boundary Zones Side 1, Boundary Zones Side 2
display the names of any wall boundary zones created by ANSYS Fluent during the process of creating the selected mesh interface. If the two interface zones overlap each other completely, then the wall boundaries are created but with zero faces.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interface Wall Zones Side 1, Interface Wall Zones Side 2
display the names of any wall interface zones created by ANSYS Fluent during the process of creating the selected mesh interface.

Interface Interior Zones
displays the names of any interface interior zones created by ANSYS Fluent during the process of creating the selected mesh interface. This is used for embedded LES, when there is a need to be able to convert an interior zone into a RANS-LES interface.

Periodic Boundary Condition

Type
allows you to select a periodicity that is either **Translational** or **Rotational**.

Offset
is the offset coordinates or angle, depending on whether **Translational** or **Rotational** periodicity is selected. Note that when **Auto Compute Offset** is enabled, the **Offset** fields are not editable.

Auto Compute Offset
will result in ANSYS Fluent finding the offset. If this option is disabled, then you will have to provide the offset coordinates or angle in the required fields, depending on whether **Translational** or **Rotational** periodicity is selected.

Mapped

Enable Local Tolerance
(when enabled) allows you to overwrite any value specified in the **Mapped Tolerance** group box in the Interface Options Dialog Box (p. 2717), and is used on the selected interface only.

Local Edge Length Factor
(when enabled) allows you to specify the multiplier that Fluent uses with the smallest edge length of the interface zones to calculate the tolerance for mapping. Disabling **Local Edge Length Factor** allows you to specify an absolute value for the tolerance.

Create/Edit...
performs one of the following:

- If you have entered a new **Mesh Interface** name and selected unassigned zones from the **Interface Zones Side 1** and **Interface Zones Side 2** selection lists, a new mesh interface is created.
- If you have made a selection from the **Mesh Interface** list, the Edit Mesh Interfaces Dialog Box (p. 2696) will open so that you can revise the settings of existing mesh interfaces.

Delete
deletes the mesh interface selected under **Mesh Interface**.

Draw
allows you to display interface zones or mesh interfaces in the graphics window. Note that you can only select and display an interface zone from **Interface Zones Side 1** or **Interface Zones Side 2** if it is not yet assigned to an existing mesh interface. After a **Mesh Interface** is created, you can select the appropriate mesh interface and click the **Draw** button to display all of the zones under **Interface Zones Side 1** and **Interface Zones Side 2**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

List

prints information about the selected **Mesh Interface** in the console. When you click this button, ANSYS Fluent will list the two interface boundaries and (if you have initialized the solution) all new zones that were created (that is, wall and/or interior zones).

38.2.15. Custom Field Function Calculator Dialog Box

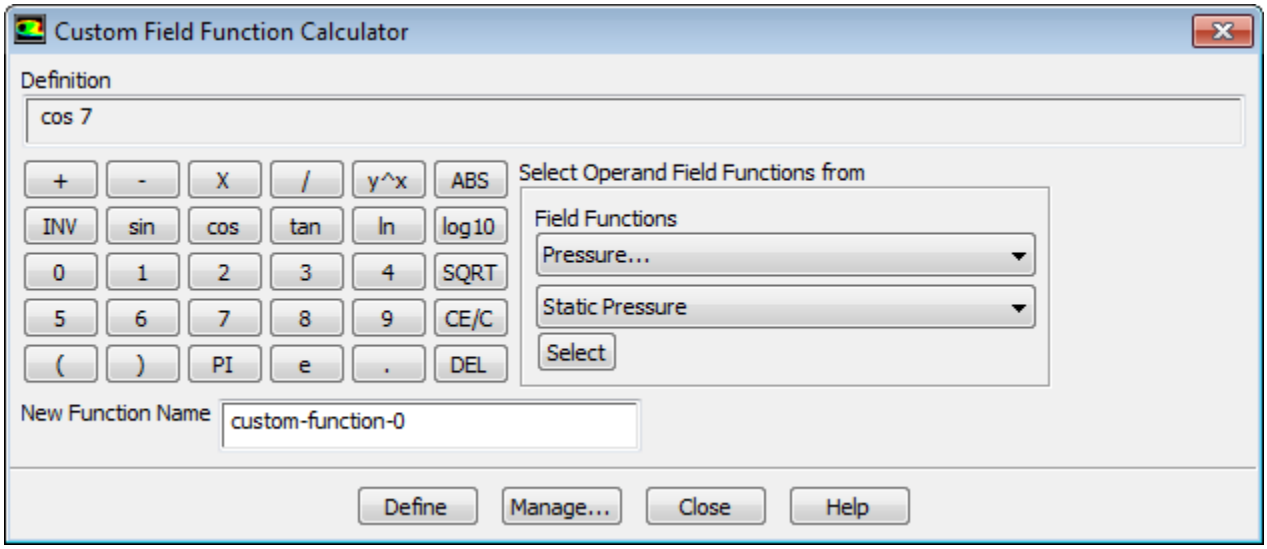
The **Custom Field Function Calculator** dialog box allows you to define custom field functions based on existing functions, using simple calculator operators. Any functions that you define will be added to the list of default flow variables and other field functions provided by ANSYS Fluent.

Important

Recall that you must enter all constants in the function definition in SI units.

See Creating a Custom Field Function (p. 2004) for details about the items below.

User Defined → Field Functions → Custom...



Controls

Definition

displays the function that you are currently defining. As you select each item from the **Field Functions** list or the calculator keypad, it will appear in the **Definition** text entry box. You *cannot* edit the contents of this box directly; if you want to delete part of a function, use the **Delete** button on the keypad.

(Calculator Buttons)

are buttons that perform calculator operations. When you select a calculator button (by clicking on it), the appropriate symbol will appear in the **Definition** text entry box.

Select Operand Field Functions from

contains the available field functions and the means for selecting them.

Field Functions

contains a list from which you can select a variable to be used in the definition of a new function.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select
enters the variable that is currently selected in the **Field Functions** list in the **Definition** field.

New Function Name
specifies the name of the function you are defining. Should you decide to change the function name after you have defined the function, you can do so in the Field Function Definitions Dialog Box (p. 2704), which you can open by clicking on the **Manage...** button.

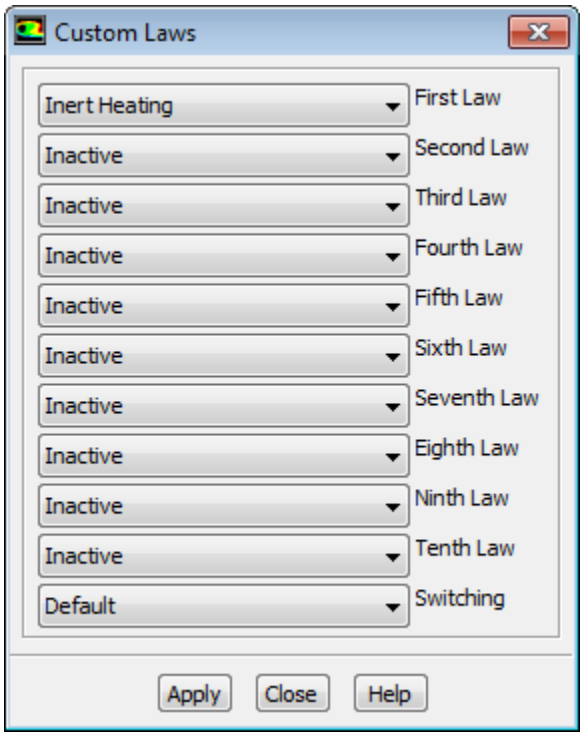
Define
creates the function and adds it to the list of **Custom Field Functions** within the drop-down list of available field functions. The **Define** button is grayed out after you create a new function or if the **Definition** field is empty.

Manage...
opens the Field Function Definitions Dialog Box (p. 2704), which enables you to check, rename, save, load, and delete custom field functions.

38.2.16. Custom Laws Dialog Box

The **Custom Laws** dialog box is used to incorporate user-defined functions (see the separate Fluent Customization Manual for details) in place of the default physical laws (1 through 6) used in the heat/mass transfer calculations.

The **Custom Laws** dialog box is opened from the Set Injection Properties Dialog Box (p. 2796).



Controls

First Law, Second Law, Third Law, Fourth Law, Fifth Law, Sixth Law
contain drop-down lists in which you can choose a user-defined particle law to replace the standard law.

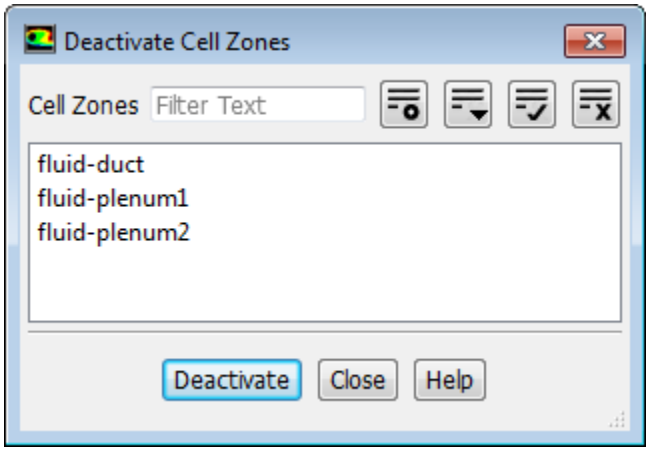
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Switching
contains a drop-down list in which you can select a user-defined function that customizes the way ANSYS Fluent switches between particle laws.

38.2.17. Deactivate Cell Zones Dialog Box

The **Deactivate Cell Zones** dialog box allows you to deactivate a single cell zone or multiple zones. See Deactivating Zones (p. 220) for details.

Setting Up Domain → Zones → Deactivate...



Controls

Cell Zones
contains a list of cell zones from which you can select the zone to be deactivated.

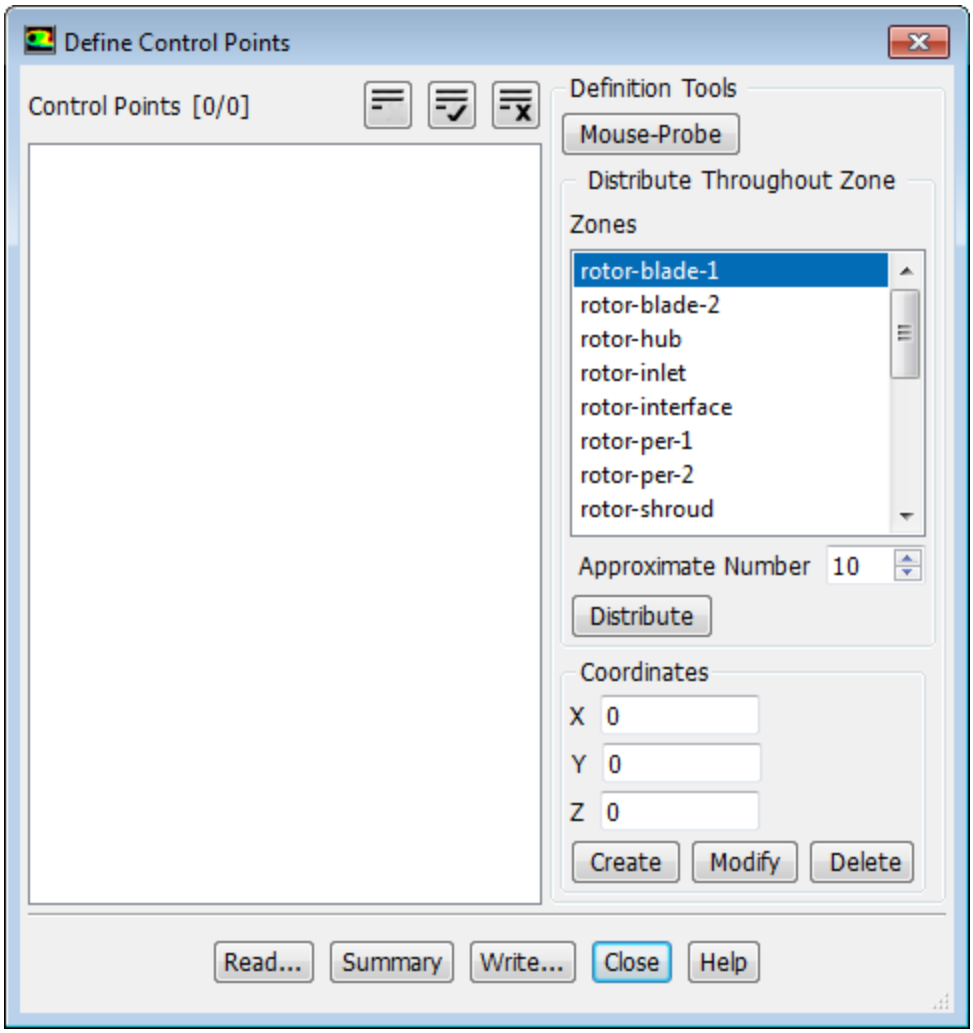
Deactivate
deactivates the selected cell zones.

38.2.18. Define Control Points Dialog Box

The **Define Control Points** dialog box allows you to create, modify, and delete control points for the mesh morpher/optimizer when the unstructured control point distribution is selected. See Using the Mesh Morpher/Optimizer (p. 2125) for details about using this dialog box.

The **Define Control Points** dialog box is opened from the Mesh Morpher/Optimizer Dialog Box (p. 2734).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Control Points
lists the control points you have created and allows you to modify and delete them.

Definition Tools
provides tools for defining the control points.

Mouse-Probe
allows you to create control points by probing (using the right mouse button, by default) in the graphics window.

Distribute Throughout Zone
allows you to quickly create a number of control points and distribute them on mesh nodes throughout a specific boundary zone.

Zones
allows you to select the boundary zone throughout which you want to distribute control points.

Approximate Number
allows you to specify the approximate number of control points you want to distribute throughout a zone. Note that due to the method by which the control points are distributed, the actual number may exceed the value you enter.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distribute
creates a number of control points on mesh nodes throughout the specified zone (within the bounding box) with a distribution that is based on the distribution of the cell faces in that zone.

Coordinates
allows you to view and modify the coordinates of control points, as well as to create new control points and to delete existing control points.

X, Y, Z
displays the coordinates of the selected **Control Point**, and allows you to define new ones and edit existing ones.

Create
creates a new control point at the currently displayed **X**, **Y**, and **Z** coordinates.

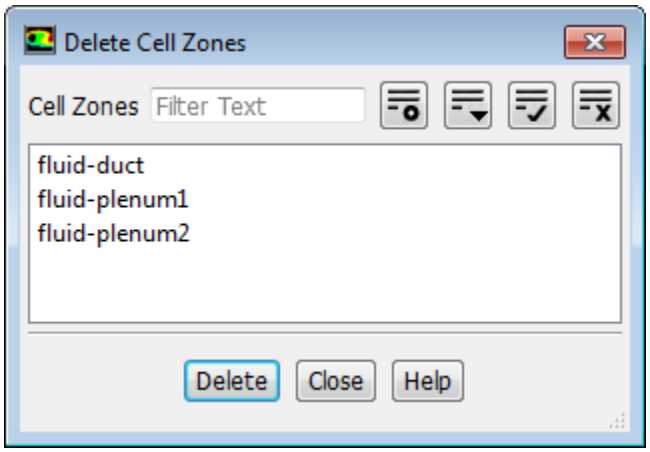
Modify
revises the **X**, **Y**, and **Z** coordinates of the selected **Control Point**.

Delete
deletes the selected **Control Point**.

38.2.19. Delete Cell Zones Dialog Box

The **Delete Cell Zones** dialog box allows you to delete a single cell zone or multiple zones. See Deleting Zones (p. 219) for details.

Setting Up Domain → Zones → Delete...



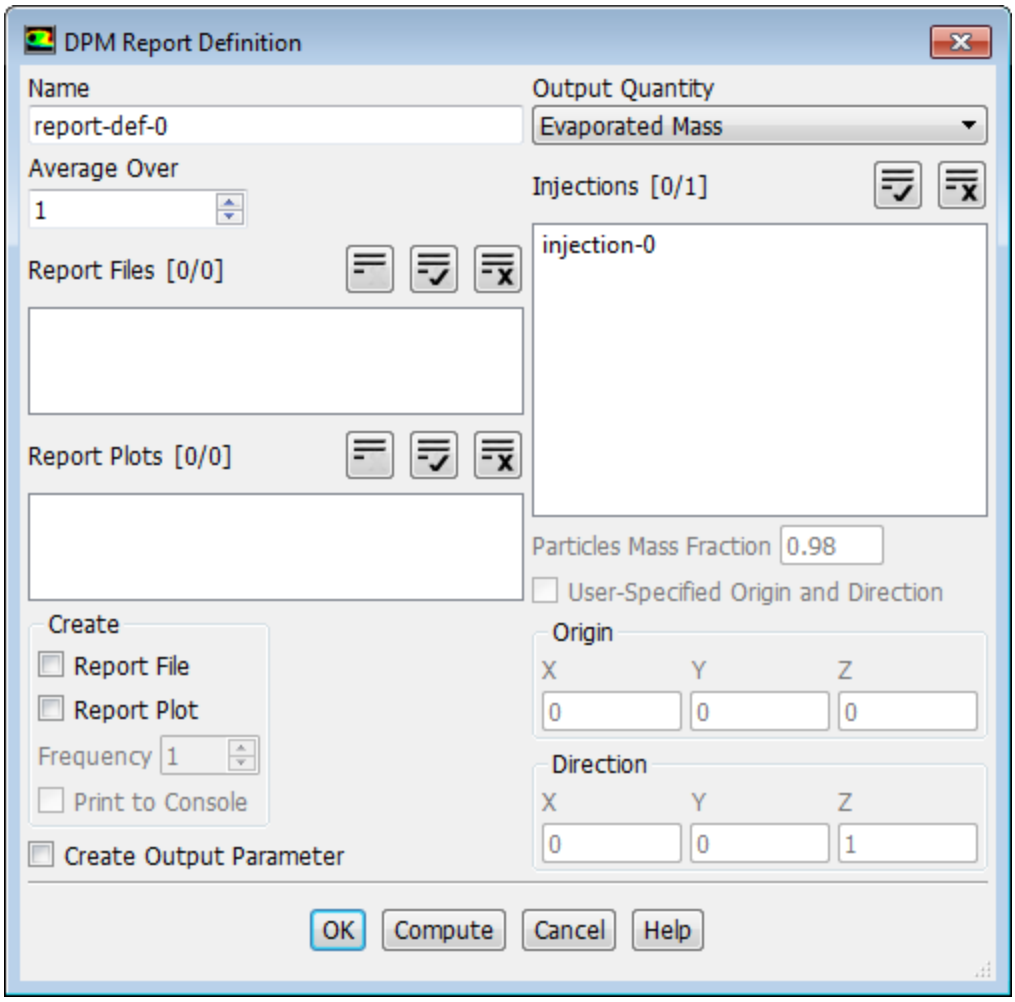
Controls

Cell Zones
contains a list of cell zones from which you can select the zone to be deleted.

Delete
deletes the selected cell zones.

38.2.20. DPM Report Definition Dialog Box

Solving → Reports → Definitions → New → DPM Report



Controls

Average Over

(optional) To have Fluent calculate a running average for the **DPM Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Report Files

lists all of the report files where you can write the report definition data.

Report Plots

lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File

creates a new report file that includes this report definition.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Output Quantity

Injected Mass
(unsteady particle tracking only) total mass injected into the domain.

Mass in Domain
(unsteady particle tracking only) total mass present in the domain.

Escaped Mass
reports the mass that has left the domain through a certain boundary or boundaries.

Evaporated Mass
reports the total evaporated mass for the selected injection(s). The quantity accounts for fully evaporated particles as well as all mass that has evaporated from any other particles. For unsteady tracking, this includes particles that are still present in the domain.

Penetration Length
(unsteady particle tracking only) reports the total penetration length in meters.

Injections
lists the injections that you can select for discrete phase reporting. For the **Escaped Mass** output quantity, this item is available only if you have enabled the `report/dpm-zone-summaries-per-injection` text command. Note that for unsteady particle tracking, if you want to report the mass of escaped particles per injection, this text command must be enabled before any particles are injected into the domain.

Boundaries
contains a selectable list of valid boundary zones for escaped mass reporting.

Show Mass Flow/Change Rate
(unsteady particle tracking only) if enabled, specifies that the mass flow rate will be reported (default). Otherwise the total mass will be reported. This item is not available for the **Penetration Length** report.

Particles Mass Fraction
the mass fraction expected between the injection nozzle and the penetration length. This item is available only for the **Penetration Length** reports.

User-Specified Origin and Direction
once enabled, it allows you to specify the **Origin** and **Direction** of the selected injection(s). This item is available only for the **Penetration Length** reports.

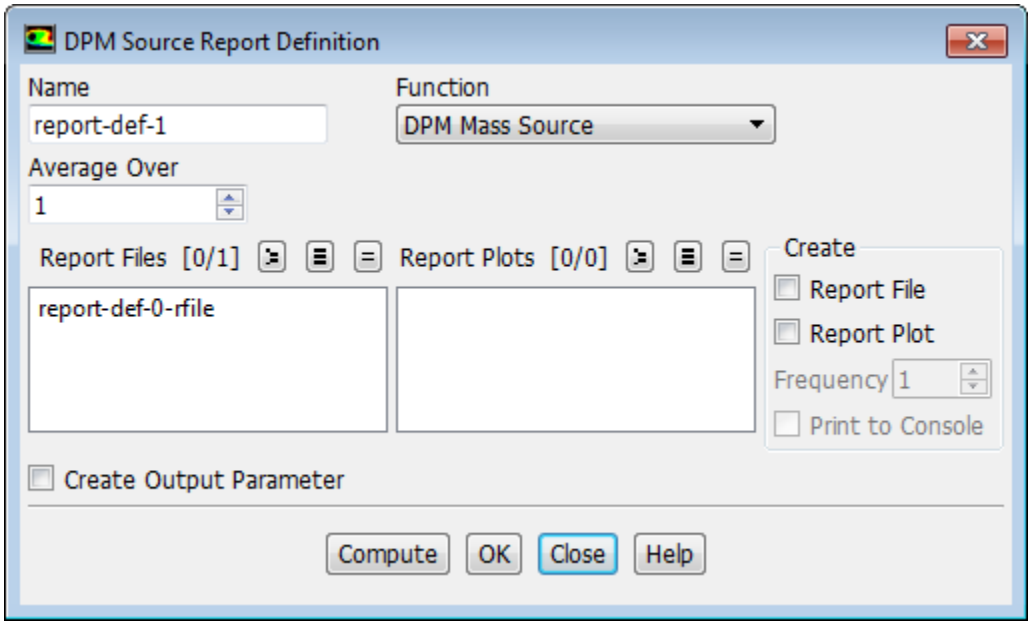
OK
creates the report definition.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Compute
computes the value of the report definition and prints to the console.

38.2.21. DPM Source Report Definition

Solving → Reports → Definitions → New → Flux Report → DPM Mass Source | DPM Enthalpy Source | DPM Sensible Enthapy Source



Controls

Function

DPM Mass Source
reports the mass contributions from the particle injections.

DPM Enthalpy Source
reports the heat contributions from the particle injections.

DPM Sensible Enthalpy Source
reports the sensible heat contributions from the particle injections.

Average Over
(optional) To have Fluent calculate a running average for the **DPM Source Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Report Files
lists all of the report files where you can write the report definition data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

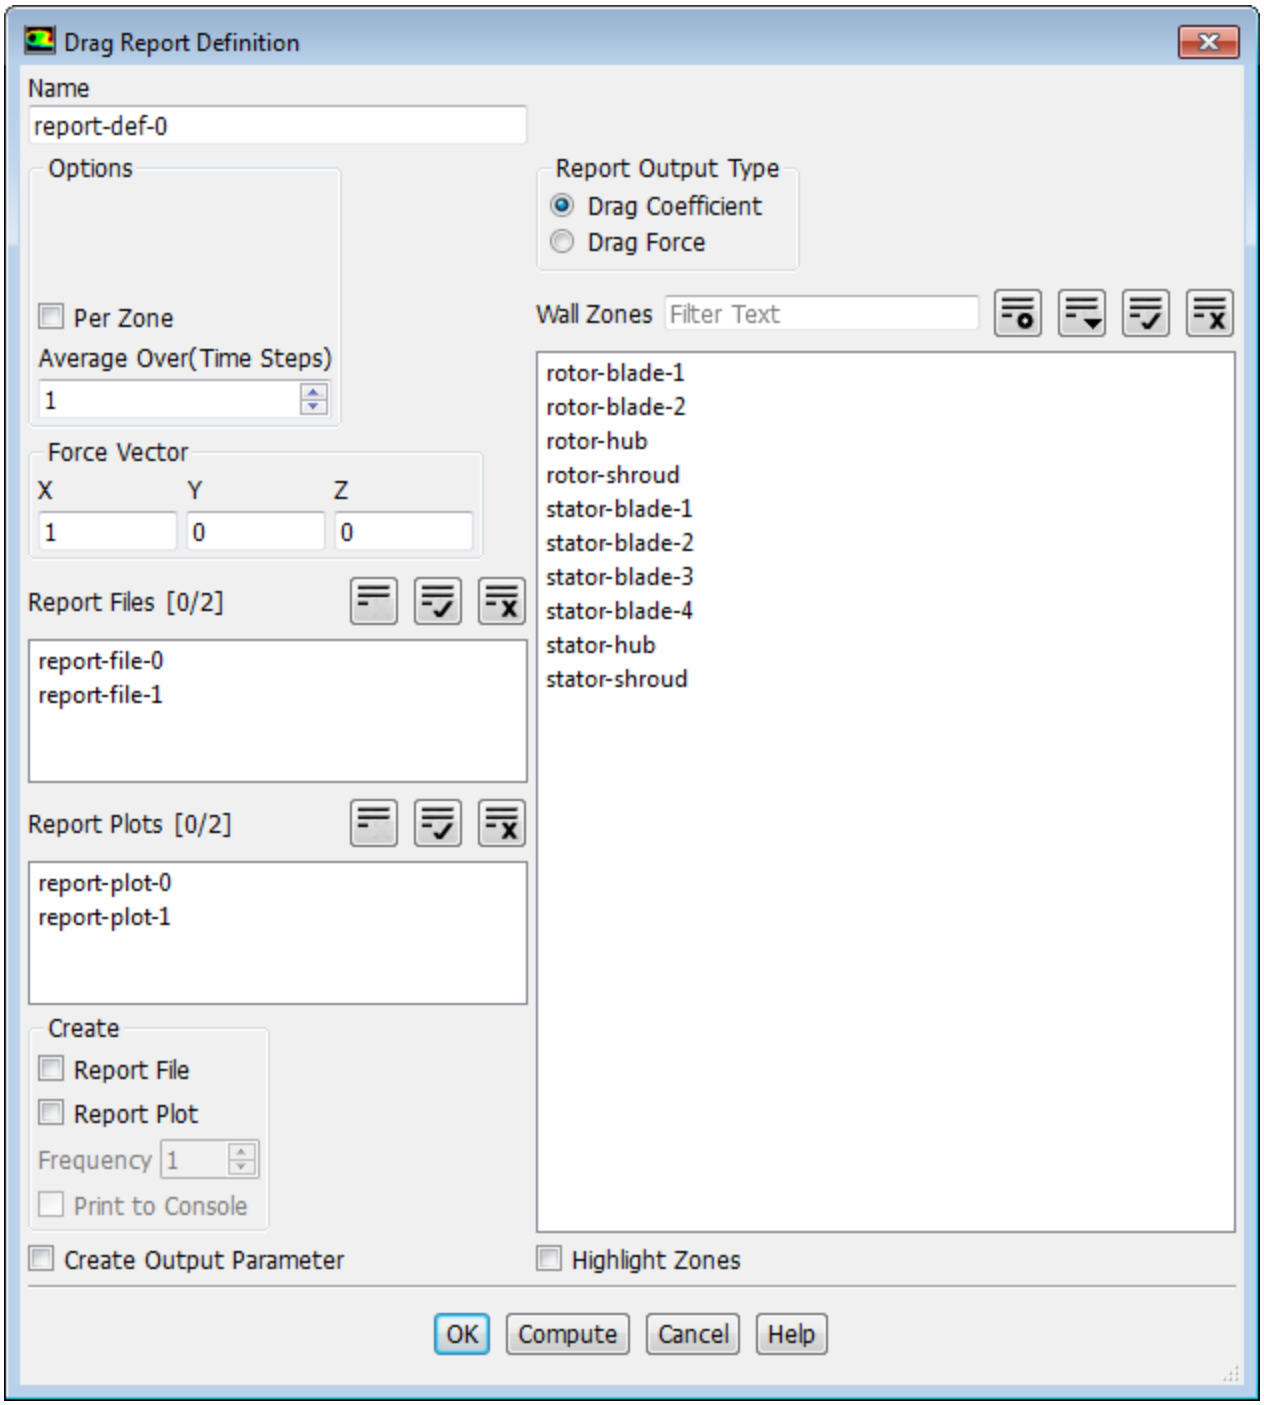
Compute
computes the value of the report definition and prints to the console.

OK
creates the report definition.

38.2.22. Drag Report Definition Dialog Box

Solving → Reports → Definitions → New → Force Report → Drag...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Per Zone
specifies whether or not the drag for multiple walls zones should be monitored on each wall zone separately.When this option is turned off (the default), Fluent computes and monitors the total drag for all of the selected walls zones combined together.

Average Over (Time-Steps), Average Over (Iterations)
(optional) To have Fluent calculate a running average for the **Drag Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Force Vector
contains the components of the force vector.

X,Y,Z
are the components of the force vector along which the forces will be computed.

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Report Output Type

Drag Coefficient
specifies the report definition as a unitless quantity.

Drag Force
specifies that the report definition has units of force.

Wall Zones
lists the zones you can select for drag coefficient or drag force computation.

OK
creates the report definition.

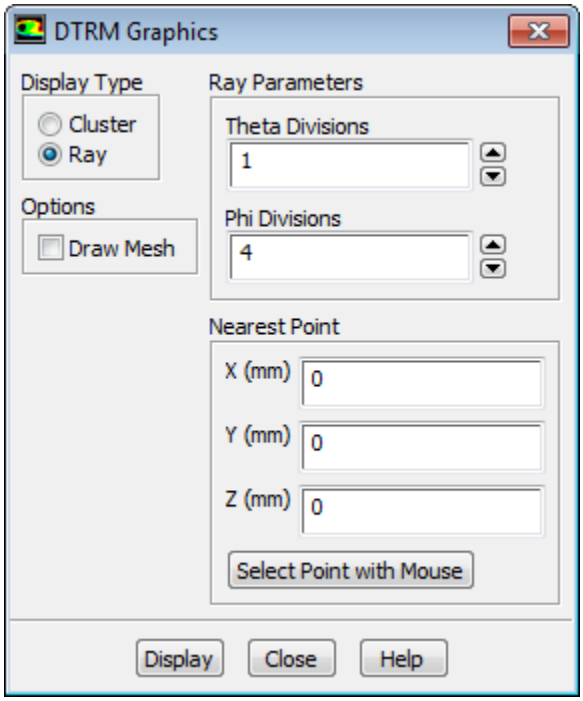
Compute
computes the value of the report definition at the selected zone(s) and prints to the console.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.23. DTRM Graphics Dialog Box

The **DTRM Graphics** dialog box allows you to display rays and clusters used by the DTRM. See Displaying Rays and Clusters for the DTRM (p. 883) for details.

Postprocessing → Model Specific → DTRM Graphics...



Controls

Display Type
contains options for the different items you can display.

Cluster
specifies the display of clusters.

Ray
specifies the display of rays.

Options
contains check buttons that control display options.

Draw Mesh
toggles between displaying and not displaying the mesh. The Mesh Display Dialog Box (p. 2163) is opened when **Draw Mesh** is selected.

Cluster Type
specifies whether **Surface** clusters or **Volume** clusters are to be displayed. This section of the dialog box appears when **Cluster** is selected as the **Display Type**.

Cluster Selection
contains options for cluster displays. This section of the dialog box appears when **Cluster** is selected as the **Display Type**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Display All Clusters
enables the display of all surface or volume clusters in the domain.

Ray Parameters
contains controls for displaying rays. This section of the dialog box appears when **Ray** is selected as the **Display Type**.

Theta Divisions, Phi Divisions
control the number of rays being traced. (See Controlling the Rays (p. 850).)

Nearest Point
specifies a point (**X,Y,Z**) near the cluster to be displayed (or the cluster from which the rays should start).

The **Nearest Point** controls are not available when **Display All Clusters** is selected under **Cluster Selection**.

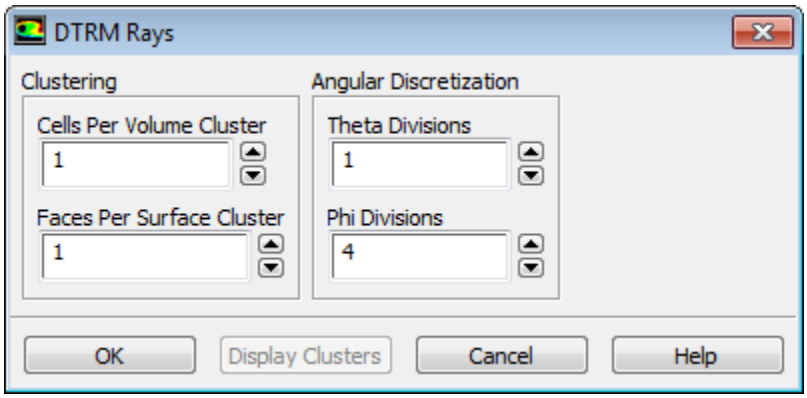
Select Point With Mouse
is an alternative method for specifying the **Nearest Point** using your mouse, by clicking the button.

Display
displays the specified cluster(s) or rays.

38.2.24. DTRM Rays Dialog Box

The **DTRM Rays** dialog box allows you to define the rays used by the discrete transfer radiation model (DTRM). It opens automatically when you click **OK** after selecting the **Discrete Transfer** model in the Radiation Model Dialog Box (p. 2190). See Setting Up the DTRM (p. 848) for details about the items below.

Setting Up Physics → Model Specific → DTRM Rays...



Controls

Clustering
contains parameters for the clusters (see Clustering in the Theory Guide).

Cells Per Volume Cluster, Faces Per Surface Cluster
control the number of radiating surfaces and absorbing cells. (See the explanation in Controlling the Clusters (p. 849).)

Angular Discretization
contains parameters for the ray traces (see Ray Tracing in the Theory Guide).

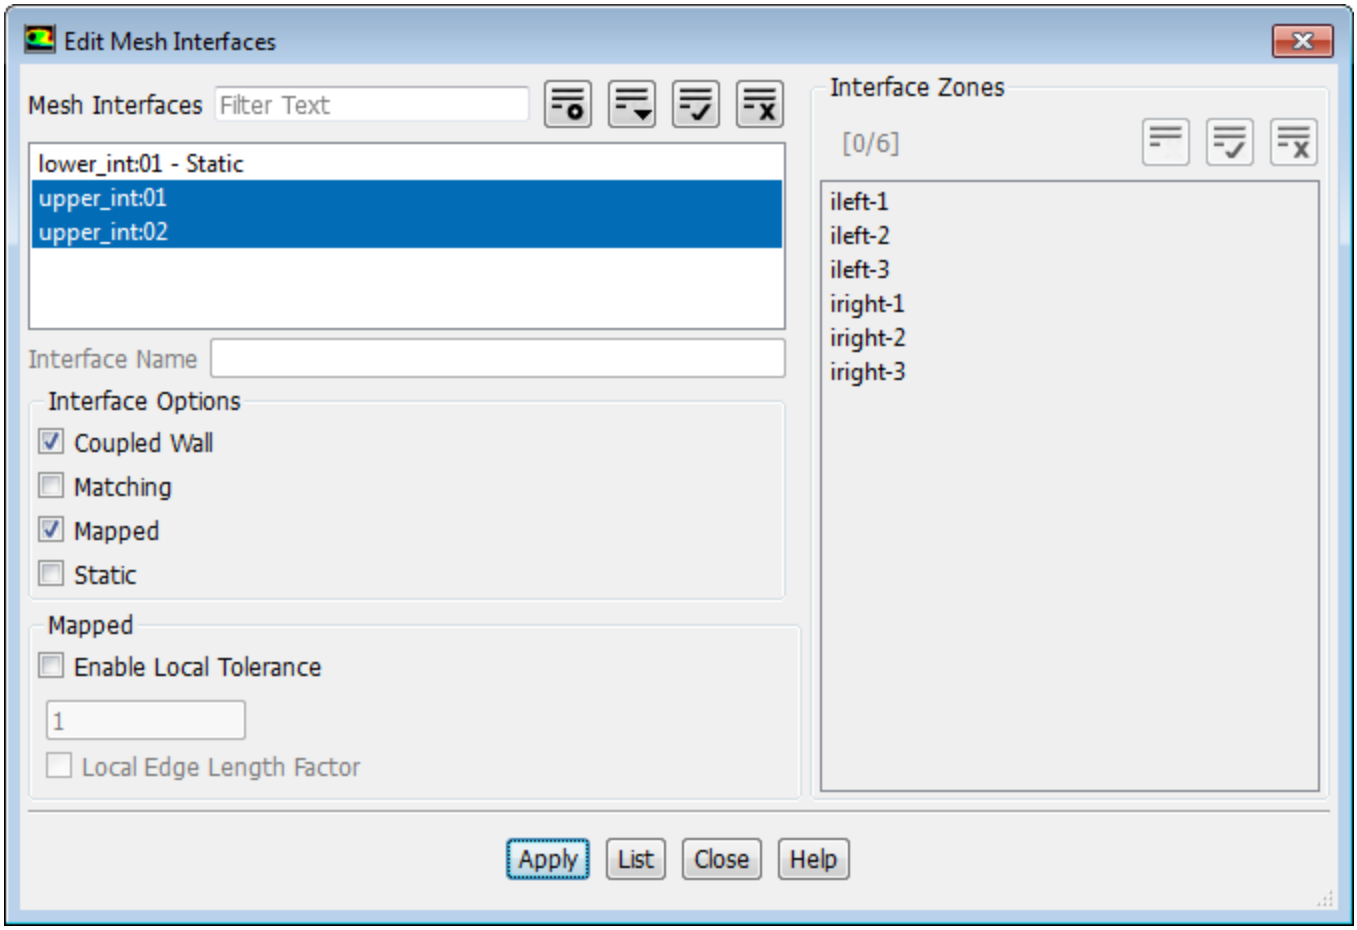
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Theta Divisions, Phi Divisions
control the number of rays being traced. (Guidelines are provided in Controlling the Rays (p. 850).)

Display Clusters
generates a graphical display of the clusters in the domain. (This item is available only after you have created or read a ray file.)

38.2.25. Edit Mesh Interfaces Dialog Box

The **Edit Mesh Interfaces** dialog box allows you to edit existing mesh interfaces (see Using a Non-Conformal Mesh in ANSYS Fluent (p. 164)). It is opened by making a selection from the **Mesh Interfaces** list in the Mesh Interfaces Dialog Box (p. 2732) and clicking **Edit...**.



Controls

Mesh Interfaces

allows you to select the mesh interfaces you would like to edit. Note that you can click the button to group the interfaces in the list by their currently enabled interface option(s), which allows you to select / deselect all those of a particular type by simply clicking the top-level branch.

Interface Name
edits the name of the mesh interface. This is only available when a single interface is selected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interface Options

contains options related to the interface type. These options can be applied when a single or multiple interfaces are selected.

Periodic Boundary Condition

allows you to create a non-conformal periodic boundary condition interface.

Periodic Repeats

should be enabled when each of the two cell zones has a single pair of conformal or non-conformal periodics adjacent to the interface. This option is typically used in conjunction with the sliding mesh model, when simulating the interface between a rotor and stator; it allows ANSYS Fluent to treat the interface between the sliding and non-sliding zones as periodic where the two zones do not overlap. For details, see The Periodic Repeats Option (p. 154).

Coupled Wall

allows you to specify that the interface acts as a thermally coupled wall.

Matching

is relevant if only interface internal zones should be created (that is, interior or wall / shadow pairs), since the interface zones on both sides are aligned. With the **Matching** option, even interface zones that are not perfectly aligned are treated as if they are; however, if the discrepancy between the interface zones on both sides exceeds default thresholds, then warning messages will be displayed. Note that the **Matching** option is compatible with the **Periodic Boundary Condition**, **Coupled Wall**, and **Static** options. For more information about the recommended uses of this option, see Matching Option (p. 157).

Mapped

enables an alternative approach for modeling coupled walls between zones. This approach is more robust (but less accurate) than the standard non-conformal interface formulations when the interface zones penetrate each other or have gaps between them.

Note

The **Mapped** option is not compatible with shell conduction.

Static

reduces the memory usage and processing time (for interface creation and solution), especially when there are many zones on both sides of the interface. This option will only produce correct results if the interface zones do not move or deform relative to each other at the interface, and it is not compatible with the **Periodic Boundary Condition**, **Periodic Repeats**, or **Mapped** options.

Periodic Boundary Conditions

Type

allows you to select a periodicity that is either **Translational** or **Rotational**.

Offset

is the offset coordinates or angle, depending on whether **Translational** or **Rotational** periodicity is selected. Note that when **Auto Compute Offset** is enabled, the **Offset** fields are not editable.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Auto Compute Offset
will result in ANSYS Fluent finding the offset. If this option is disabled, then you will have to provide the offset coordinates or angle in the required fields, depending on whether **Translational** or **Rotational** periodicity is selected.

Mapped

Enable Local Tolerance
(when enabled) allows you to overwrite any value specified in the **Mapped Tolerance** group box in the Interface Options Dialog Box (p. 2717), and is applied to the selected interface only.

Local Edge Length Factor
(when enabled) allows you to specify the multiplier that Fluent uses with the smallest edge length of the interface zones to calculate the tolerance for mapping. Disabling **Local Edge Length Factor** allows you to specify an absolute value for the tolerance.

Interface Zones
highlights the list of interface zones that comprise the selected mesh interface and allows you to edit the list (provided that the zones you select are unassigned and located appropriately). This functionality is only available when a single interface is selected.

List
prints information in the console about the first mesh interface you selected. When you click this button, ANSYS Fluent will list the two interface boundaries and (if you have initialized the solution) all new zones that were created (that is, wall and/or interior zones).

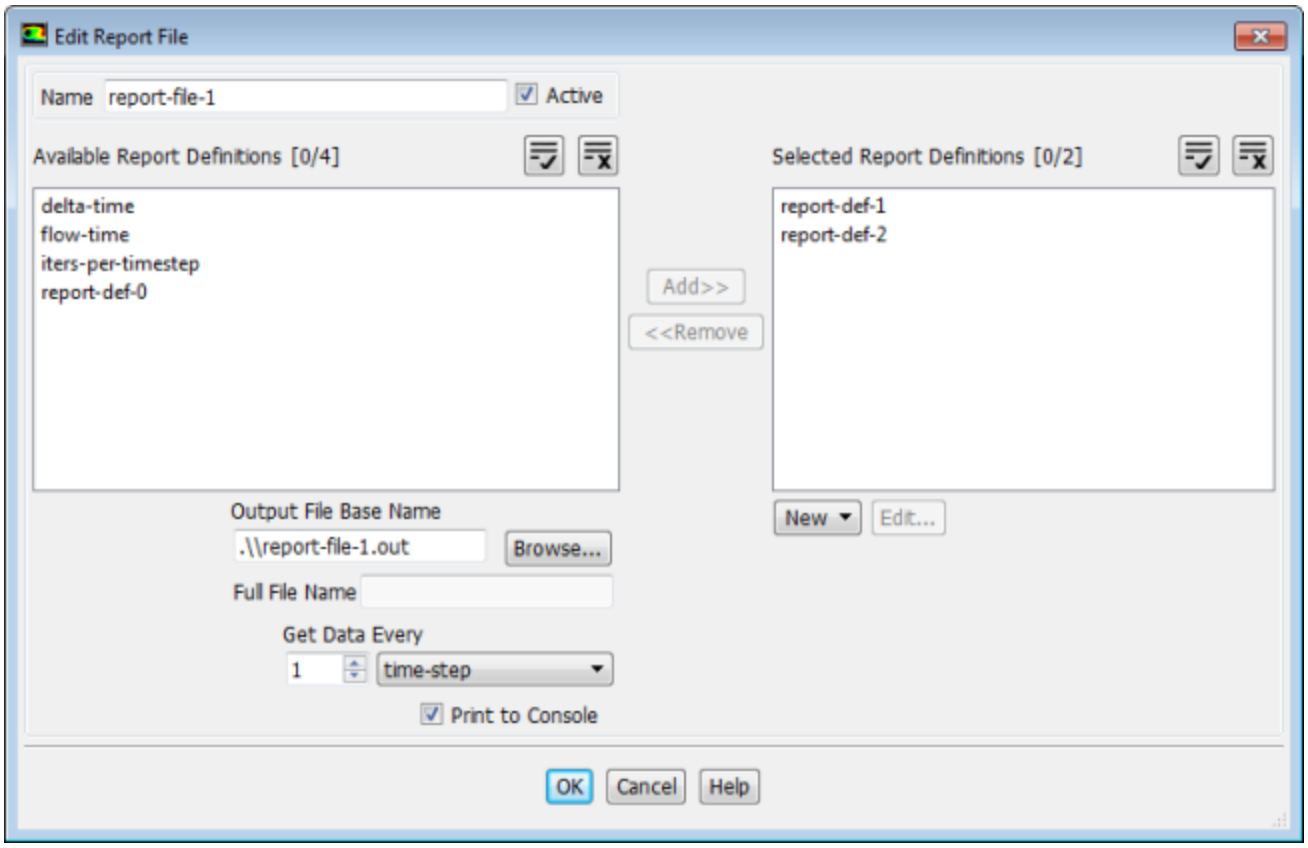
Apply
saves the revised settings for the selected mesh interfaces.

38.2.26. Edit Report File Dialog Box

Solving → **Reports** → **File...**

Select a report file in the **Report File Definition** dialog box and click **Edit...** to open the **Edit Report File** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
editable field displaying the name of the report file.

Active
check box (enabled by default) that determines if the file is written during the solution calculation.

Available Report Definitions
lists all of the existing report definitions not currently part of this report file.

Add>>
moves the selected report definition(s) to the **Selected Report Definitions** list.

<<Remove
moves the selected report definition(s) to the **Available Report Definitions** list.

Output File Base Name
allows you to specify the name used when the file is saved.

Browse...
opens the **Select File** dialog box, allowing you to specify the location where the report file will be saved.

Full File Name
displays the name and location of the report file once it has been saved.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Get Data Every
indicates the frequency that the report definition data is written to the file. The default value of 1 allows you to write to the file at every iteration or time-step. Time-step is only a valid choice you are calculating unsteady flow.

Print to Console
indicates whether or not the contents of the report file are printed to the console at the frequency specified in the **Get Data Every** field.

Selected Report Definitions
lists all of the existing report definitions currently included in this report file.

New
drop-down list allowing you to create new report definitions (surface, volume, force, flux, dpm, and user-defined).

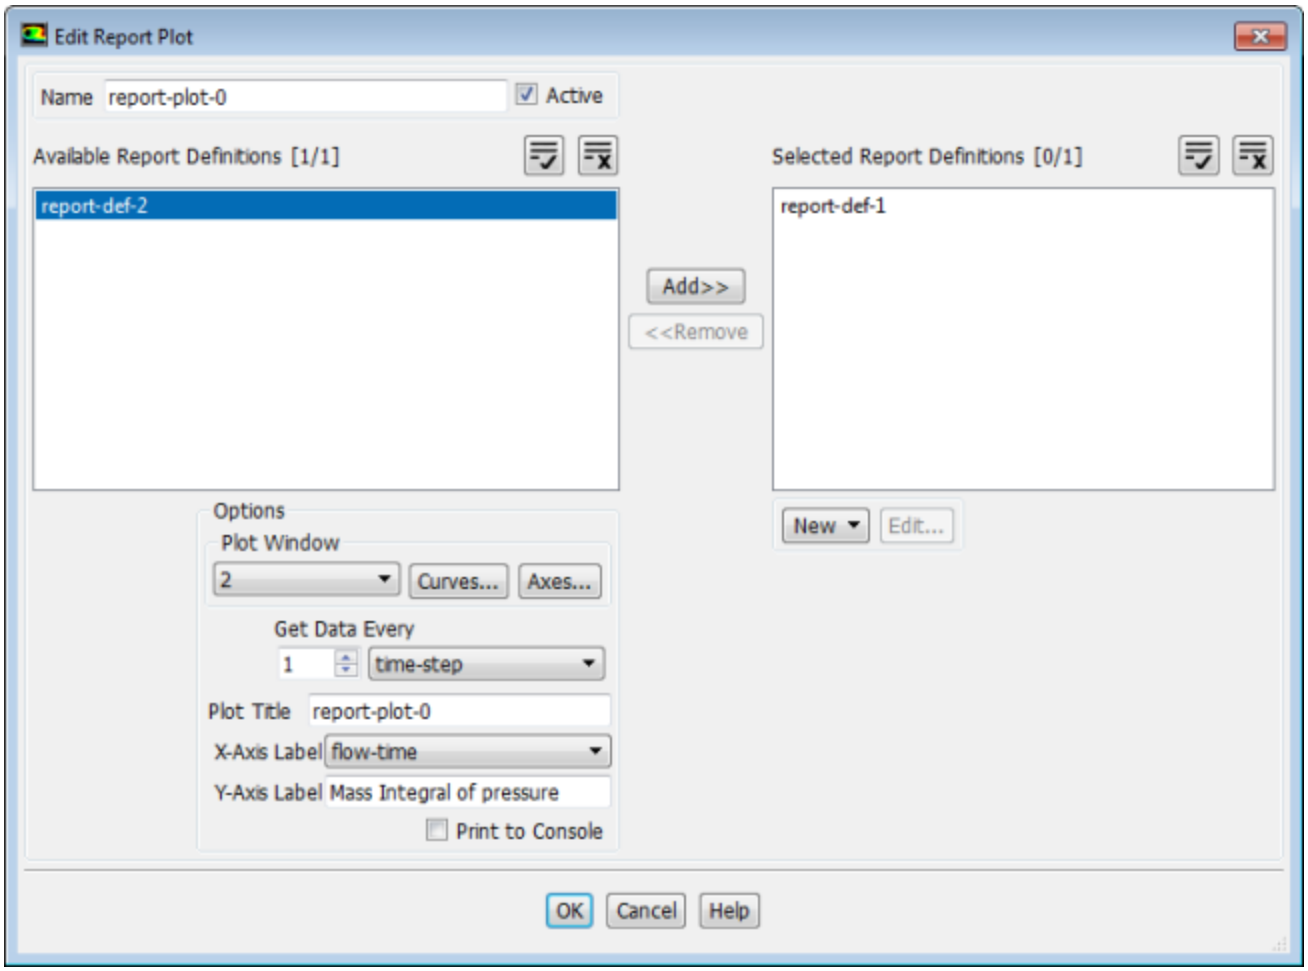
Edit...
allows you to modify the highlighted report definition in the **Selected Report Definition** list.

38.2.27. Edit Report Plot Dialog Box

Solving → **Reports** → **Plot...**

Select a report plot in the **Report Plot Definition** dialog box and click **Edit...** to open the **Edit Report Plot** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
editable field displaying the name of the report plot.

Active
check box (enabled by default) that determines if the plot is plotted during the solution calculation.

Available Report Definitions
lists all of the existing report definitions not currently part of this report plot.

Add>>
moves the selected report definition(s) to the **Selected Report Definitions** list.

<<Remove
moves the selected report definition(s) to the **Available Report Definitions** list.

Options

Plot Window
allows you to specify the graphics window for this report plot.

Curves...
opens the Curves Dialog Box (p. 2610).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axes...
opens the Axes Dialog Box (p. 2608).

Get Data Every
indicates the frequency that the report definition data is plotted in the graphics window. The default value of 1 allows you to plot the data at every iteration or time-step. Time-step is only a valid choice you are calculating unsteady flow.

Plot Title
provide a title for the plot.

X-Axis Label
choose whether the X-axis is flow-time or time-step.

Y-Axis Label
enter a label for the Y-axis.

Print to Console
indicates whether or not the contents of the report plot are printed to the console at the frequency specified in the **Get Data Every** field.

Selected Report Definitions
lists all of the existing report definitions currently included in this report plot.

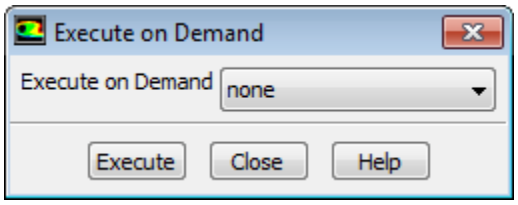
New
drop-down list allowing you to create new report definitions (surface, volume, force, flux, dpm, and user-defined).

Edit...
allows you to modify the highlighted report definition in the **Selected Report Definition** list.

38.2.28. Execute on Demand Dialog Box

The **Execute on Demand** dialog box allows you to run a specified user-defined function immediately. See the separate Fluent Customization Manual for details.

User Defined → User Defined → Execute on Demand...



Controls

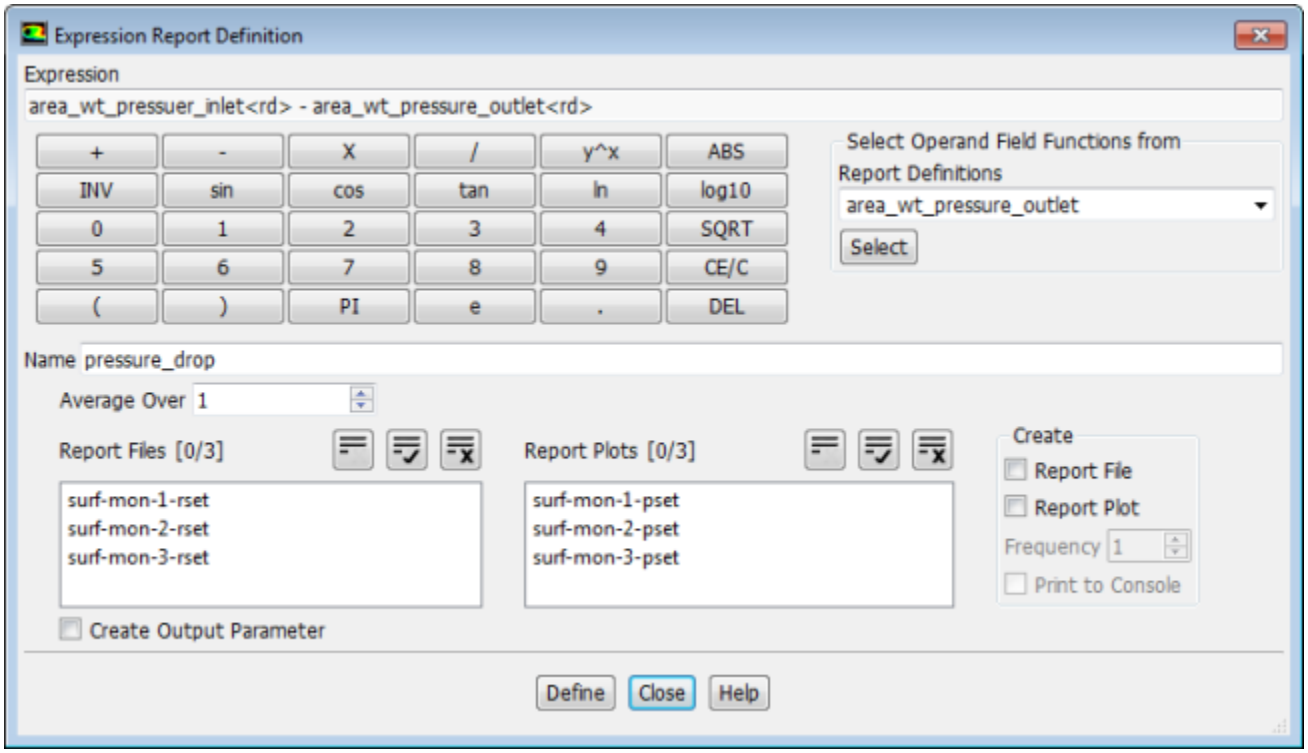
Execute on Demand
selects the user-defined function to be run.

Execute
runs the selected function.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.29. Expression Report Definition Dialog Box

Solving → Reports → Definitions → New → Expression



Controls

Expression
displays the formula of the expression as you create it.

Select Operand Field Functions from

Report Definitions
drop-down list containing all of the currently-defined report definitions.

Select
adds the listed report definition to the **Expression** formula.

Average Over
(optional) To have Fluent calculate a running average for the **Expression Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Report Files
lists all of the report files where you can write the report definition data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

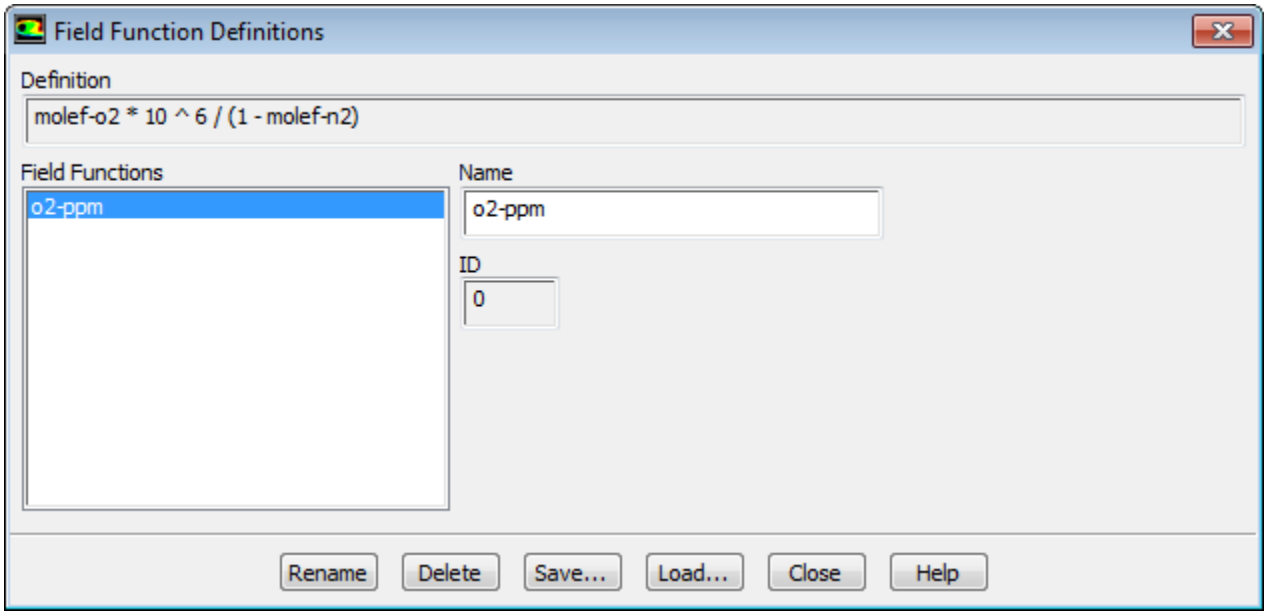
Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Define
creates the report definition.

38.2.30. Field Function Definitions Dialog Box

The **Field Function Definitions** dialog box allows you to check, rename, save, load, and delete custom field functions that you defined in the Custom Field Function Calculator Dialog Box (p. 2683). See Manipulating, Saving, and Loading Custom Field Functions (p. 2006) for details about the items below.

The **Field Function Definitions** dialog box is opened from the Custom Field Function Calculator Dialog Box (p. 2683).



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Definition
displays the function selected in the **Field Functions** list. This display is for informational purposes only; you cannot edit it.

Field Functions
contains a selectable list of custom field functions. When you select a function, its definition will appear in the **Definition** box and its name will appear in the **Name** text entry box.

Name
displays the name of the currently selected field function. You can enter a new name in this box if you want to rename the function.

ID
reports the ID number of the selected function. The field function at the top of the list has an ID of 0, the second function has an ID of 1, and so on.

Rename
changes the name of the selected function to the name specified in the **Name** text entry box.

Delete
deletes the selected field function.

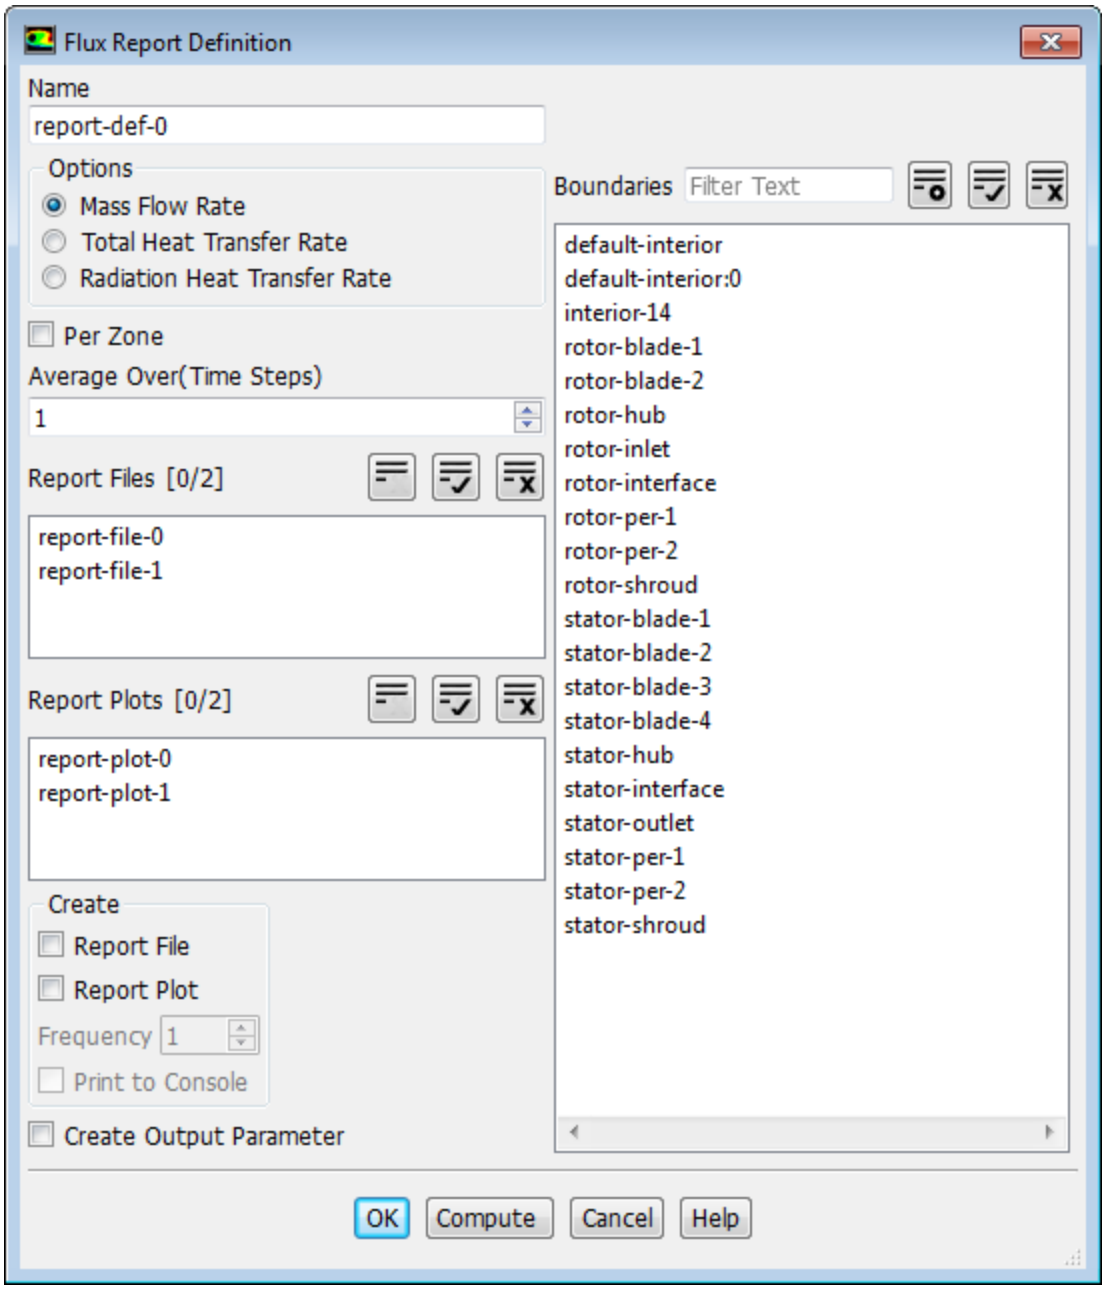
Save...
opens The Select File Dialog Box (p. 19), where you can specify a file in which to save all of the functions in the **Field Functions** list.

Load...
opens the **Select File** dialog box, where you can specify a file from which to read custom field functions (that is, a file that you saved using the **Save...** button above).

38.2.31. Flux Report Definition Dialog Box

Solving → Reports → Definitions → New → Flux Report

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Mass Flow Rate
turns on the computation of the mass flow rate for the selected boundary zones.

Total Heat Transfer Rate
turns on the computation of the total heat transfer rate for the selected boundary zones.

Total Sensible Heat Transfer Rate
turns on the computation of the total sensible heat transfer rate for the selected boundary zones. It reports the total energy flux as defined in Equation 5.2 in the Theory Guide.

Radiation Heat Transfer Rate
turns on the computation of the radiation heat transfer rate for the selected boundary zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Film Mass Flow Rate
(available only when the Eulerian wall film model is enabled) turns on the computation of the mass flow rate for the selected boundary zone(s).

Film Heat Transfer Rate
(available only when the Eulerian wall film model is enabled) turns on the computation of the film heat transfer rate for the selected boundary zone(s).

Phase
contains a list of all of the phases in the problem that you have defined. This is available when the VOF, mixture, or Eulerian multiphase model is enabled.

Per Zone
specifies whether or not the chosen field variable is calculated from all of the selected boundary zones combined (default) or individually on each of the selected boundary zones.

Average Over (Time-Steps), Average Over (Iterations)
(optional) To have Fluent calculate a running average for the **Flux Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Report Type
selects the integration method used on the selected cell zones. The available report types are the same as those in the Volume Integrals Dialog Box (p. 2620). See Volume Integration (p. 1922) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Boundaries
contains a selectable list of valid boundary zones for flux reporting.

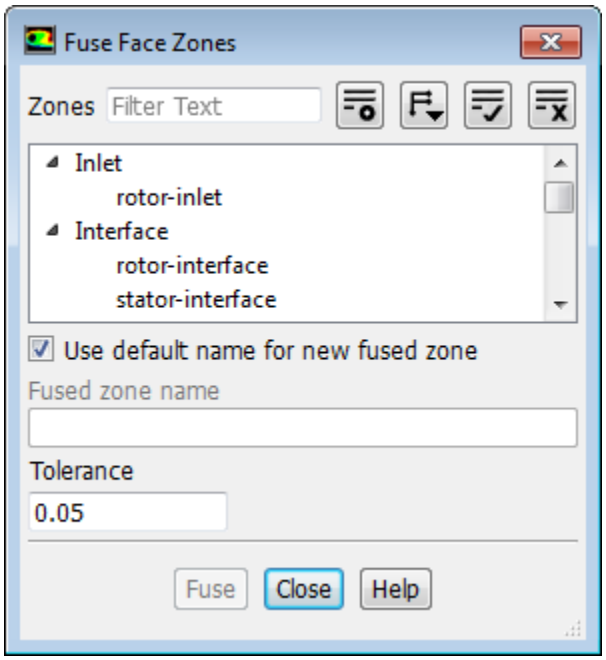
OK
creates the report definition.

Compute
computes the value of the report definition at the selected zone(s) and prints to the console.

38.2.32. Fuse Face Zones Dialog Box

The **Fuse Face Zones** dialog box allows you to fuse boundaries (that is, remove duplicate nodes and faces and delete artificial internal boundaries) created by assembling multiple mesh regions. (See Reading Multiple Mesh/Case/Data Files (p. 145) for details on importing such meshes.) See Fusing Face Zones (p. 212) for information about using this dialog box.

Setting Up Domain → Zones → Combine... → Fuse...



Controls

Zones
contains a list of face zones from which you can select the boundaries to be fused.

Use default name for new fused zone
specifies whether to use an automatically generated default name for the fused zone.

Fused zone name
specifies the desired name for the fused zone if **Use default name for new fused zone** is disabled.

Tolerance
is a fraction of the minimum edge length of the face, used to determine whether or not nodes are coincident. If all of the appropriate faces do not get fused using the default **Tolerance**, you should increase it and attempt to fuse the zones again. The **Tolerance** should not exceed 0.5, or you may fuse the wrong nodes.

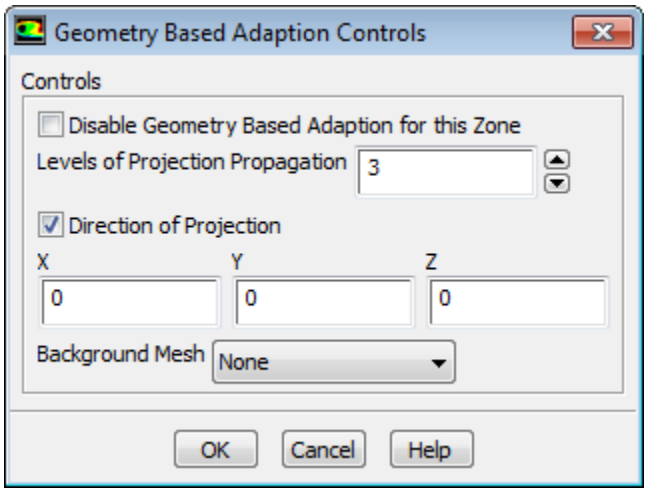
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fuse
fuses the selected zones. It is enabled only when you have selected a minimum of two zones.

38.2.33. Geometry Based Adaption Controls Dialog Box

The **Geometry Based Adaption Controls** dialog box allows you to set projections. See Performing Geometry-Based Adaption (p. 1699) for details about the items below.

The **Geometry Based Adaption Controls** dialog box is opened from the Geometry Based Adaption Dialog Box (p. 2709).



Controls

Controls
contains parameters to define geometry based adaption.

Disable Geometry Based Adaption for this Zone
disables the geometry reconstruction for selected zones in the domain.

Levels of Projection Propagation
is the number of layers of the nodes you want to project.

Direction of Projection
allows you to specify the direction in which you want to project the nodes.

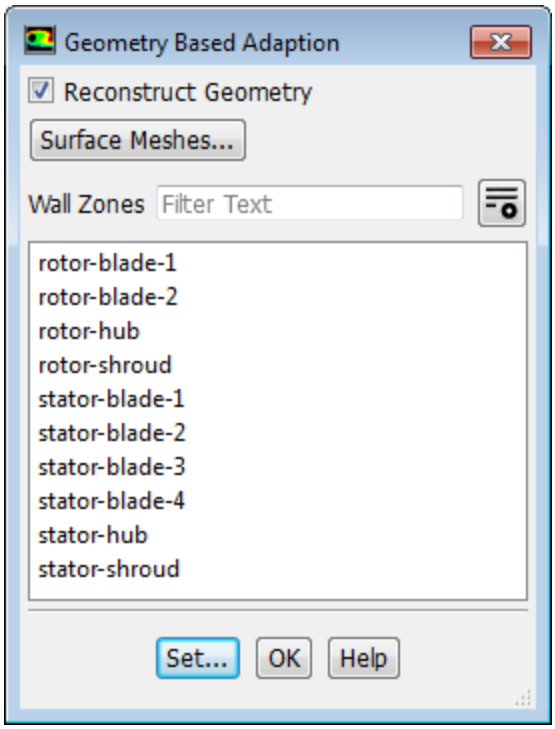
Background Mesh
allows you to load the surface mesh as a background mesh for adaption.

38.2.34. Geometry Based Adaption Dialog Box

The **Geometry Based Adaption** dialog box allows you to reconstruct the geometry while performing boundary adaption. See Geometry-Based Adaption (p. 1698) for details.

Setting Up Domain → Adapt → More → Geometry...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Reconstruct Geometry
enables geometry based adaption parameters.

Surface Meshes...
opens the Surface Meshes Dialog Box (p. 2807).

Wall Zones
allows you to select the wall zones you want to adapt.

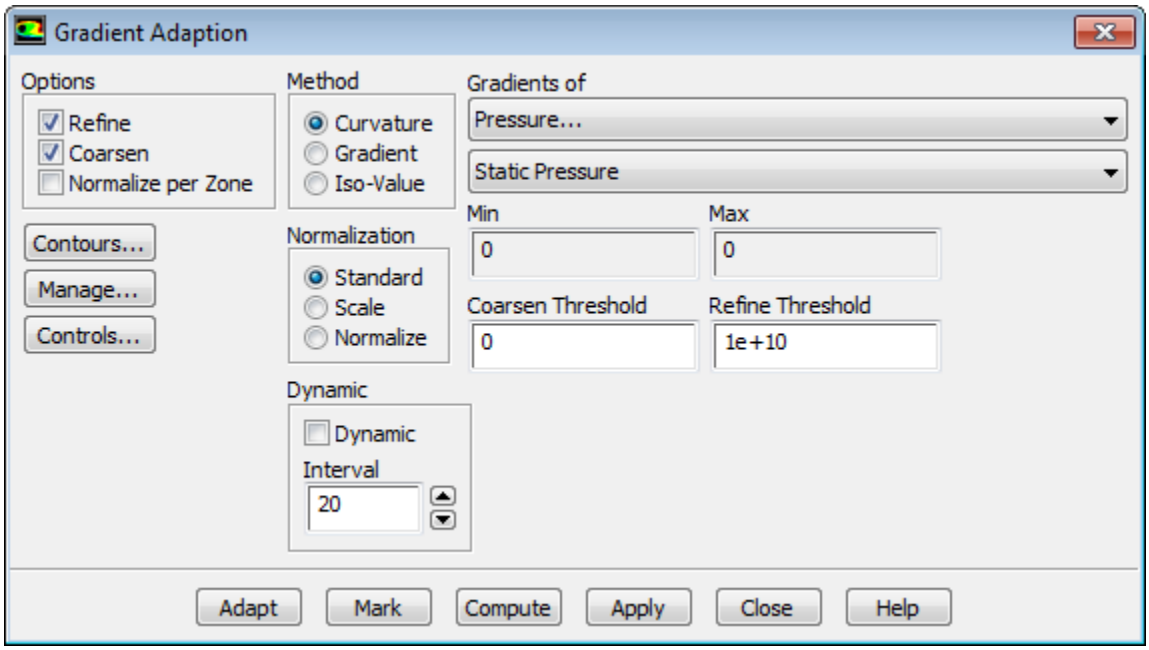
Set...
opens the Geometry Based Adaption Controls Dialog Box (p. 2709).

38.2.35. Gradient Adaption Dialog Box

The **Gradient Adaption** dialog box allows you to mark or adapt to gradients of a specified field variable. See Gradient Adaption (p. 1688) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Gradient...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains the check buttons that toggle the ability to mark and/or adapt cells for refinement or coarsening.

Refine
toggles the ability to refine or mark cells for refinement.

Coarsen
toggles the ability to coarsen or mark cells for coarsening (available in 2D and axisymmetric cases).

Normalize per Zone
toggles the ability of zonal normalization.

Contours...
opens the Contours Dialog Box (p. 2676), which you can use as an aid to selecting adaption thresholds by displaying contours of adaption function.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Method
contains options for specifying the criterion for adaption.

Curvature
specifies the use of the second gradient of a field variable for adaption. This approach is recommended for problems with smooth solutions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Gradient
specifies the use of the first gradient of a field variable for adaption. This approach is recommended for problems with strong shocks.

Iso-Value
allows you to customize the adaption criterion (using custom field functions, user-defined scalars, and so on).

Normalization
contains the options available for normalization.

Standard
specifies that the gradient or curvature is not normalized.

Scale
specifies that the gradient or curvature is scaled by its average value in the domain.

Normalize
specifies that the gradient or curvature is scaled by its maximum value in the domain (that is, the gradient or curvature is bounded by [0, 1]).

Dynamic
contains options to specify dynamic gradient adaption.

Dynamic
enables dynamic gradient adaption.

Interval
allows you to specify the number of iterations or time-steps between two consecutive automatic mesh adaptions, depending on whether you are performing a steady-state or a time-dependent solution, and on which solver you are using.

Gradients of
contains a list of the field variables that can be used in the gradient adaption function.

Min/Max
displays the minimum and maximum cell values of the gradient adaption function based on the selected quantity.

Coarsen Threshold
designates the threshold values for coarsening the mesh. Cells with adaption function values below the **Coarsen Threshold** will be marked for coarsening.

Refine Threshold
designates the threshold values for refining the mesh. Cells with adaption function values above the **Refine Threshold** will be marked for refinement.

Adapt
adapts the mesh based on the gradients of the selected scalar quantity, the coarsening and refining toggle buttons and thresholds, and the adaption limits.

Mark
marks cells to be refined and/or coarsened based on the gradients of the selected quantity and the coarsening and refining toggle buttons and thresholds. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

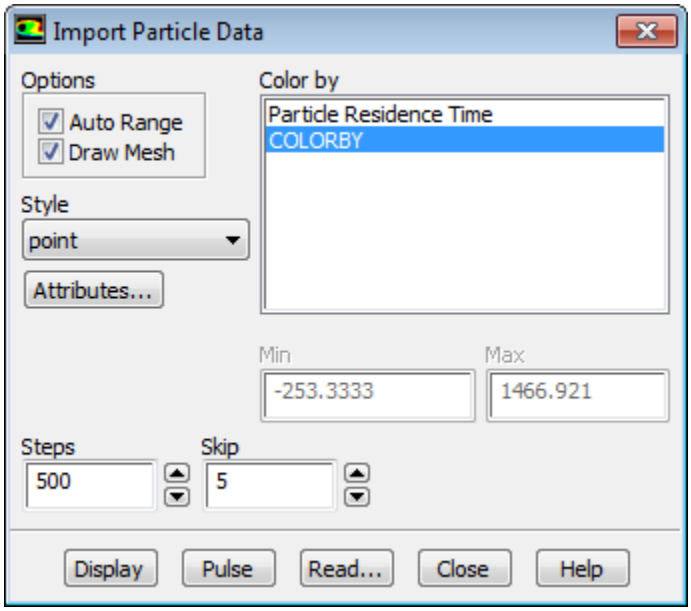
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Compute
computes the minimum and maximum cell values of the gradient adaption function with the selected scalar quantity. The values are displayed in the **Min** and **Max** real number fields.

38.2.36. Import Particle Data Dialog Box

The **Import Particle Data** dialog box allows you to import particle history data for display purposes. See Importing Particle Data (p. 1338) for details.

Postprocessing → Model Specific → Discrete Phase → Import Particle Data...



Controls

Options
contains the check buttons that set various import particle data options.

Auto Range
toggles between automatic and manual setting of the particle data range.

Draw Mesh
toggles between displaying and not displaying the mesh. The Mesh Display Dialog Box (p. 2163) is opened when **Draw Mesh** is selected.

Style
allows you to select pathline style.

Attributes...
opens the Path Style Attributes Dialog Box (p. 2559). This allows you to modify the line width, cylinder radius or marker size.

Color by
contains a list from which you can select the scalar field to be used to color the particle data.

Min,Max
allows you to set the range when **Auto Range** is disabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Steps
sets the maximum number of steps a particle can advance.

Skip
allows you to "thin out" the pathlines.

Display
displays pathlines.

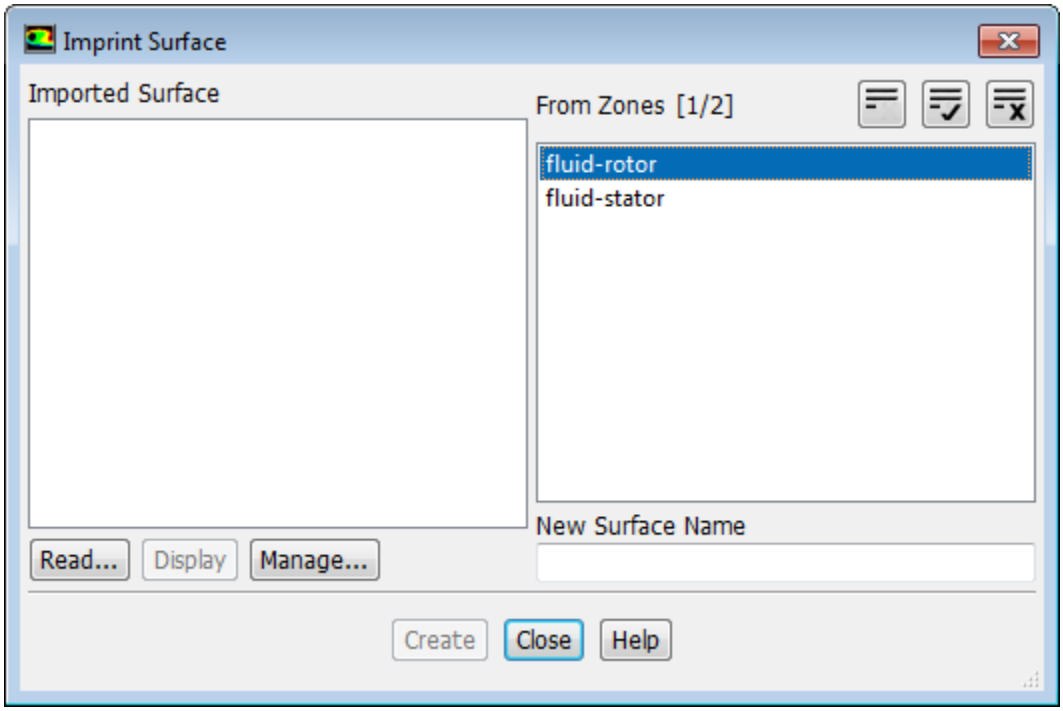
Pulse
animates the particle positions. The **Pulse** button will become the **Stop !** button during the animation, and you must click **Stop !** to stop the pulsing.

Read...
opens a file selection dialog box where you can enter a file name and a directory for the imported data.

38.2.37. Imprint Surface Dialog Box

The **Imprint Surface** dialog box allows you to define a surface on top of an existing cell zone for postprocessing purposes. See Imprint Surfaces (p. 1714) for details about the following items.

Setting Up Domain → Surface → Create → Imprint...



Controls

Imported Surface
lists the surfaces that you have imported.

Read...
opens The Select File Dialog Box (p. 19), so that you can select surface files for import.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Display
allows you to display the selected surfaces.

Manage...
opens the Surfaces Dialog Box (p. 2810), where you can rename and delete surfaces and determine their sizes.

New Surface Name
designates the name of the new surface. The default name format is `<original-name>(imprint)-<id>`.

From Zones
allows you to select the zones where you want to import/imprint the surface mesh.

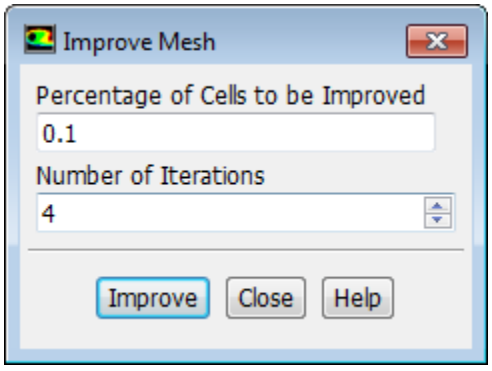
> **Note**
>
> If no zone is selected, then the entire domain is considered.

Create
creates the new surface, imprinted with the mesh of the selected cell zone.

38.2.38. Improve Mesh Dialog Box

The **Improve Mesh** dialog box controls the quality-based smoothing of the numerical mesh. See Improving the Mesh by Smoothing and Swapping (p. 230) for details about the items below.

Setting Up Domain → Mesh → Improve...



Controls

Percentage of Cells to be Improved
sets the percentage of the total cells on which improvements are attempted. Note that the cells selected for improvement are in the areas of the mesh that exhibit the lowest orthogonal quality.

Number of Iterations
defines the number of successive smoothing sweeps performed on the mesh.

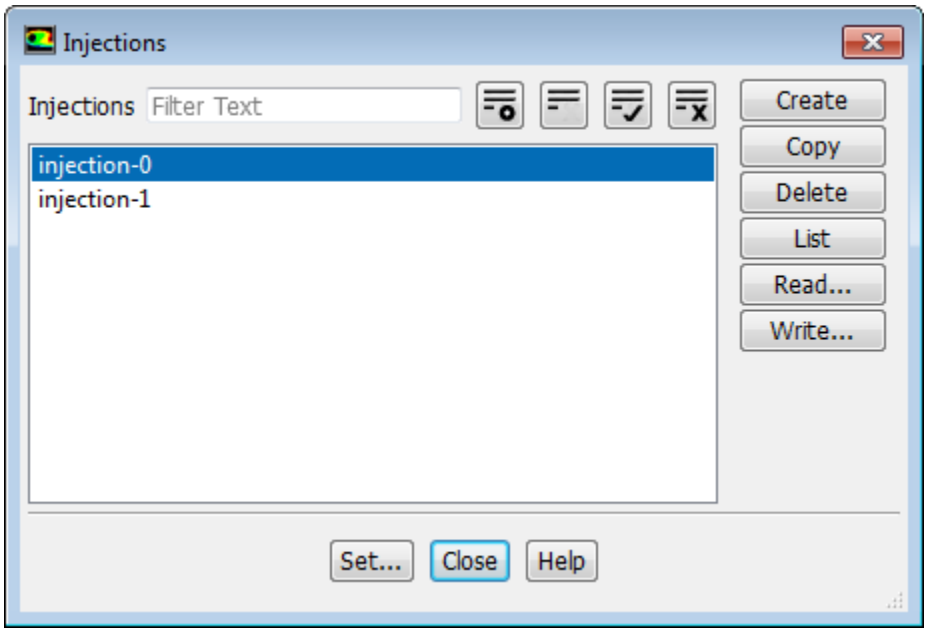
Improve
initiates the desired number of smoothing iterations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.39. Injections Dialog Box

The **Injections** dialog box allows you to create, delete, and list discrete phase injections, and access the Set Injection Properties Dialog Box (p. 2796) and the Set Multiple Injection Properties Dialog Box (p. 2803), in which you can set the properties for the injections. See Creating and Modifying Injections (p. 1284) for details.

Setting Up Physics → Model Specific → Discrete Phase → Injections...



Controls

Injections
contains a list from which you can select one or more injections in order to set, copy, or modify properties, or delete or list injections.

Create
creates a new injection and opens the Set Injection Properties Dialog Box (p. 2796), in which you can set its properties.

Copy
creates a new injection with the same properties as the selected injection and opens the Set Injection Properties Dialog Box (p. 2796) where the new injection's properties can be modified.

Delete
deletes the injection(s) selected in the **Injections** list.

List
lists the initial conditions for the particle streams in the injection(s) selected in the **Injections** list.

Read...
opens The Select File Dialog Box (p. 19) where you will select the injection file to read in.

Write...
allows you to select the injection from the list and write it to a file.

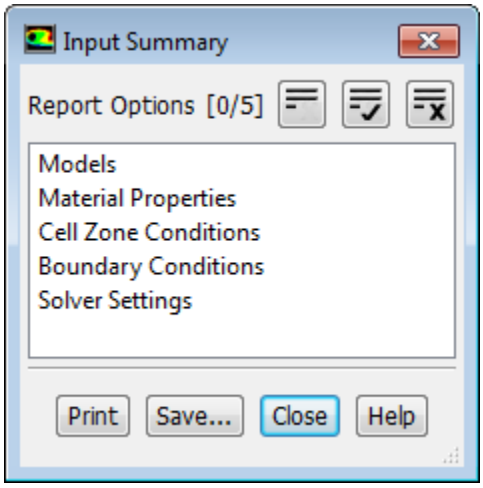
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set...
opens the Set Injection Properties Dialog Box (p. 2796) for the injection selected in the **Injections** list or the Set Multiple Injection Properties Dialog Box (p. 2803) if more than one injection is selected in the **Injections** list.

38.2.40. Input Summary Dialog Box

The **Input Summary** dialog box allows you to report the current settings for physical models, boundary conditions, material properties, and solution parameters. See Generating a Summary Report (p. 1927) for details about the items below.

Solving → Run Calculation → Input Summary...



Controls

Report Options
contains a selectable list of the information that is available for the report.

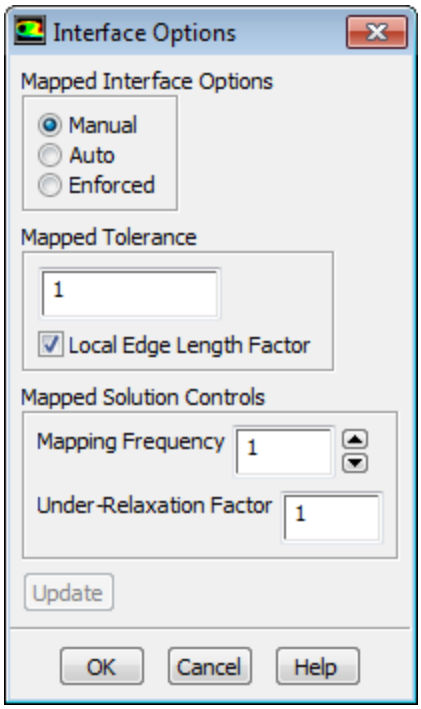
Print
prints the selected information to the console.

Save...
opens The Select File Dialog Box (p. 19), in which you can specify the filename under which to save the output of the summary report.

38.2.41. Interface Options Dialog Box

The **Interface Options** dialog box allows you to update which mesh interfaces use the mapped option and the related settings (see The Mapped Option (p. 158) for additional information). It is opened by clicking the **Options...** button in the **Mesh Interfaces** group box of the Mesh Interfaces Dialog Box (p. 2732).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Mapped Interface Options
contains options related to mapped interface specification.

Manual
specifies that the only **Mapped** mesh interfaces are the ones that you have defined as **Mapped** in the **Edit Mesh Interfaces** dialog box.

Auto
specifies that all mesh interfaces that have interface zones that penetrate each other are automatically defined as **Mapped** interfaces.

Enforced
specifies all mesh interfaces as **Mapped** interfaces. Fluent creates the mapped interfaces regardless of the mesh quality.

Mapped Tolerance

Local Edge Length Factor
creates mapping based on local mesh size. The default factor is **1**. Disabling **Local Edge Length Factor** allows you to specify an absolute value for the tolerance that is used in determining the search range for mapping. Note that this does not overwrite any locally specified tolerance in the **Edit Mesh Interfaces** dialog box.

Mapped Solution Controls

Mapping Frequency
specifies how often calculation values are interpolated across mapped interfaces.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Under-Relaxation Factor
allows you to reduce the rate of change per iteration of physical quantities across mapped interfaces to aid with convergence. For additional information on setting under-relaxation factors, see Setting Under-Relaxation Factors (p. 1564).

Update
applies the selection(s) made in the **Interface Options** dialog box. This button is grayed-out until you make a selection in the **Mapped Interface Options** or **Mapped Tolerance** group boxes; it also returns to being grayed-out once it is clicked.

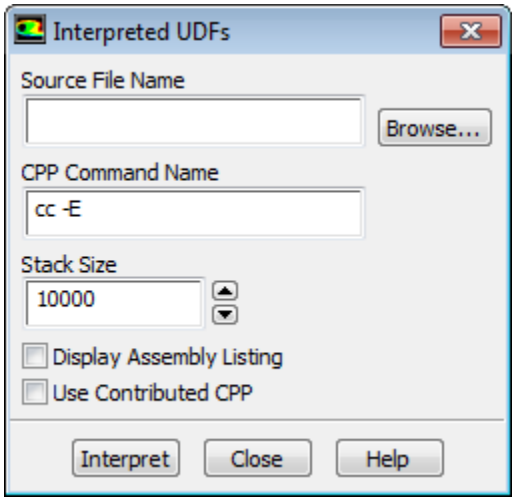
Note

Selecting **Auto** or **Enforced** and clicking **Update** applies these selections globally for all relevant interfaces. Once you click **Update** you can return to the **Mesh Interfaces** dialog box to modify local settings for individual interfaces.

38.2.42. Interpreted UDFs Dialog Box

The **Interpreted UDFs** dialog box allows you to compile user-defined functions. See the separate Fluent Customization Manual for details.

User Defined → **User Defined** → **Functions** → **Interpreted...**



Controls

Source File Name
sets the name of your user-defined function.

CPP Command Name
sets the name of your C preprocessor.

Stack Size
sets the size of the stack. Keep the default **Stack Size** setting of 10000, unless the number of local variables in your function will cause the stack to overflow. In this case, set the **Stack Size** to a number that is greater than the number of local variables used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

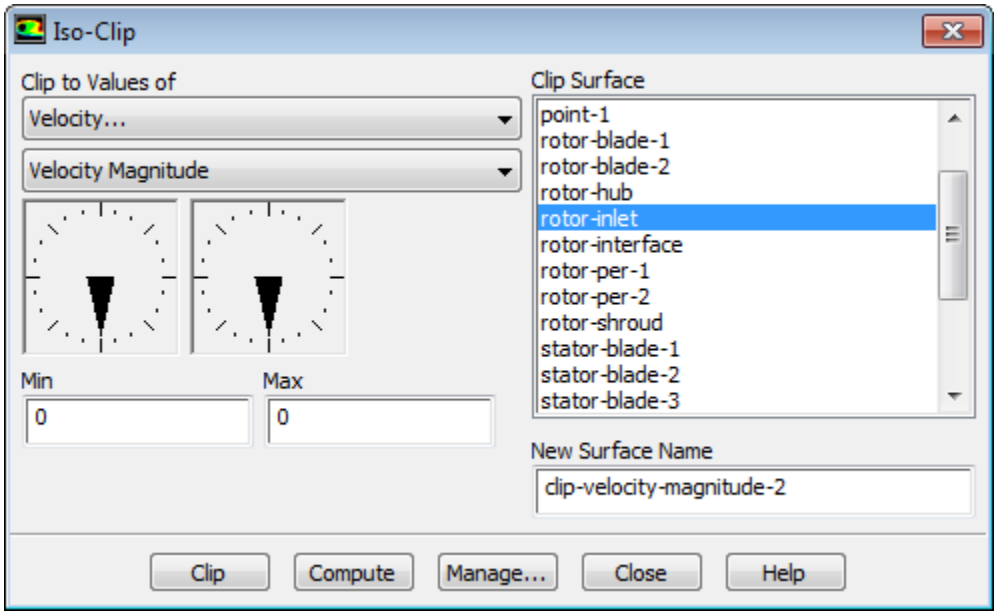
Display Assembly Listing
indicates whether or not to display a listing of assembly language code in your console window as the function compiles.

Use Contributed CPP
specifies the use of the C preprocessor that ANSYS Fluent has supplied, instead of your own.

Interpret
interprets the specified function.

38.2.43. Iso-Clip Dialog Box

The **Iso-Clip** dialog box allows you to interactively clip surfaces. The clipped surface consists of those points on the selected surface where the scalar field values are within the specified range. See Clipping Surfaces (p. 1730) for details about the items below.



Controls

Clip to Values of
contains a list from which you can select the scalar field to be used for clipping.

Phase
allows you to select the phase when one of the multiphase models is selected in the Multiphase Model Dialog Box (p. 2171).

Min, Max
set the minimum and maximum values in the clipping range. There are two ways you can set the **Min** and **Max**:

- You can set a value interactively by moving the indicator in the dial above the **Min** or **Max** field with the left mouse button. This will also create a temporary surface in the graphics window. Using the dial allows you to preview the clipped surfaces before defining them. Note: Even though the clipped surface is displayed, it is only a temporary surface. To clip the surface, use the **Clip** button after deciding on the minimum and maximum values.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- You can type in values in the **Min** and **Max** fields directly.

Clip Surface
contains a list of surfaces from which you can select the surface to be clipped. You must select a surface to make the **Clip** button available.

New Surface Name
designates the name of the surface to be created. The default is the concatenation of the surface type and an integer which is the new surface ID.

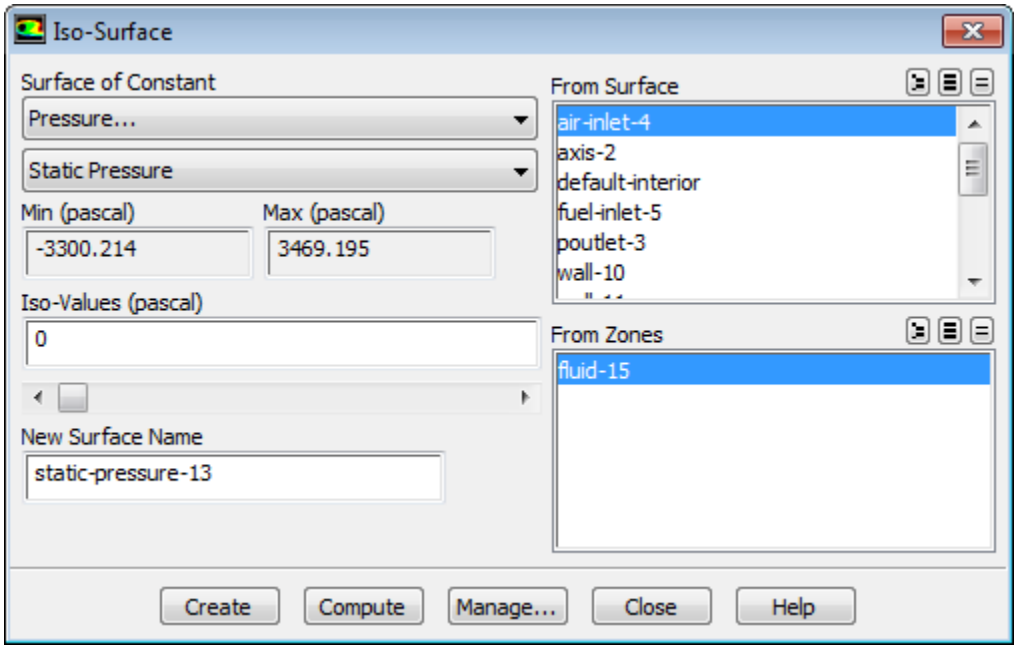
Clip
creates the clipped surface. (The original surface will remain unchanged.)

Compute
computes the minimum and maximum values of the scalar field across the domain, and displays them in the **Min** and **Max** boxes.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

38.2.44. Iso-Surface Dialog Box

The **Iso-Surface** dialog box allows you to interactively create isosurfaces. These surfaces can be isovalued sections of an existing surface or of the entire domain. For more effective use of the slider bar, press the **Compute** button before using it. See Isosurfaces (p. 1728) for details about the items below.



Controls

Surface of Constant
contains a list from which you can select the scalar field which will be used for isosurfacing.

Min
displays the minimum field value, which is computed when you click **Compute**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Max
displays the maximum field value, which is computed when you click **Compute**.

Iso-Values
sets user-specified isovalues. There are two ways you can set the **Iso-Values**:

- You can set an isovalue interactively by moving the slider with the left mouse button. This will also create a temporary isosurface in the graphics window. Using the slider allows you to preview the isosurfaces before defining them. Note: Even though the isosurface is displayed, it is only a temporary surface. To create an isosurface, use the **Create** button after deciding on a particular isovalue.
- You can type in isovalues in the **Iso-Values** field directly, separating multiple values by white space. Multiple isovalues will be contained in a single isosurface; that is, you cannot select subsurfaces within the resulting isosurface.

From Surface
contains a list of existing surfaces from which you can select the surface to be used for isosurfacing. If you do not select a surface from the list, the isosurfacing will be performed on the entire domain.

From Zones
contains a list of cell zones from which you can select the zone for creating an isosurface.

New Surface Name
designates the name of the surface to be created. The default is the concatenation of the scalar field name and an integer which is the new surface ID.

Create
creates the surface.

Compute
computes the minimum and maximum of the scalar field across the domain and displays them in the **Min** and **Max** boxes.

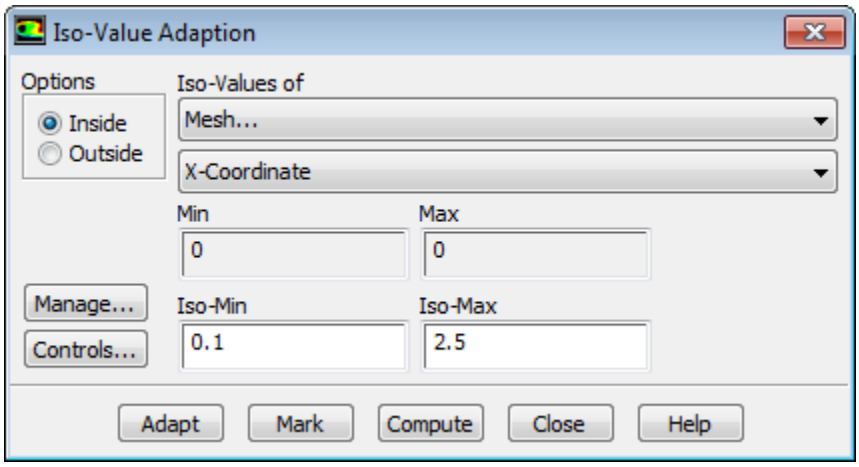
Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

38.2.45. Iso-Value Adaption Dialog Box

The **Iso-Value Adaption** dialog box allows you to mark or refine cells inside or outside a specified range of a selected scalar function. See Isovalue Adaption (p. 1691) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Iso-Value...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains radio buttons that control whether the cells inside or outside the isovalue range are marked for refinement.

Inside
enables the marking of cells with values between **Iso-Min** and **Iso-Max**.

Outside
enables the marking of cells with values less than **Iso-Min** or greater than **Iso-Max**.

Iso-Values of
contains a list from which you can select the solution variable to be used in the isovalue adaption function.

Min/Max
displays the minimum and maximum cell values of the selected field variable. The real number field values are not editable; they are purely informational.

Iso-Min
defines the minimum isovalue threshold.

Iso-Max
defines the maximum isovalue threshold.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Adapt
adapts the mesh based on the isovalues of the selected solution variable, the isovalue ranges, and the **Inside/Outside** option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mark

marks cells to be refined based on the isovalues of the selected quantity, the isovalue ranges, and the **Inside/Outside** option. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

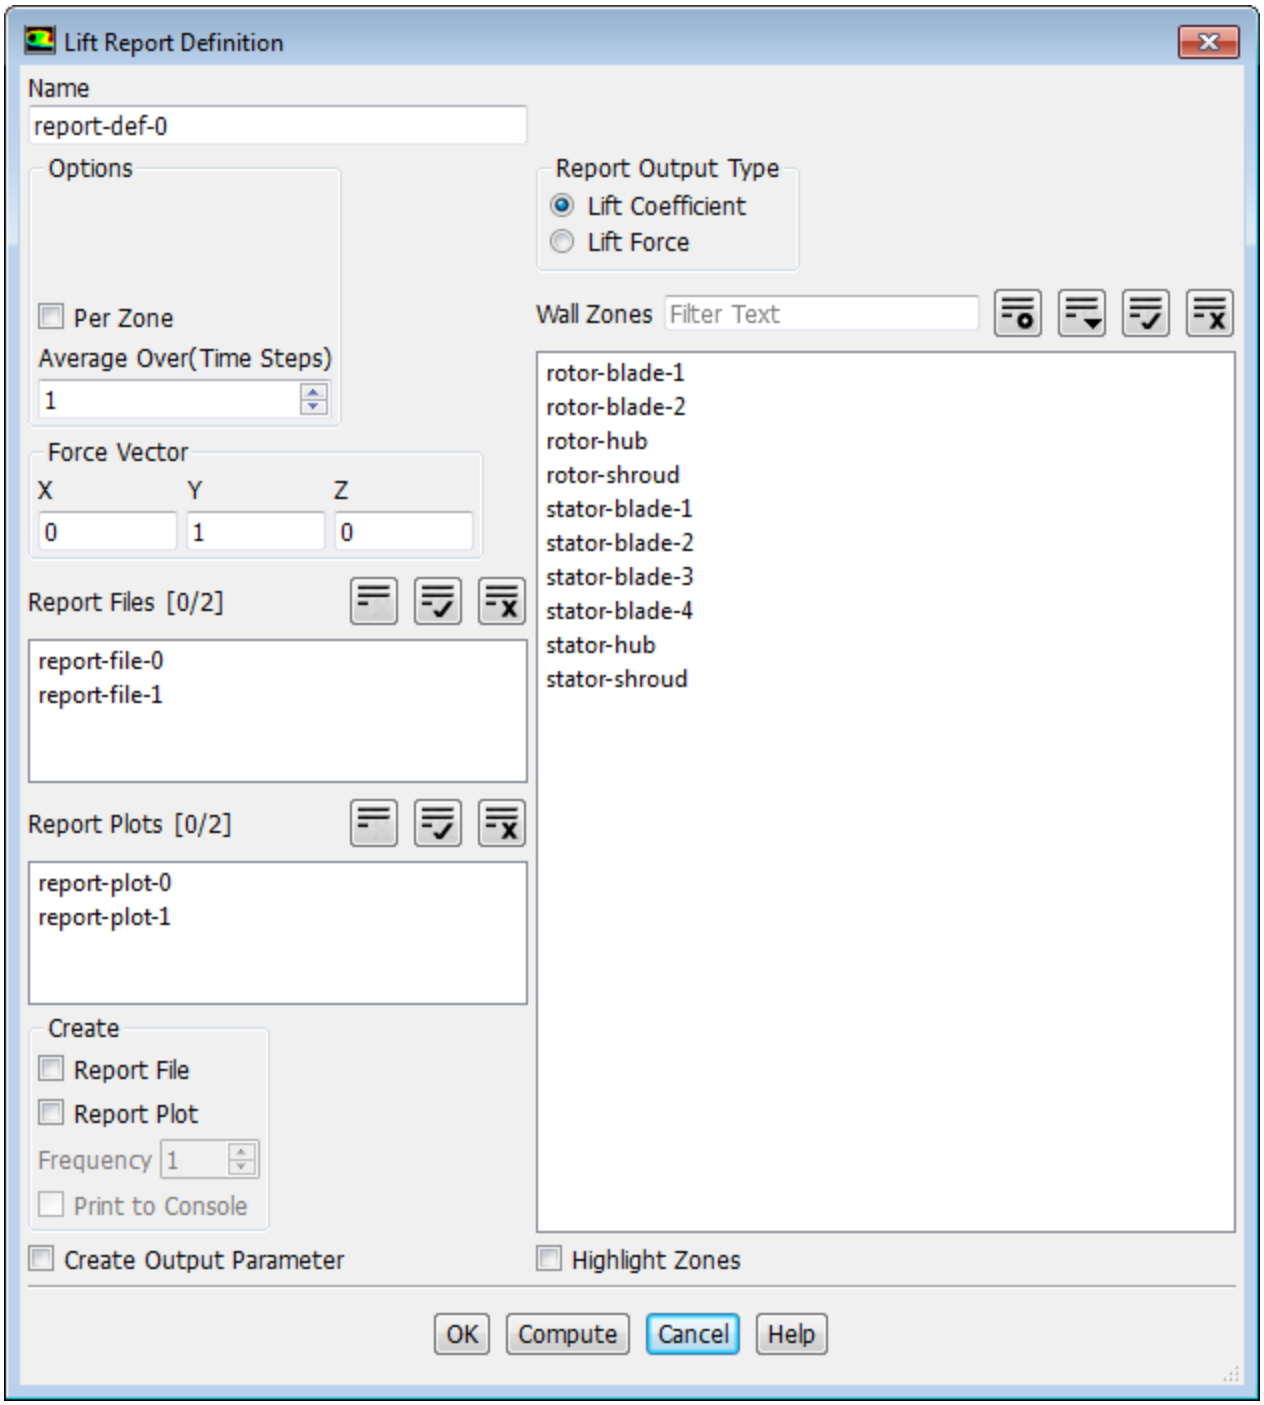
Compute

computes the minimum and maximum cell values of the selected solution variable and displays them in the **Min** and **Max** real number fields.

38.2.46. Lift Report Definition Dialog Box

Solving → **Reports** → **Definitions** → **New** → **Force Report** → **Lift...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Per Zone

specifies whether or not the lift for multiple walls zones should be monitored on each wall zone separately.When this option is turned off (the default), Fluent computes and monitors the total lift for all of the selected walls zones combined together.

Average Over (Time-Steps), Average Over (Iterations)

(optional) To have Fluent calculate a running average for the **Lift Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Force Vector
contains the components of the force vector.

X,Y,Z
are the components of the force vector along which the forces will be computed.

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Report Output Type

Lift Coefficient
specifies the report definition as a unitless quantity.

Lift Force
specifies that the report definition has units of force.

Wall Zones
lists the zones you can select for lift coefficient or drag lift computation.

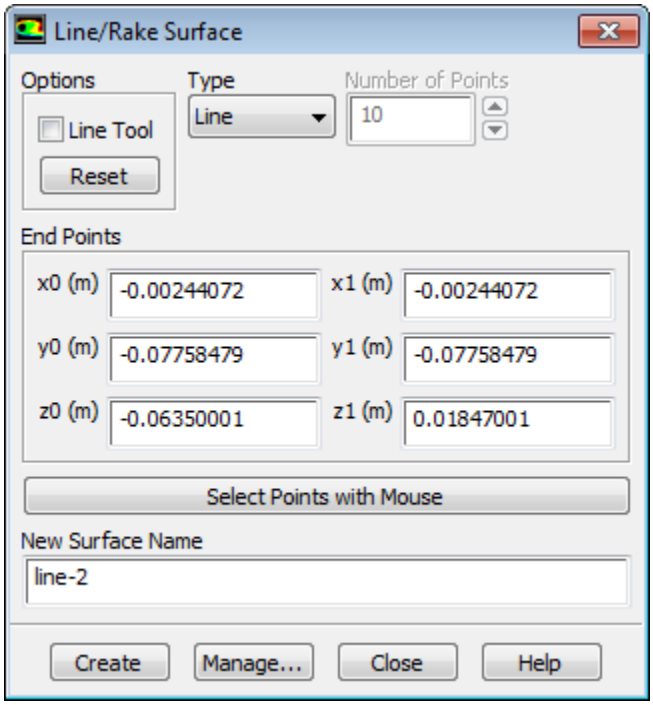
OK
creates the report definition.

Compute
computes the value of the report definition at the selected zone(s) and prints to the console.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.47. Line/Rake Surface Dialog Box

The **Line/Rake Surface** dialog box allows you to interactively create line and rake surfaces. A rake is a linear, uniform distribution of points between two endpoints. See Line and Rake Surfaces (p. 1718) for details about the items below.



Controls

Options
contains options related to the line tool. See Using the Line Tool (p. 1720) for details about using this feature.

Line Tool
enables the line tool.

Reset
resets the line tool to its default position.

Type
selects line or rake as the surface to be created.

Number of Points
defines the number of points in the rake surface (inactive for line surfaces).

End Points
designates the coordinates of the first point (**x0**, **y0**, **z0**) and the last point (**x1**, **y1**, **z1**).

Select Points with Mouse
allows you to select endpoints with the mouse. You can select endpoints by clicking on locations in the active window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

New Surface Name
designates the name of the new surface. The default is the concatenation of the surface type and an integer which is the new surface ID.

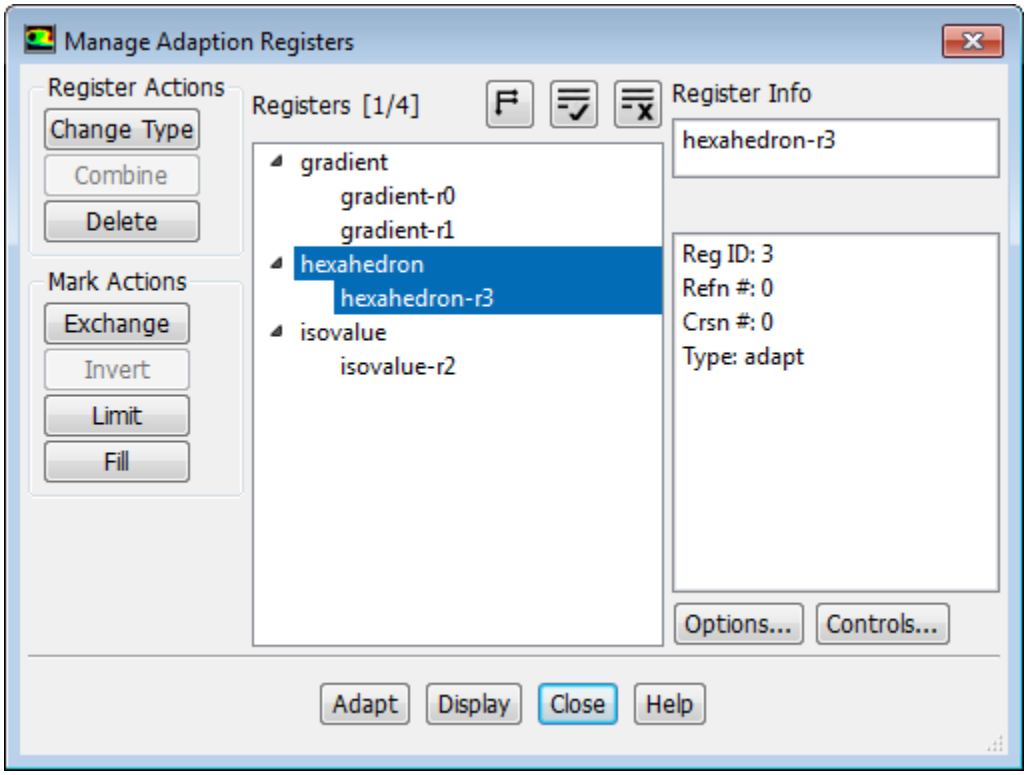
Create
creates the surface.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

38.2.48. Manage Adaption Registers Dialog Box

The **Manage Adaption Registers** dialog box provides an interactive mechanism for creating, destroying, and displaying functions for mesh adaption. See Manipulating Adaption Registers (p. 1701) for details about using the items in this dialog box.

Setting Up Domain → Adapt → Manage Registers...



Controls

Register Actions
contains operations applied to adaption or mask registers.

Change Type
toggles the register between adaption and mask types. Adaption registers are used to initiate refining or coarsening of the mesh. Typically, mask registers are combined with adaption registers to control the scope of the adaption process.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Combine
combines the selected adaption registers to create a hybrid adaption function. In some instances, three new registers may be created: a combination of the adaption registers, a combination of the mask registers, and then a combination of the two combined registers.

Delete
permanently discards the selected registers.

Mark Actions
contains operations applied to the cell markings defined in an adaption or mask register.

Exchange
modifies the cell markings in the following manner: all cells originally marked for refinement are marked for coarsening, and all cells originally marked for coarsening are marked for refinement.

Invert
modifies all the cell markings in a mask register in the following manner: all cells that were originally marked as ACTIVE are marked INACTIVE, and all cells originally marked as INACTIVE are marked ACTIVE. Note that this action can only be applied to mask registers.

Limit
applies the adaption volume limits to the selected registers. For information on adaption limits, see Mesh Adaption Controls (p. 1705).

Fill
marks for coarsening all cells in the adaption register that are not marked for refinement.

Registers
contains a list from which you can select the current adaption and mask registers. The availability of many of the actions in the dialog box is based on the number and/or type of adaption registers selected.

Register Info
provides the name, ID, number of cells marked for refinement and coarsening, and the type of the most recently selected or deselected register.

Options...
opens the Adaption Display Options Dialog Box (p. 2663).

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Adapt
adapts the mesh based on the selected adaption register. The **Adapt** button is not available if more than one adaption register is selected. Adaption functions composed of combinations of adaption registers can be produced using commands in the **Register Actions** and **Mark Actions** boxes.

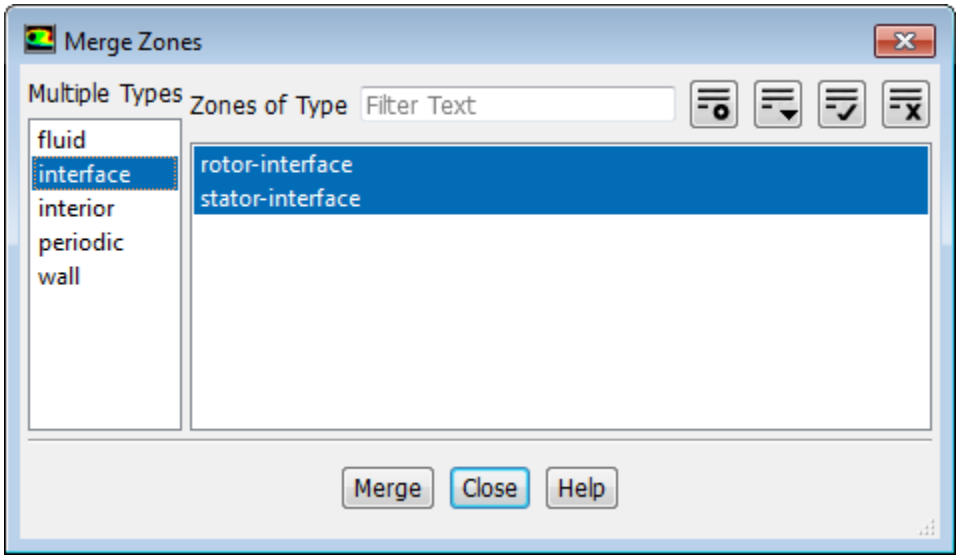
Display
displays the cells marked for adaption in the selected adaption register in the active graphics window. The **Display** button is not available if more than one adaption register is selected. Adaption functions composed of combinations of adaption registers can be produced using commands in the **Register Actions** and **Mark Actions** boxes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.49. Merge Zones Dialog Box

The **Merge Zones** dialog box allows you to merge multiple zones of the same type into a single zone. See Merging Zones (p. 206) for details.

Setting Up Domain → Zones → Combine → Merge...



Controls

Multiple Types
contains a selectable list of the zone types for which you can merge multiple zones. You select a type and the corresponding zones of that type will be displayed in the **Zones of Type** list.

Zones of Type
contains a list from which you can select two or more zones to be merged into a single zone. The zones are of the type selected in the **Multiple Types** list.

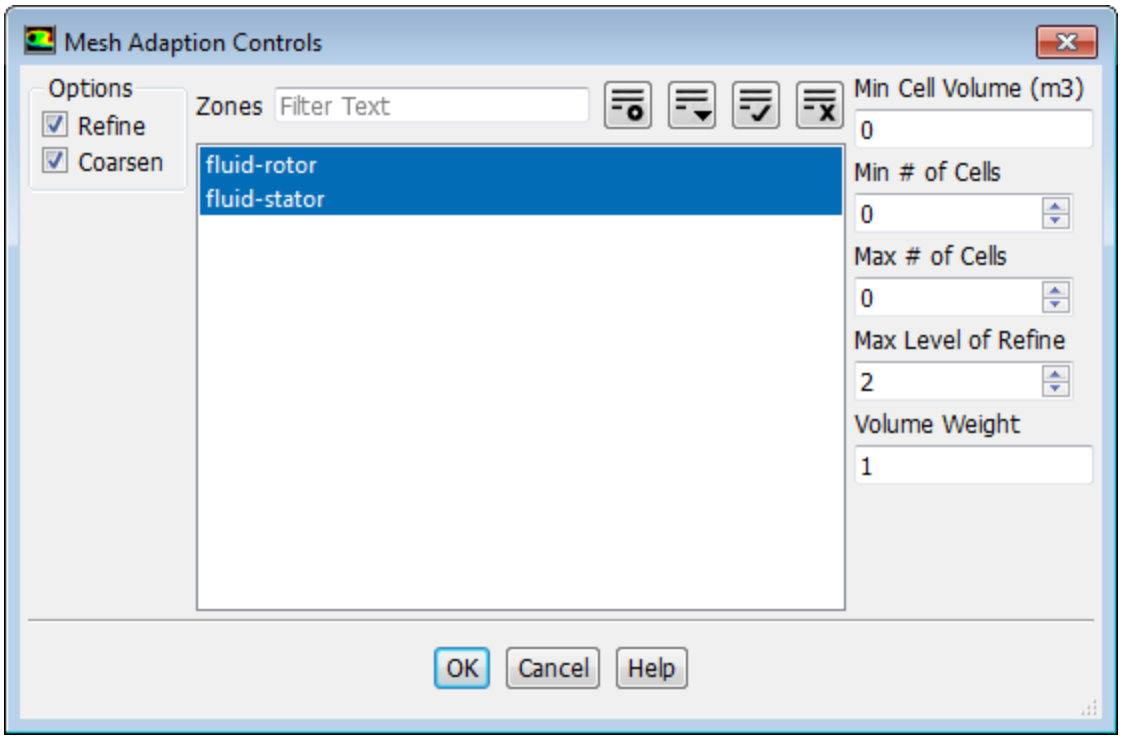
Merge
merges the selected zones into a single zone. If your case file has dynamic zones or mesh interfaces, the Warning Dialog Box (p. 2841) will open and require your input prior to the merge.

38.2.50. Mesh Adaption Controls Dialog Box

The **Mesh Adaption Controls** dialog box allows you to set limits on the minimum cell size, the minimum and maximum number of cells, and the cell types that can be adapted. In addition, it allows you to vary the volume weighting of the gradient adaption function. See Mesh Adaption Controls (p. 1705) for details about the items below.

Setting Up Domain → Adapt → More → Controls...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains check buttons that control the manner in which the mesh can be adapted.

Refine
toggles mesh adaption by adding points.

Coarsen
toggles mesh adaption by removing points.

Zones
contains a list of cell zones from which you can select the zones in which to perform adaption (or marking). By default, all cell zones are selected.

Min Cell Volume
restricts the size of the cell that is considered for refinement. Even if the cell is marked for refinement, it will not be refined if its cell volume is less than this threshold value.

Min # of Cells
specifies the minimum number of cells required in the mesh.

Note

When using the parallel solver, the **Min # of Cells** value is not strictly obeyed, but provides an approximate limit to the minimum cell count that the adaption algorithm will allow.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Max # of Cells
limits the total number of cells allowed in the mesh. A value of zero places no limits on the number of cells.

> **Note**
>
> When using the parallel solver, the **Max # of Cells** value is not strictly obeyed, but provides an approximate limit to the maximum cell count that the adaption algorithm will allow.

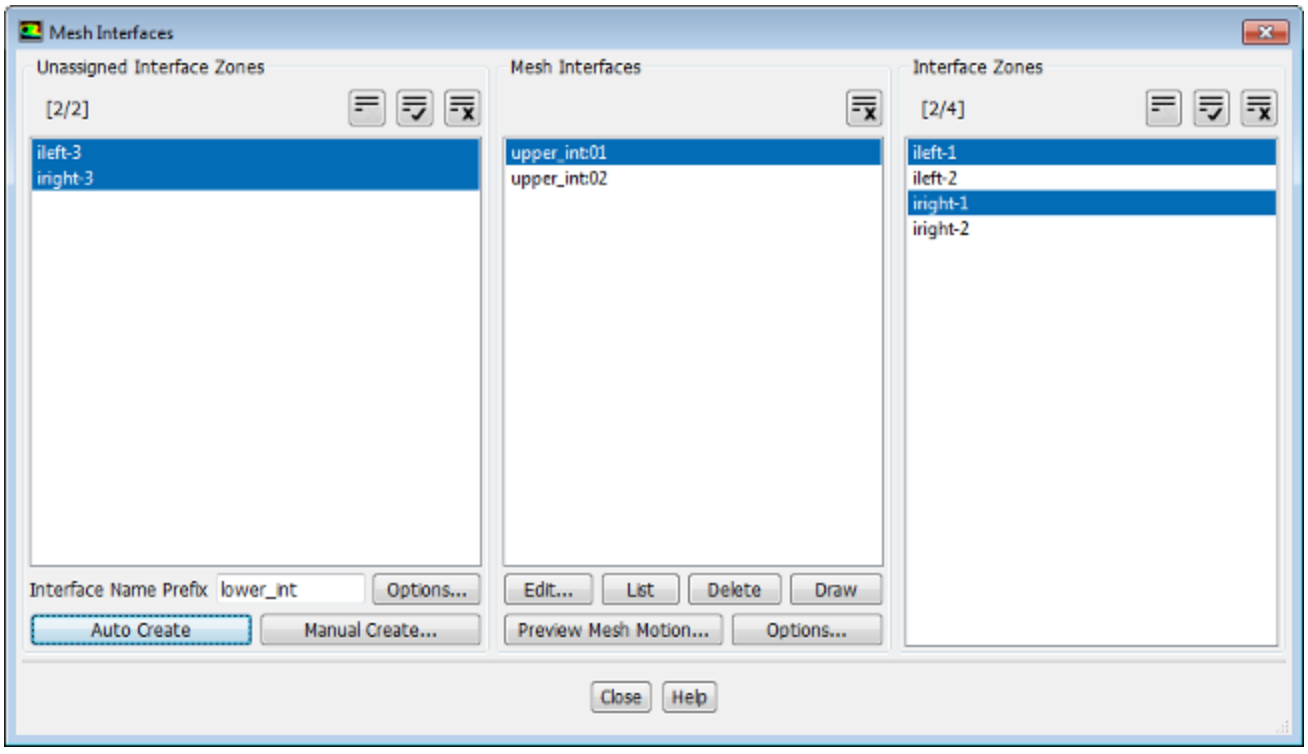
Max Level of Refine
specifies the maximum level of refinement for the cells.

Volume Weight
controls the volume weighting in the gradient adaption function. Valid values are between 0 and 1: 0 for no volume weighting and 1 for full volume weighting.

38.2.51. Mesh Interfaces Dialog Box

The **Mesh Interfaces** dialog box allows you to automatically or manually create mesh interfaces for use with sliding meshes (see Using Sliding Meshes (p. 633)) or multiple reference frames (see Mesh Setup for a Multiple Moving Reference Frame (p. 616)), or for meshes with non-conformal boundaries (see Non-Conformal Meshes (p. 150)). For information about using this dialog box, see Using a Non-Conformal Mesh in ANSYS Fluent (p. 164).

Setting Up Domain → Interfaces → Mesh...



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Unassigned Interface Zones

allows you to create new mesh interfaces using the automatic or manual method. Note that the selection list at the top of the group box (which lists interface zones that have not yet been assigned to an existing mesh interface) is only used as part of the automatic method.

Interface Name Prefix

specifies the prefix used in the names of all the mesh interfaces created automatically through the **Auto Create** button.

Options...

opens the Auto Create Options Dialog Box (p. 2672), so you can define settings that you want applied to the mesh interfaces that are created automatically through the **Auto Create** button.

Auto Create

creates mesh interfaces using the automatic method, so that Fluent is responsible for determining which of the selected **Unassigned Interface Zones** can be grouped together to form the two sides of one or more mesh interfaces. Note that mesh interfaces that use the periodic or periodic repeat option cannot be created using this button, but must instead be created through the **Manual Create...** button.

Manual Create...

opens the Create/Edit Mesh Interfaces Dialog Box (p. 2680), so you can create mesh interfaces using the manual method. Note that this method is only necessary for mesh interfaces that use the periodic or periodic repeat option.

Mesh Interfaces

allows you to manage existing mesh interfaces. Note that many of the buttons in this group box are not accessible unless you make a selection from the list at the top.

Edit...

opens the Edit Mesh Interfaces Dialog Box (p. 2696), so you can edit the name, the list of interface zones assigned to the interface, and/or the interface options.

List

prints information about the selected mesh interface in the console. When you click this button, ANSYS Fluent will list the two interface boundaries and (if you have initialized the solution) all new zones that were created (that is, wall and/or interior zones).

Delete

deletes the selected mesh interface. Note that this button can only be used on one mesh interface at a time; if you would instead like to delete multiple interfaces in a single action, you can select them in the tree and use the right-click menu command.

Draw

allows you to display the selected mesh interface (along with any additional selections in the **Unassigned Interface Zones** and/or **Interface Zones** lists) in the graphics window.

Preview Mesh Motion...

opens the Mesh Motion Dialog Box (p. 2500).

Options...

opens the Interface Options Dialog Box (p. 2717), where you can set global parameters for mapped mesh interfaces.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Interface Zones

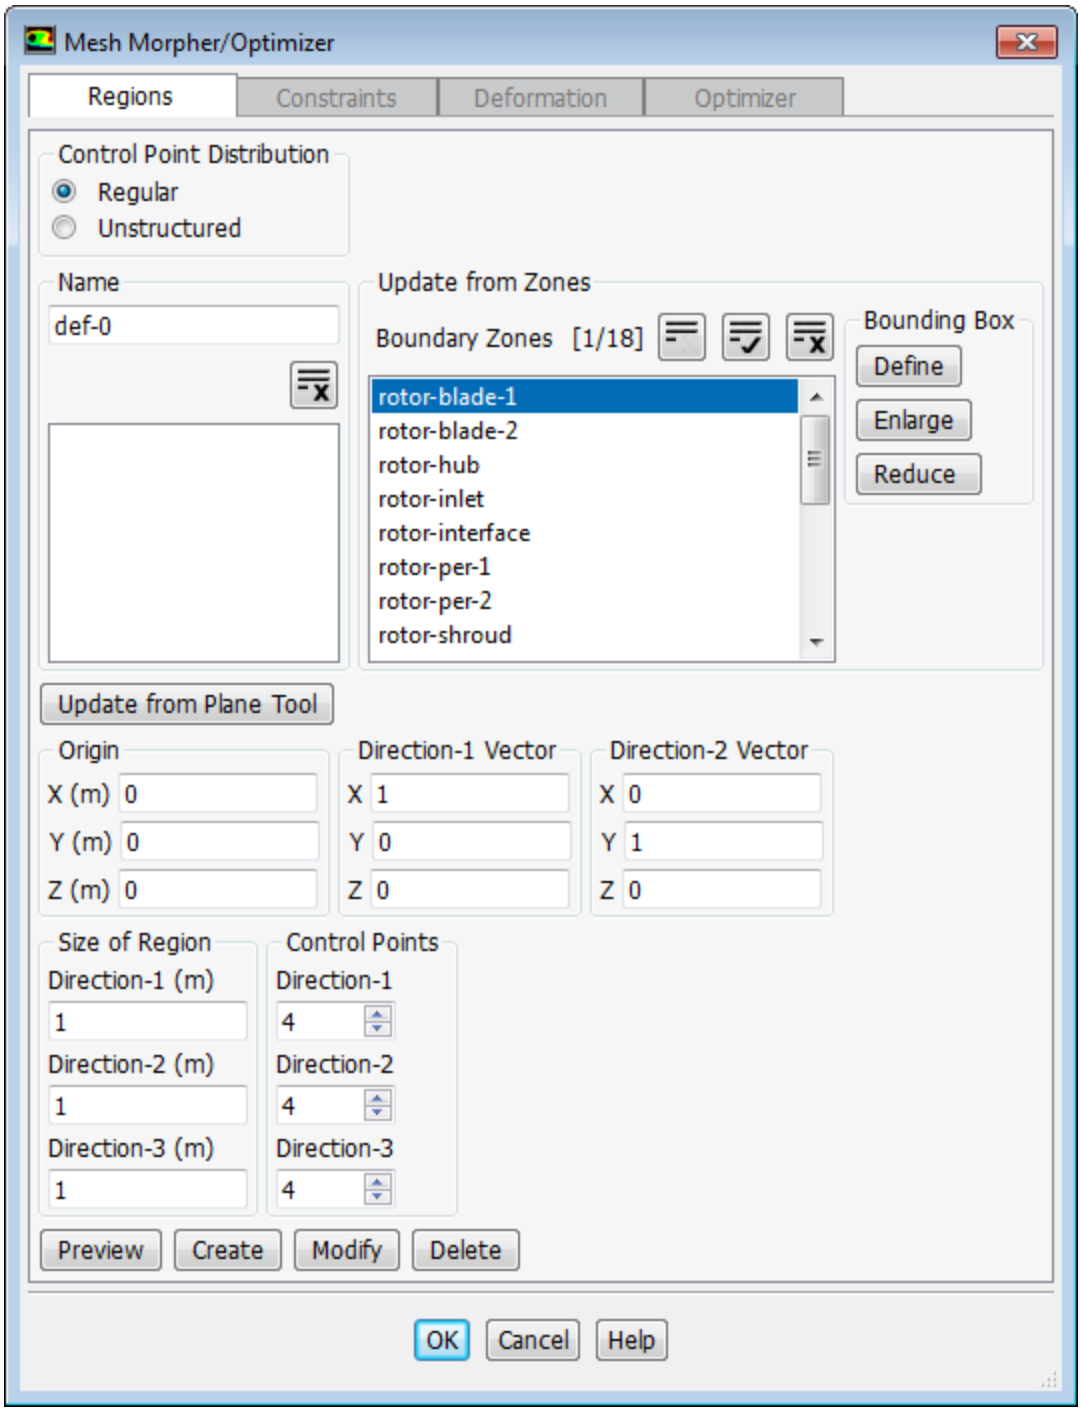
highlights the interface zones assigned to the mesh interface selected in the **Mesh Interfaces** group box, and allows you to select specific interface zones to be displayed in the graphics window using the **Draw** button.

38.2.52. Mesh Morpher/Optimizer Dialog Box

The **Mesh Morpher/Optimizer** dialog box allows you to use the mesh morpher/optimizer to deform the mesh in order to solve shape optimization problems. You can deform the mesh manually, allow a built-in optimizer to define the deformation in order to minimize an objective function, or use Design Exploration in ANSYS Workbench to easily explore a variety of deformation scenarios. See Using the Mesh Morpher/Optimizer (p. 2125) for further details.

Design → **Parameter-Based** → **Optimizer...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Regions

tab allows you to define the regions of the domain where the mesh will be deformed in order to optimize the shape.

Control Point Distribution

allows you to select the way in which you will define the locations of the control points, as well as the kinds of motions you can apply.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Regular
specifies that the control points will be spread in a regular distribution throughout the entire deformation region. The number of control points along each of the defining direction vectors will be specified in the **Control Points** group box. The motion of the control points will be limited to translations, as the ability to define rotational or radial motions will not be available.

Unstructured

specifies that control point locations will be specified by right-clicking with the mouse on boundary zones, distributing an approximate number throughout a zone, or by entering coordinates, using the Define Control Points Dialog Box (p. 2685). The motion of the control points will be able to be defined as translations, as rotations about a point / axis, or radially about a point / axis.

Name
provides controls for the deformation regions you are defining. The upper text-entry box defines the name of the region that is created when you click the **Create** button. The lower selection list allows you to select a region that has already been created, in order to display it in the graphics window, modify the settings via the **Modify** button, or delete the region via the **Delete** button.

Update from Zones
allows you to create a bounding box that defines the deformation region.

Boundary Zones
specifies the boundary zones that will be used to generate a bounding box for the deformation region when you click the **Define** button.

Define
updates the values in the **Origin**, **Direction-1 Vector**, **Direction-2 Vector**, and **Size of Region** group boxes based on a bounding box that encompasses the selections in the **Boundary Zones** list, and previews the bounding box in green in the graphics window.

Enlarge
increases the size of the bounding box created by the **Define** button, and previews the revised bounding box in green in the graphics window.

Reduce
decreases the size of the bounding box created by the **Define** button, and previews the revised bounding box in green in the graphics window.

Update from Plane Tool
updates the values in the **Direction-1 Vector** and **Direction-2 Vector** group boxes based on the settings in the plane tool. See Using the Plane Tool (p. 1724) for information about the plane tool. This button is only available for 3D cases.

Update from Line Tool
updates the values in the **Direction-1 Vector** and **Direction-2 Vector** group boxes based on the settings in the line tool. See Using the Line Tool (p. 1720) for information about the line tool. This button is only available for 2D cases.

Origin
allows you to define the Cartesian coordinates of the origin of the deformation region.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

X

defines the *x* coordinate of the origin of the deformation region.

Y

defines the *y* coordinate of the origin of the deformation region.

Z

defines the *z* coordinate of the origin of the deformation region. This number-entry box is only available for 3D cases.

Direction-1 Vector

allows you to define a vector that acts as the first direction of the deformation region relative to the **Origin**.

X

defines the *x* component of the first direction vector of the deformation region.

Y

defines the *y* component of the first direction vector of the deformation region.

Z

defines the *z* component of the first direction vector of the deformation region. This number-entry box is only available for 3D cases.

Direction-2 Vector

defines a vector that is used to calculate the second direction of the deformation region relative to the **Origin**. For 2D cases, the values in the **Direction-2 Vector** group box are automatically defined by ANSYS Fluent to be perpendicular to the **Direction-1 Vector**. For 3D cases, the vector defined by the **Direction-2 Vector** group box is projected onto a plane that intersects the **Origin** and is perpendicular to the vector defined in the **Direction-1 Vector** group box, in order to calculate the second direction.

X

defines the *x* component of the vector used to calculate the second direction of the deformation region. This number-entry box is only editable for 3D cases.

Y

defines the *y* component of the vector used to calculate the second direction of the deformation region. This number-entry box is only editable for 3D cases.

Z

defines the *z* component of the vector used to calculate the second direction of the deformation region. This number-entry box is only available for 3D cases.

Size of Region

allows you to define the overall dimensions of the deformation region.

Direction-1

defines the length of the deformation region along the direction specified by the **Direction-1 Vector** group box.

Direction-2

defines the length of the deformation region along the direction specified by the **Direction-2 Vector** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Direction-3
defines the length of the deformation region along the third axis (that is, the cross product of the vectors defined by the **Direction-1 Vector** and **Direction-2 Vector** group boxes). This number-entry box is only available for 3D cases.

Boundary Continuity
allows you to specify whether the mesh transitions are smooth or abrupt wherever the mesh intersects with the limits of the deformation region. This group box is only available when **Unstructured** is selected from the **Control Point Distribution** list.

Smooth Transitions
enables smooth mesh transitions wherever the mesh intersects with the limits of the deformation region, based on the creation of stationary control points at those intersections.

Display Control Points
displays the stationary control points created when the **Smooth Transitions** option is enabled.

Control Points
allows you to define the control points for the deformation regions.

Direction-1
defines the number of control points for the deformation region selected in the **Name** group box along the direction specified by the **Direction-1 Vector** group box. This number-entry box is only available when **Regular** is selected from the **Control Point Distribution** list.

Direction-2
defines the number of control points for the deformation region selected in the **Name** group box along the direction specified by the **Direction-2 Vector** group box. This number-entry box is only available when **Regular** is selected from the **Control Point Distribution** list.

Direction-3
defines the number of control points for the deformation region selected in the **Name** group box along the third axis (that is, the cross product of the vectors defined by the **Direction-1 Vector** and **Direction-2 Vector** group boxes). This number-entry box is only available for 3D cases when **Regular** is selected from the **Control Point Distribution** list.

Define...
opens the Define Control Points Dialog Box (p. 2685), which you can use to define the control points. This button is only available when **Unstructured** is selected from the **Control Point Distribution** list.

Preview
displays (in green) the bounding box that results from the current settings in the **Origin**, **Direction-1 Vector**, **Direction-2 Vector**, and **Size of Region** group boxes.

Create
creates a new deformation region with the name specified in the upper text-entry box of the **Name** group box and with the settings defined using the **Origin**, **Direction-1 Vector**, **Direction-2 Vector**, **Size of Region**, and (for regular control point distributions) **Control Points** group boxes. The newly created deformation region will be added to and selected in the lower **Name** selection list, and will be displayed (in blue) in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modify
modifies the saved settings for the deformation region selected in the lower **Name** selection list and displays the modified region in the graphics window.

Delete
deletes the deformation region selected in the lower **Name** selection list.

Constraints
tab allows you to define the constraints on the boundary zones, in order to limit the freedom of particular zones that fall within the deformation region(s) during the morphing of the mesh.

Zones
allows you to select the boundary zones for which you are defining a constraint.

Option
specifies the constraint on the boundary zones selected from the **Zones** list.

Unconstrained
specifies that the boundary zones are completely free to be deformed according to the assigned parameters.

Passive
specifies that the nodes of the boundary zones are partially constrained to varying degrees, based on their proximity to adjacent boundary zones that are fixed. The nodes in a passive boundary zone behave in a similar manner to the interior mesh nodes, in order to ensure that there is a smooth transition between fixed and unconstrained boundary zones.

Fixed
specifies that the boundary zones are fixed and will not be deformed.

Display
displays the selected **Zones** in the graphics window.

Summary
prints a list in the console that summarizes the constraint definitions for all of the boundary zones.

Deformation
tab allows you to define the deformation.

Number of Parameters
defines the number of parameters available to define the motion of the control points.

Parameter Values
allows you to define either the magnitude of deformation associated with each parameter (when you are manually specifying the deformation or using Design Exploration in ANSYS Workbench to explore multiple deformation scenarios) or the bounds for each parameter (when you are using a built-in optimizer).

par1, par2...
specify the magnitude of deformation associated with each parameter. You can enter a numeric value in the field or use the icon to create or assign an input parameter (see Select Input Parameter Dialog Box (p. 2384) for details). These fields and icons are only available when **none** or **workbench** is selected from the **Optimizer** drop-down list in the **Optimizer** tab. Note that the value entered here will specify a length in meters for translations and radial motions, and will

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specify an angle in degrees for rotations; these units will be used regardless of what units you are using in the case.

Apply
saves definitions for the parameter fields in the **Parameter Values** group box. This button is only available when **none** or **workbench** is selected from the **Optimizer** drop-down list in the **Optimizer** tab.

Set Bounds...
opens the Parameter Bounds Dialog Box (p. 2760), where you can define strict minimum and maximum values for the parameters. Note that this button is not available when **workbench** is selected from the **Optimizer** drop-down list in the **Optimizer** tab.

Motion Settings...
opens the Motion Settings Dialog Box (p. 2749), where you can define the motion of the control points.

Deform
applies the current settings in the **Parameter Values** group box, modifies the mesh, and updates the mesh display in the graphics window. This button is only available when **none** is selected from the **Optimizer** drop-down list in the **Optimizer** tab.

Check
displays a mesh check report in the console for the mesh displayed in the graphics window. This button is only available when **none** is selected from the **Optimizer** drop-down list in the **Optimizer** tab. The mesh check report provides volume statistics, mesh topology and periodic boundary information, verification of simplex counters, and verification of node position with reference to the x axis for axisymmetric cases, in the same manner as the **Check** button in the **General** task page (see Checking the Mesh (p. 192) for details).

Reset
undoes any modifications made to the mesh as a result of the **Deform** button and updates the mesh display in the graphics window.

Optimizer
tab allows you to define the settings for the optimizer.

Optimizer
specifies which optimizer is used. The choices include **none** (for manual deformation); **compass**, **newuoa**, **powell**, **rosenbrock**, **simplex**, and **torczon** (for optimization in ANSYS Fluent); and **workbench** (for optimizing using Design Exploration in ANSYS Workbench). Note that **workbench** is only available if you have launched your ANSYS Fluent session from ANSYS Workbench. For information about how the built-in optimizers function or how to use Design Exploration, see Design Analysis and Optimization in the User's Guide or Working With Input and Output Parameters in Workbench in the ANSYS Fluent in Workbench User's Guide, respectively.

Objective Function Definition...
opens the Objective Function Definition Dialog Box (p. 2757), where you can specify the format of the objective function that will be minimized during the optimization process. This button is not available if **none** or **workbench** is selected from the **Optimizer** drop-down list.

Optimizer Settings
allows you to specify the optimizer settings. This group box is not available if **none** or **workbench** is selected from the **Optimizer** drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum Number of Designs
defines the maximum number of design stages the optimizer will undergo to reach the specified objective function.

Maximum Iterations per Design
defines the maximum number of iterations ANSYS Fluent will perform for each design change.

Optimizer Convergence Criteria
defines the convergence criteria for the optimizer.

Initial Parameter Variation
defines how much the parameters will be allowed to vary during the initial calculations when **newuoa** is selected from the **Optimizer** drop-down list.

Mesh Quality
allows you to enable and define a mesh quality check: if the orthogonal quality (as defined in Mesh Quality (p. 131)) for any cell of a mesh is less than a specified value, no solution is calculated for the mesh and Fluent proceeds to the next design stage. This group box is not available if **none** is selected from the **Optimizer** drop-down list.

Reject Poor Quality Meshes
enables the consideration of orthogonal quality when determining whether a solution should be calculated for a mesh.

Minimum Orthogonal Quality
defines the minimum orthogonal quality value every cell must have in order for a solution to be calculated for a mesh. Values may range from `0`–`1` (where `0` represents the worst quality).

Case and Data File Sets
allows you to enable the automatic saving of intermediate case and data files at specified intervals during the optimization run, so that you can restart an interrupted solution in the same or a different Fluent session without increasing the overall number of design iterations needed to reach convergence. This group box is not available if **none** or **workbench** is selected from the **Optimizer** drop-down list.

Save Every
specifies the frequency (in number of design iterations) that you want intermediate case and data file sets saved. Note that the default value is **0**, which specifies that no intermediate files will be saved.

Maximum Number Retained
specifies the maximum number of intermediate case and data files sets you want to retain. After the maximum limit of file sets has been saved, ANSYS Fluent begins overwriting the earliest existing intermediate file set.

File Name
specifies a root name for the intermediate case and data file sets, which will be appended with a number that represents the design iteration during which it was saved. Note that you can include a folder path in the file name if you want the files saved outside of the working folder.

Initialization
provides settings that determine how the solution variables are treated after the mesh is deformed during the optimization process. This group box is not available if **none** or **workbench** is selected from the **Optimizer** drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Method
allows you to select one of the following:

Initialize Data After Morphing
specifies that the solution variables should be initialized to the values defined in the **Solution Initialization** task page after deformation.

Continue with Current Data
specifies that the solution variables should remain the values obtained in the previous design iteration.

Read Data File After Morphing
specifies that the solution variables are set to the values obtained from the data file specified in the **Data File Name** text-entry box after deformation. This selection is not available when **newuoa** is selected from the **Optimizer** drop-down list.

Data File Name
specifies the data file from which the solution variables are obtained when **Read Data File After Morphing** is selected.

Execute Commands
allows you to specify commands (text commands or command macros) that will be run during the optimization runs of the mesh morpher/optimizer. This group box is not available if **none**, **newuoa**, or **workbench** is selected from the **Optimizer** drop-down list.

Initial Commands
specifies the commands that will be run after the design has been modified, but before ANSYS Fluent has started to run the calculation for that design stage.

End Commands
specifies the commands that will be run after the solution has run and converged for a design stage.

Monitor...
opens the Optimization History Monitor Dialog Box (p. 2759), which allows you to plot and/or record how the value of the objective function varies with each design stage. This button is not available if **none**, **newuoa**, or **workbench** is selected from the **Optimizer** drop-down list.

Apply
saves the settings in the **Optimizer** tab.

Summary
displays a summary of the mesh morpher/optimizer settings in the console.

Optimize
initiates the optimization process using the settings saved in all of the tabs of the **Mesh Morpher/Optimizer** dialog box. This button is not available if **none** or **workbench** is selected from the **Optimizer** drop-down list.

38.2.53. MiniVAS Settings Dialog Box

The **MiniVAS Settings** dialog box allows you to set specific MiniVAS options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **MiniVAS Settings** dialog box is opened by clicking the **Settings...** button in the Video Control Dialog Box (p. 2833), after you have selected MiniVAS as your video device protocol.

Controls

VTR Identification

identifies the type of VTR the MiniVAS is connected to. The identification is a two-character code reserved for your VTR model (see your MiniVAS documentation for details). If left blank, this field is ignored and the MiniVAS will use the code that has been permanently stored in its ROM. It is recommended that you leave this field blank unless you know that a code change is required. If you open this dialog box after opening a connection to the MiniVAS, this field will contain the code that is stored in the MiniVAS.

VTR Video Format

identifies the video format standard to which your VTR conforms. This setting is used to determine the video frame rate (frames/sec).

NTSC

(National Television Standards Committee) is the main video format used in North America and Japan. The video frame rate is 30 frames/sec.

PAL

(Phase Alternate Line) is the video format used by some countries in Western Europe, Asia, and Australia. The video frame rate is 25 frames/sec.

VTR Tape Format

specifies which counter format to use for editing. MiniVAS provides commands based on both time code and frame code.

Time Code

instructs MiniVAS to control the VTR using time code.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Frame Code
instructs MiniVAS to control the VTR using frame code.

Preroll
specifies the preroll time in seconds. This is used when performing **Edit** records, including frame-by-frame animation recording, to make sure the tape is moving at the proper speed through the recorded segment. The value given is the number of seconds the tape will play up to the record in point. The default setting should be sufficient for most VTR devices.

Preblack Mode
specifies the mode used when you perform a preblack recording session.

Preblack
instructs the MiniVAS to perform a "hard" record on a previously unformatted tape. During this operation, the MiniVAS will command the VTR to write both a time code and a VIFC frame code to the tape.

Prestripe
instructs the MiniVAS to perform an "edit" record on a previously formatted tape that already has a time code. During this operation, the MiniVAS will command the VTR to write a VIFC frame code to the tape.

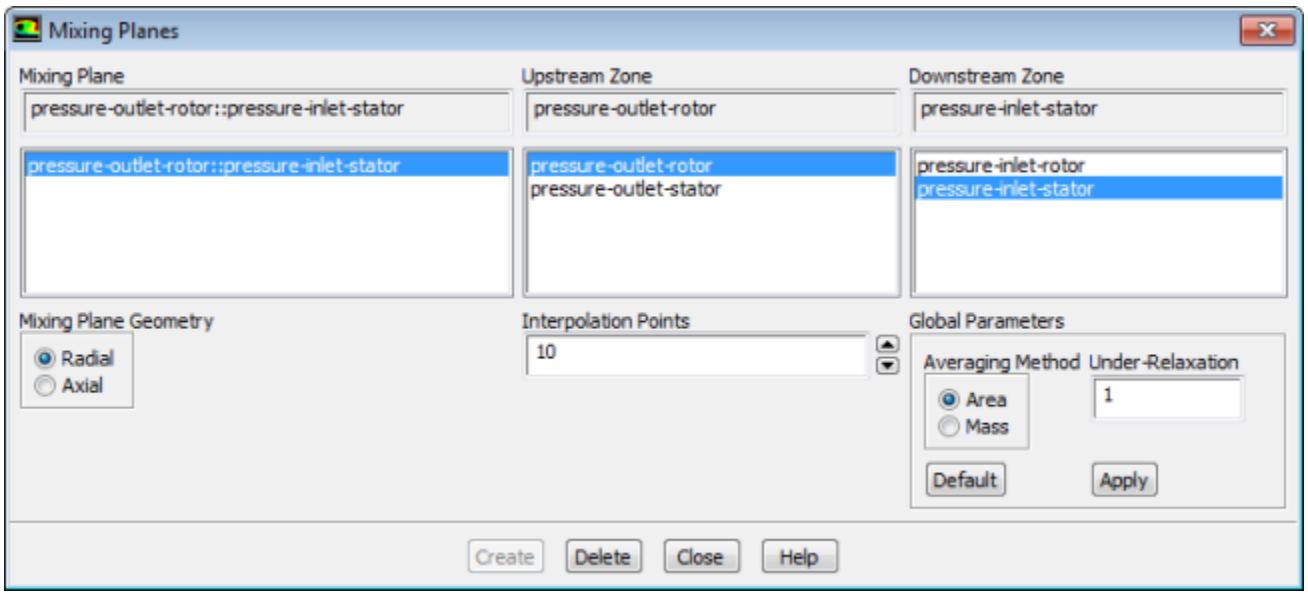
In either case, any previously recorded video will be destroyed.

Verbose Mode
enables the echoing of each MiniVAS command as it is sent to the MiniVAS controller.

38.2.54. Mixing Planes Dialog Box

The **Mixing Planes** dialog box allows you to define the mixing planes for a mixing plane model. See Setting Up the Mixing Plane Model (p. 619) for details about using the items below.

Setting Up Domain → Mesh Models → Mixing Planes...



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mixing Plane
contains a list from which you can select an existing mixing plane, and an informational field in which ANSYS Fluent displays the name of the currently selected (or most recently created) mixing plane.

Upstream Zone, Downstream Zone
contain lists from which you can select the boundaries on the upstream and downstream sides of the mixing plane, and informational fields that show the names of the zone you selected in each list. (You cannot edit these fields; the name in each field will be the name of the zone you selected in the list below it.)

Interpolation Points
specifies the number of radial or axial locations used in constructing the boundary profiles for circumferential averaging. This item appears only in 3D.

Mixing Plane Geometry
defines the geometry of the mixing plane interface. This item appears only in 3D.

Radial
specifies that information at the mixing plane interface is to be circumferentially averaged into profiles that vary in the radial direction, for example, $p(r)$, $T(r)$.

Axial
specifies that circumferentially averaged profiles are to be constructed that vary in the axial direction, for example, $p(x)$, $T(x)$.

Global Parameters
contains parameters related to the mixing plane calculation.

Averaging Method
consists of three profile averaging methods.

Area
is the default method and is expressed using Equation 2.17 in the Theory Guide.

Mass
provides better representation of the total quantities than the area averaging method. It is defined by Equation 2.18 of the Theory Guide.

Mixed-Out
is most representative of non-uniform flow profiles and is expressed using Equation 2.20 in the Theory Guide.

Under-Relaxation
specifies the under-relaxation factor for updating the boundary values at mixing planes.

Apply
sets the specified **Under-Relaxation**.

Default
sets the **Under-Relaxation** to its default value, as assigned by ANSYS Fluent. After execution, the **Default** button becomes the **Reset** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reset
resets the **Under-Relaxation** to its most recently saved value (that is, the value before **Default** was selected). After execution, the **Reset** button becomes the **Default** button.

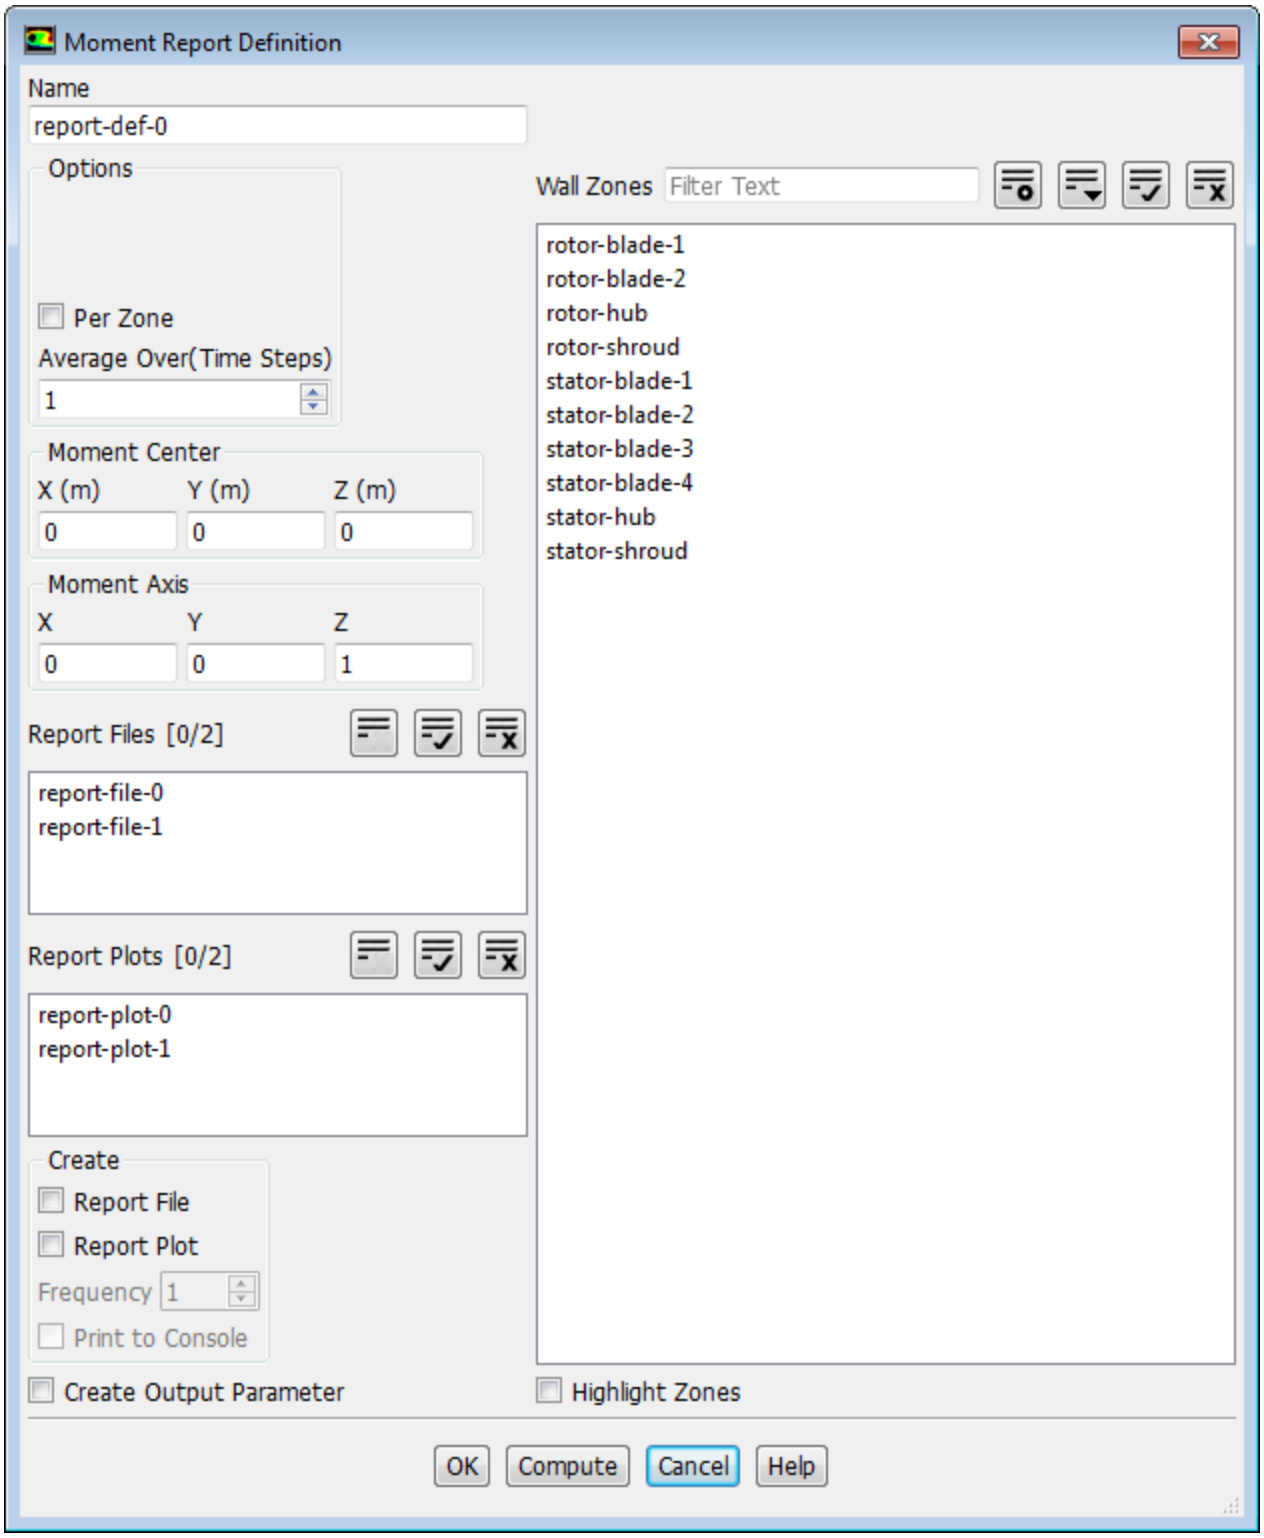
Create
creates the specified mixing plane (and assigns it a name in the **Mixing Plane** field).

Delete
deletes the mixing plane selected under **Mixing Plane**.

38.2.55. Moment Report Definition Dialog Box

Solving → **Reports** → **Definitions** → **New** → **Force Report** → **Moment...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Per Zone

specifies whether or not moments for multiple walls should be monitored on each wall separately.When this option is turned off (the default), Fluent computes and monitors the total force for all of the selected walls combined together.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Average Over (Time-Steps), Average Over (Iterations)
(optional) To have Fluent calculate a running average for the **Moment Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Moment Center
contains the Cartesian coordinates of the moment center.

Moment Axis
contains the Cartesian coordinates of the moment vector to be monitored.

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Wall Zones
lists the zones you can select for moment computation.

Highlight Zones
when enabled, highlights the selected **Wall Zones** in the graphics window.

OK
creates the report definition.

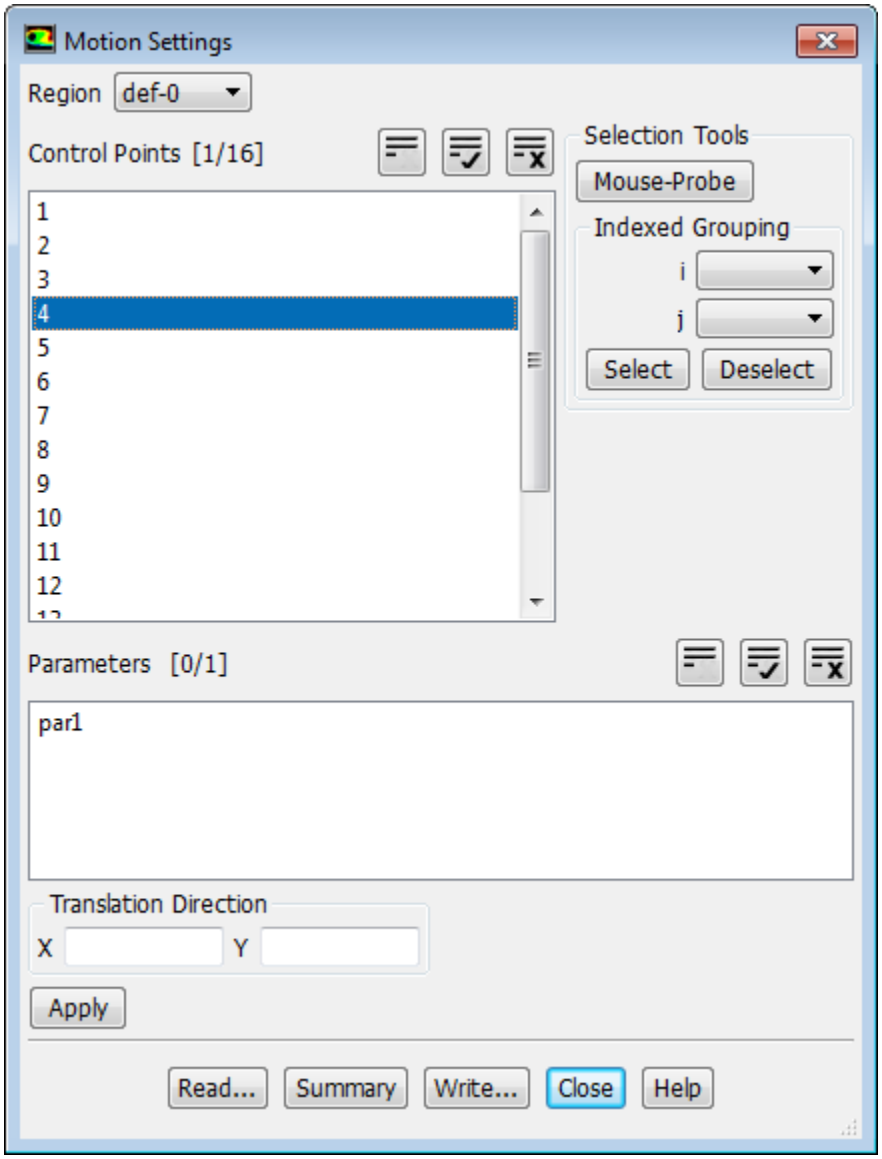
Compute
computes the value of the report definition at the selected zone(s) and prints to the console.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.56. Motion Settings Dialog Box

The **Motion Settings** dialog box allows you to define the motion of the control points, as part of the definition of the deformation produced by the mesh morpher/optimizer. Note that the controls and workflow of this dialog box are very much dependent on the selection in the **Control Point Distribution** list in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box. See Using the Mesh Morpher/Optimizer (p. 2125) for details about using this dialog box.

The **Motion Settings** dialog box is opened from the Mesh Morpher/Optimizer Dialog Box (p. 2734).



Controls (when **Regular** is selected from the **Control Point Distribution** list in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box)

Region

selects the deformation region for which you are assigning parameters and translation directions to control points.

Control Points

defines the control points to which you are assigning parameters and translation directions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selection Tools

provides tools for selecting the control points to which you are assigning parameters and translation directions.

Mouse-Probe

allows you to specify the **Control Points** by clicking in the graphics window with the mouse-probe button (which is the right mouse button, by default).

Indexed Grouping

allows you to select the control points based on their assigned indices.

i

allows you to select from a list of control point index numbers, which identify the location in a sequence (starting at the origin of the region) of control points along the direction-1 vector (as defined in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box).

j

allows you to select from a list of control point index numbers, which identify the location in a sequence (starting at the origin of the region) of control points along the direction-2 vector (as defined in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box).

k

allows you to select from a list of control point index numbers, which identify the location in a sequence (starting at the origin of the region) of control points along the direction-3 vector (as defined—though not displayed—in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box).

Select

adds the control points that satisfy the selected index criteria (that is, the selections from the **i**, **j**, and **k** drop-down lists) to the list of selected **Control Points**.

Deselect

removes the control points that satisfy the selected index criteria (that is, the selections from the **i**, **j**, and **k** drop-down lists) from the list of selected **Control Points**.

Parameters

specifies the names of the parameters (whose values are displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) that you are assigning to the **Control Points**. The products of the values associated with these parameters and the settings specified in the **Translation Direction** group box define the displacement of the control points during manual deformation.

Translation Direction

allows you to define coefficients in the *x*, *y*, and (for 3D cases) *z* directions to scale the magnitude of deformation for the selected parameters. If you use a built-in optimizer, these coefficients provide the direction of the displacement of the control points and the optimizer determines the overall magnitude of displacement. Alternatively, if you manually specify the deformation or use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, the values you enter in the **Translation Direction** group box are multiplied with the values of the **Parameters** (as displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) to define the displacement of the control points.

X

defines the scaling coefficient applied to the deformation parameter in the *x* direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Y
defines the scaling coefficient applied to the deformation parameter in the *y* direction.

Z
defines the scaling coefficient applied to the deformation parameter in the *z* direction. This number-entry box is only available for 3D cases.

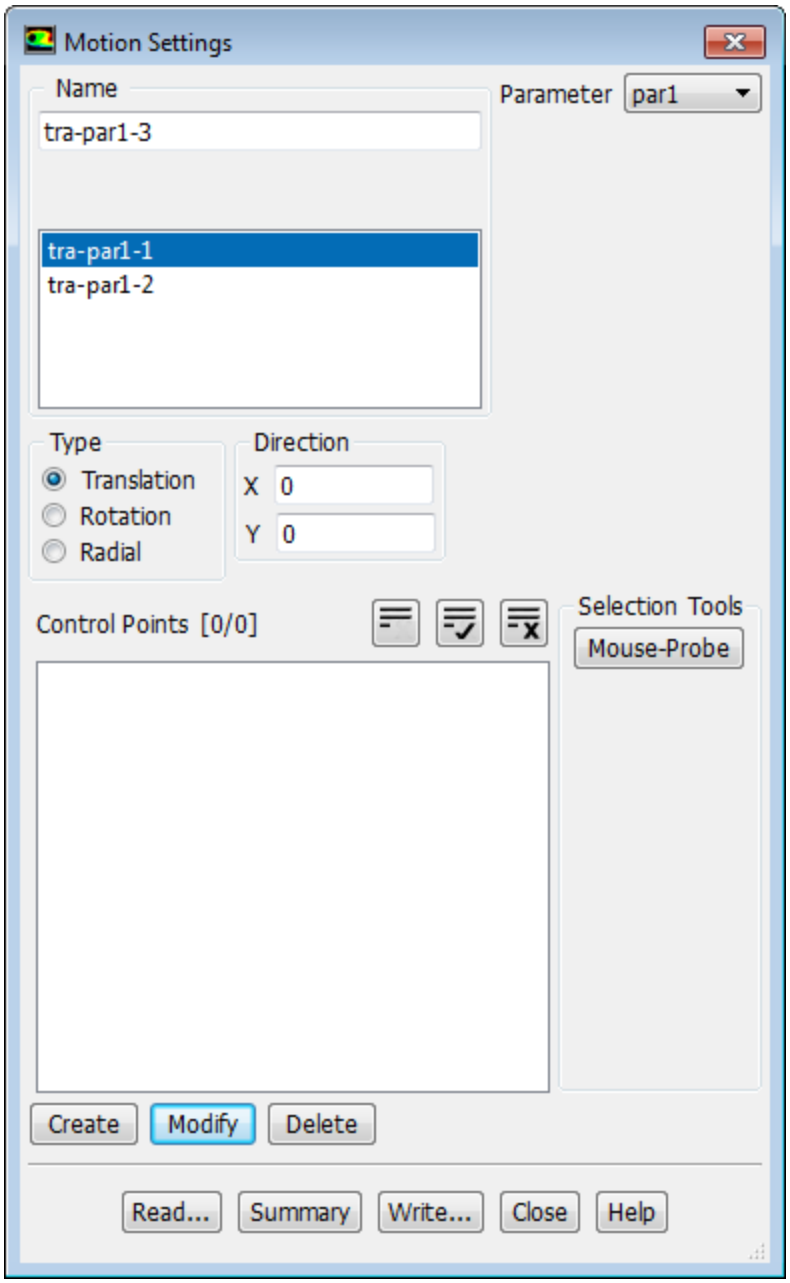
Apply
saves the selections made in the **Parameters** selection list and the values entered in the **Translation Direction** group box, and assigns these parameter settings to the control points selected in the **Control Points** selection list.

Read...
allows you to define your motion settings by reading an ASCII text file. See Mesh Morpher/Optimizer File Formats (p. 2867) for further details about the text file format.

Summary
displays a summary of the saved motion settings in the console.

Write...
allows you to write your saved motion settings to an ASCII text file. See Mesh Morpher/Optimizer File Formats (p. 2867) for further details about the text file format.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls (when **Unstructured** is selected from the **Control Point Distribution** list in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box)

Name

provides controls for the motions you are defining. The upper text-entry box defines the name of the motion that is created when you click the **Create** button (which by default is based on the type of motion and the related parameter). The lower selection list allows you to select a motion that has already been created, in order to display the selections associated with it, or to modify or delete the motion using the **Modify** or **Delete** buttons, respectively.

Parameter

allows you to select the parameter (whose value is displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) for the motion.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Type
allows you to specify the type of motion you want to define.

Translation
specifies that the motion is a translation, based on the settings in the **Direction** group box.

Rotation
specifies that the motion is a rotation about a point (for 2D) or an axis (for 3D), based on the settings in the **Axis Origin** group box and (for 3D cases) **Axis Direction** group box.

Radial
specifies that the motion is defined radially about a point (for 2D) or an axis (for 3D), based on the settings in the **Axis Origin** group box and (for 3D cases) **Axis Direction** group box.

Direction
allows you to define coefficients in the **X**, **Y**, and (for 3D cases) **Z** directions to scale the magnitude of deformation for the selected parameter. If you use a built-in optimizer, these coefficients provide the direction of the displacement of the control points and the optimizer determines the overall magnitude of displacement. Alternatively, if you manually specify the deformation or use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, the values you enter in the **Direction** group box are multiplied with the values of the **Parameter** (as displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) to define the displacement of the control points.

This group box is only available when **Translation** is selected from the **Type** list.

Axis Direction
allows you to define the **X**, **Y**, and **Z** components of the vector about which the control points will rotate or move radially, when the selection in the **Type** list is **Rotation** or **Radial**, respectively. This group box is only available for 3D cases.

Axis Origin
allows you to define the **X**, **Y**, and (for 3D cases) **Z** coordinates of the origin about which the control points will rotate or move radially, when the selection in the **Type** list is **Rotation** or **Radial**, respectively.

Control Points
allows you to select the control points that will undergo the motion.

Selection Tools
provides tools for selecting the control points that will undergo the motion.

Mouse-Probe
allows you to specify the **Control Points** by clicking in the graphics window with the mouse-probe button (which is the right mouse button, by default).

Create
creates a new motion based on the currently displayed settings.

Modify
modifies the saved settings for the motion selected in the lower **Name** selection list.

Delete
deletes the motion selected in the lower **Name** selection list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Read...
allows you to define your motion definitions by reading an ASCII text file. See Mesh Morpher/Optimizer File Formats (p. 2867) for further details about the text file format.

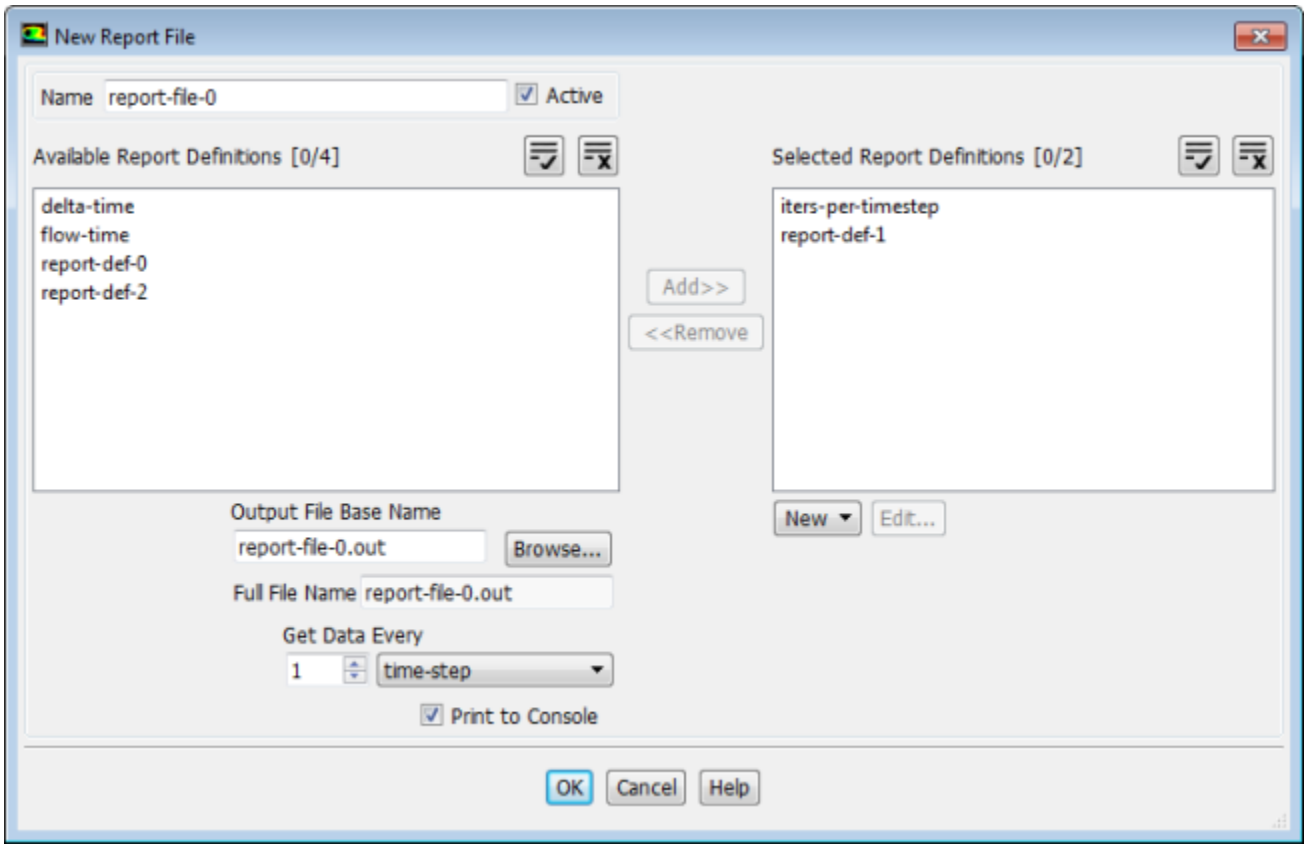
Summary
displays a summary of the saved motion definitions in the console.

Write...
allows you to write your saved motion definitions to an ASCII text file. See Mesh Morpher/Optimizer File Formats (p. 2867) for further details about the text file format.

38.2.57. New Report File Dialog Box

Solving → Reports → File...

Click **New...** in the **Report File Definitions** dialog box to open the **New Report File** dialog box.



Controls

Name
editable field displaying the name of the report file.

Active
check box (enabled by default) that determines if the file is written during the solution calculation.

Available Report Definitions
lists all of the existing report definitions not currently part of this report file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Add>>
moves the selected report definition(s) to the **Selected Report Definitions** list.

<<Remove
moves the selected report definition(s) to the **Available Report Definitions** list.

Output File Base Name
allows you to specify the name used when the file is saved.

Browse...
opens the **Select File** dialog box, allowing you to specify the location where the report file will be saved.

Full File Name
displays the name and location of the report file once it has been saved.

Get Data Every
indicates the frequency that the report definition data is written to the file. The default value of 1 allows you to write to the file at every iteration or time-step. Time-step is only a valid choice you are calculating unsteady flow.

Print to Console
indicates whether or not the contents of the report file are printed to the console at the frequency specified in the **Get Data Every** field.

Selected Report Definitions
lists all of the existing report definitions currently included in this report file.

New
drop-down list allowing you to create new report definitions (surface, volume, force, flux, dpm, and user-defined).

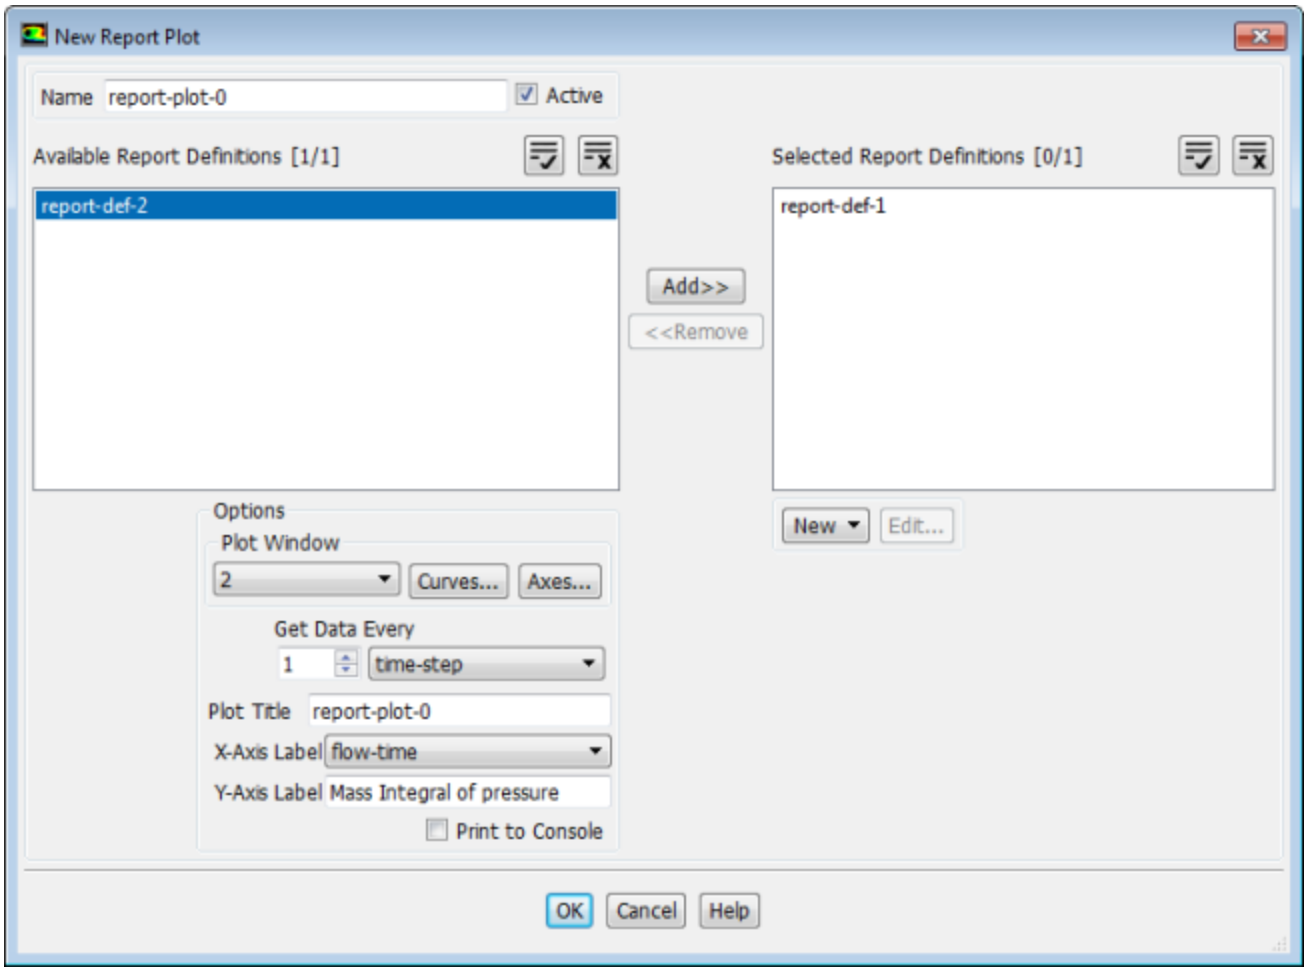
Edit...
allows you to modify the highlighted report definition in the **Selected Report Definition** list.

38.2.58. New Report Plot Dialog Box

Solving → Reports → Plot...

Click **New...** in the **Report Plot Definitions** dialog box to open the **New Report Plot** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Name
editable field displaying the name of the report plot.

Active
check box (enabled by default) that determines if the plot is plotted during the solution calculation.

Available Report Definitions
lists all of the existing report definitions not currently part of this report plot.

Add>>
moves the selected report definition(s) to the **Selected Report Definitions** list.

<<Remove
moves the selected report definition(s) to the **Available Report Definitions** list.

Options

Plot Window
allows you to specify the graphics window for this report plot.

Curves...
opens the Curves Dialog Box (p. 2610).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Axes...
opens the Axes Dialog Box (p. 2608).

Get Data Every
indicates the frequency that the report definition data is plotted in the graphics window. The default value of 1 allows you to plot the data at every iteration or time-step. Time-step is only a valid choice you are calculating unsteady flow.

Plot Title
provide a title for the plot.

X-Axis Label
choose whether the X-axis is flow-time or time-step.

Y-Axis Label
enter a label for the Y-axis.

Print to Console
indicates whether or not the contents of the report plot are printed to the console at the frequency specified in the **Get Data Every** field.

Selected Report Definitions
lists all of the existing report definitions currently included in this report plot.

New
drop-down list allowing you to create new report definitions (surface, volume, force, flux, dpm, and user-defined).

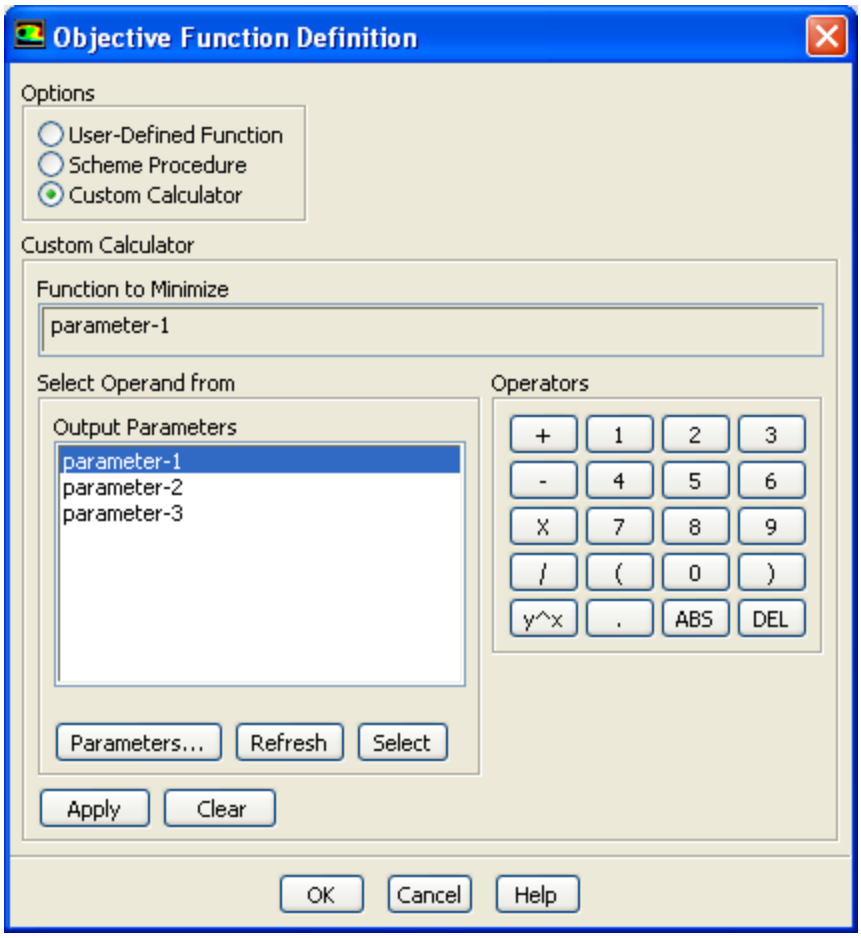
Edit...
allows you to modify the highlighted report definition in the **Selected Report Definition** list.

38.2.59. Objective Function Definition Dialog Box

The **Objective Function Definition** dialog box allows you to specify the format of the objective function that will be minimized by the mesh morpher/optimizer and (when it is a customized function of output parameters) to define the objective function. See Using the Mesh Morpher/Optimizer (p. 2125) for details about using this dialog box.

The **Objective Function Definition** dialog box is opened from the Mesh Morpher/Optimizer Dialog Box (p. 2734).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains options for the format of the objective function.

User-Defined Function
specifies that the objective function is provided via a user-defined function.

Scheme Procedure
specifies that the objective function is provided via a Scheme source file. This option is not available if **newuoa** is selected from the **Optimizer** drop-down list in the **Optimizer** tab of the **Mesh Morpher/Optimizer** dialog box.

Custom Calculator
specifies that the objective function is based on output parameters, and is defined by the controls in the **Custom Calculator** group box. This option is not available if **newuoa** is selected from the **Optimizer** drop-down list in the **Optimizer** tab of the **Mesh Morpher/Optimizer** dialog box.

Custom Calculator
allows you to define the objective function. This group box is only available when **Custom Calculator** is selected from the **Options** list.

Function to Minimize
displays the objective function defined by the controls in the **Custom Calculator** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select Operand from
allows you to include output parameters in the definition of the objective function.

Output Parameters
provides a list of available output parameters, which can be included in the definition of the objective function.

Parameters...
opens the Parameters Dialog Box (p. 2627), which you can use to create additional output parameters.

Refresh
updates the **Output Parameters** list, so that all available output parameters are displayed.

Select
enters the output parameter that is currently selected in the **Output Parameters** list in the **Function to Minimize** field.

Operators
allows you to include calculator operators in the definition of the objective function. Clicking a button in this group box causes the appropriate symbol to appear in the **Function to Minimize** field.

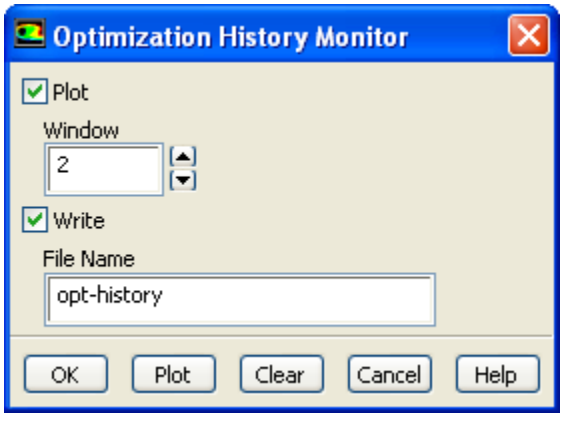
Apply
saves the custom objective function (displayed in the **Function to Minimize** field) as part of the case file.

Clear
deletes all of the text in the **Function to Minimize** field.

38.2.60. Optimization History Monitor Dialog Box

The **Optimization History Monitor** dialog box allows you to plot and/or record optimization history data, that is, how the value of the objective function (defined using the Mesh Morpher/Optimizer Dialog Box (p. 2734)) varies with each design stage produced by the mesh morpher/optimizer. See Using the Mesh Morpher/Optimizer (p. 2125) for details about using this dialog box.

The **Optimization History Monitor** dialog box is opened from the Mesh Morpher/Optimizer Dialog Box (p. 2734).



Controls

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plot
enables the plotting of the optimization history data in the graphics window (with the ID specified in **Window**).

Window
sets the ID of the graphics window in which the plot will be displayed. This number-entry box is only available when the **Plot** option is enabled. While ANSYS Fluent is iterating, the active graphics window is temporarily set to this ID to update the optimization history plot, and then it is returned to its previous value. Thus, the optimization history plot can be maintained in a separate window that does not interfere with other graphical postprocessing.

Write
enables the saving of the optimization history data to a file (with the name specified in **File Name**).

File Name
specifies the name of the file to which the optimization history data is written. This text-entry box is only available when the **Write** option is enabled.

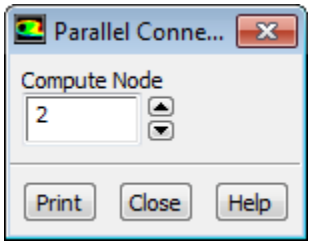
Plot
displays an XY plot of the optimization history data generated during the last calculation. Note that no plot will be displayed if the data was discarded using the **Clear** button.

Clear
discards the optimization history data, including the associated files. Each of these actions must be confirmed in a Question Dialog Box (p. 18).

38.2.61. Parallel Connectivity Dialog Box

The **Parallel Connectivity** dialog box prints the connectivity of the selected compute node. See Checking Network Connectivity (p. 2059) for details.

Parallel → Network → Connectivity...



Controls

Compute Node
indicates the compute node ID for which connectivity information is desired.

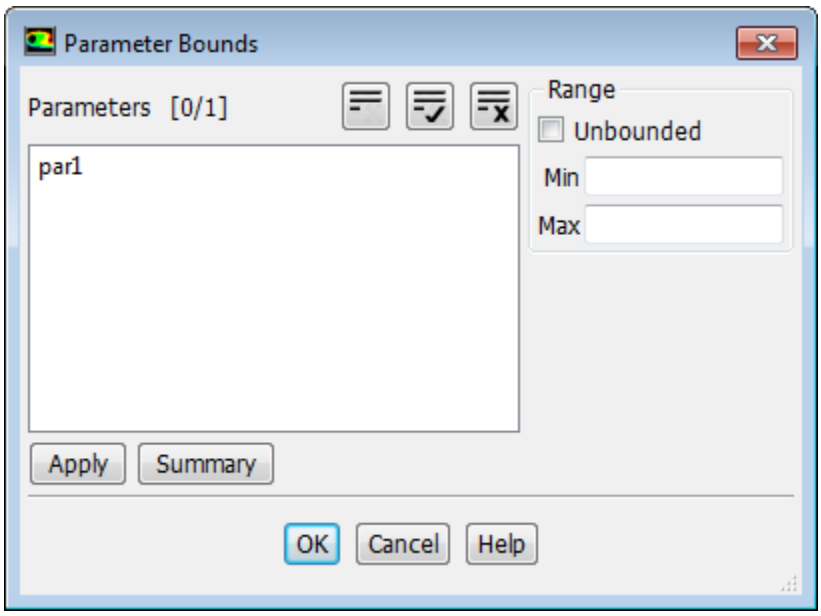
Print
prints information (in the console window) about the network connectivity for the selected compute node.

38.2.62. Parameter Bounds Dialog Box

The **Parameter Bounds** dialog box allows you to limit how much each parameter is allowed to deform when using the mesh morpher/optimizer. See Using the Mesh Morpher/Optimizer (p. 2125) for details about using this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Parameter Bounds** dialog box is opened from the Mesh Morpher/Optimizer Dialog Box (p. 2734).



Controls

Parameters
selects the parameters (created using the **Deformation** tab of the Mesh Morpher/Optimizer Dialog Box (p. 2734)) for which you are defining bounds.

Range
allows you to specify the bounds.

Unbounded
allows you to specify whether the selected **Parameters** are unbounded.

Min, Max
allows you to set the minimum and maximum values allowed for the selected **Parameters** when the **Unbounded** option is disabled.

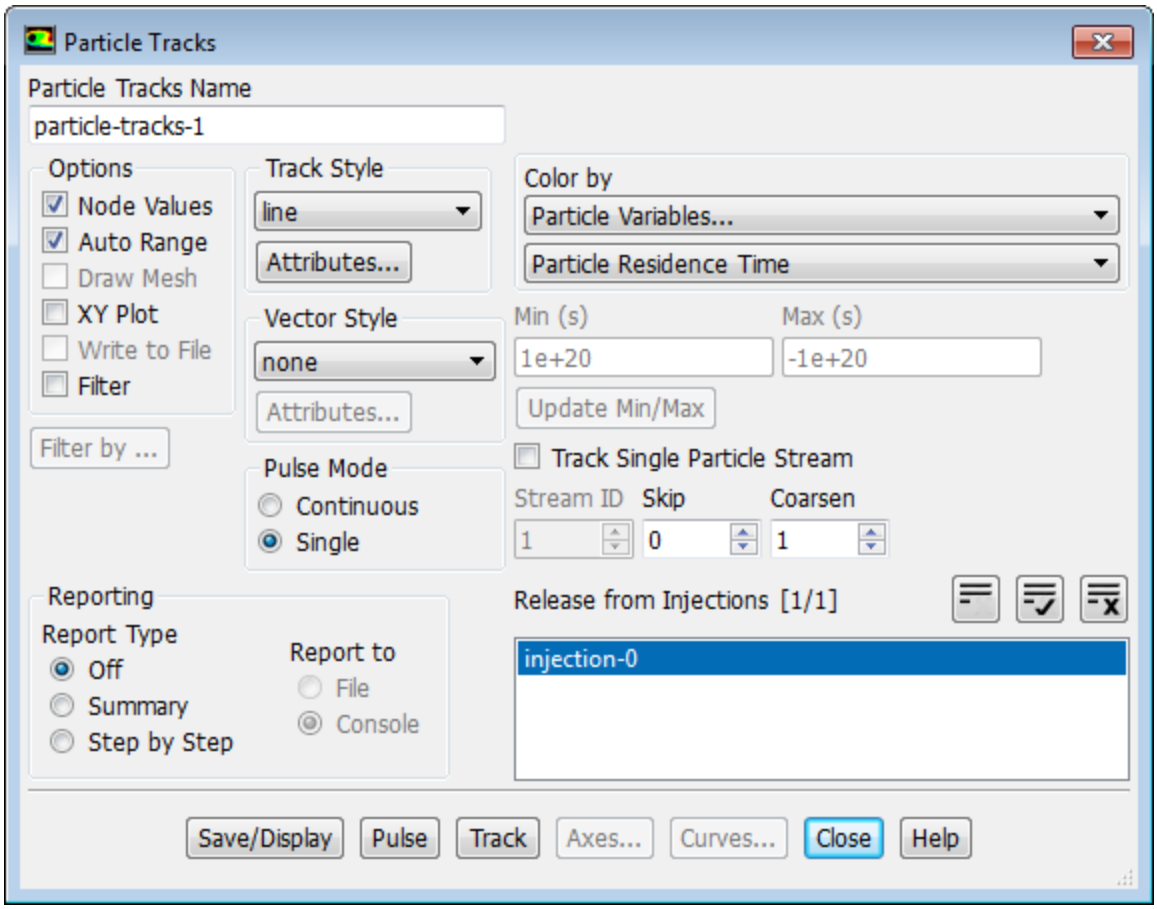
Apply
saves the bounds for the currently selected **Parameters**.

Summary
displays a summary of all of the saved parameter bounds in the console.

38.2.63. Particle Tracks Dialog Box

The **Particle Tracks** dialog box controls the generation and display of discrete phase particles. See Displaying of Trajectories (p. 1330) for details about the items below.

Postprocessing → Graphics → Particle Tracks → New...



Controls

Particle Tracks Name

is the name for a particle tracks definition. You can specify a name or use the default name **`particle-tracks-`*`id`***. This control appears only for particle tracks definitions.

Options

contains the options described below:

Node Values

specifies that node values should be interpolated to compute the scalar field at a particle location. This option is turned on by default. See Choosing Node or Cell Values (p. 1780) for details.

Auto Range

specifies that the minimum and maximum values of the scalar field will be the limits of that field. If this option is not selected, you can enter **Min** and **Max** values manually. These values determine the range of the color scale.

Draw Mesh

toggles between displaying and not displaying the mesh. The Mesh Display Dialog Box (p. 2163) is opened when **Draw Mesh** is selected.

XY Plot

enables the display of an XY plot along the particle trajectories. When this option is selected, the **Display** push button will change to **Plot**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Write to File
(available only when **XY Plot** is on) activates the file-writing option. When this option is selected, the **Plot** push button will change to **Write...**. Clicking on the **Write...** button will open The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the XY plot data. The format of this file is described in XY Plot File Format (p. 1850).

Enable Filter
when activated allows you to click the **Filter by...**.

Filter by...
opens the Particle Filter Attributes (p. 2561) where you can specify how you would like to filter the particles being displayed.

Reporting
allows you to specify how you would like to report particle tracks.

Report Type
controls the type of trajectory-fate reports to be displayed.

Off
disables reporting of trajectory fates.

Summary
enables summary reports of trajectory fates. See Reporting of Trajectory Fates (p. 1340) for details.

Step by Step
enables the step-by-step reporting of trajectories. This item will not appear if you have requested unsteady tracking in the Discrete Phase Model Dialog Box (p. 2278). See Step-by-Step Reporting of Trajectories (p. 1347) for details.

Current Positions
enables the reporting of the positions and velocities of all particles that are in the domain at the current time. This item appears only when unsteady tracking has been requested in the Discrete Phase Model Dialog Box (p. 2278). See Reporting of Current Positions for Unsteady Tracking (p. 1349) for details.

Report to
indicates the destination of the trajectory report.

File
enables the writing of the trajectory report to a file. When this option is enabled, the **Track** button will become the **Write...** button.

Console
enables the display of the trajectory report information in the console window.

Significant Figures
controls the number of significant figures used when a **Step by Step** or **Current Positions** report is selected.

Reporting Variables...
opens the Reporting Variables Dialog Box (p. 2562) that contains a list from which you can select the scalar field to be used to color the particle tracks.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Track Style
sets the trajectory style. Trajectories can be displayed as lines, ribbons, spheres, cylinders, or a set of points. Pulsing can be done only on **point** or **line** styles.

Attributes...
opens the Track Style Attributes Dialog Box (p. 2562), Particle Sphere Style Attributes Dialog Box (p. 2563), or the Ribbon Attributes Dialog Box (p. 2560), depending on the selected **Track Style**. These dialog boxes allow you to set the attributes for the chosen trajectory style.

Vector Style
sets the trajectory vector style. You can display the trajectories vectors in three different ways: **vector**, **centered-vector**, and **centered-cylinder**. All three styles are demonstrated in Controlling the Vector Style of Particle Tracks (p. 1334).

Attributes...
opens the Particle Vector Style Attributes Dialog Box (p. 2564).

Pulse Mode
specifies either a single or continuous release of particles that follow the trajectories, starting at the release surface, when you use the **Pulse** button to animate the trajectories.

Continuous
sets the pulse mode to continuously release particles from the initial positions.

Single
sets the pulse mode to release a single wave of particles.

The **Pulse Mode** is used only when particles are being **Pulsed**.

Y Axis Function
contains a list of solution variables that can be used for the y axis of the plot.

This item appears when the **XY Plot** option is turned on.

X Axis Function
contains a list of functions for the X-axis of the plot. You can plot the quantity selected in the **Y Axis Function** drop-down list as a function of the **Time** elapsed along the trajectory, or the **Path Length** along the trajectory.

This item appears when the **XY Plot** option is turned on.

Min/Max
display the values to which the lower and upper ends of the color scale map. If you are using the **Auto Range** option, these values will be automatically computed when you click **Compute**. If you are not using **Auto Range**, you can enter values manually.

Update Min/Max
computes the **Min** and **Max** for the field chosen in **Color by**.

Track PDF Transport Particles
enables the tracking of PDF transport particles. This item is available only when the composition PDF transport model is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Free Stream Particles
enables the tracking of free stream particles. Note that this option is available only when the Lagrangian wallfilm model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.

Wall Film Particles
enables the tracking of wall film particles. Note that this option is available only when the Lagrangian wallfilm model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.

Track Single Particle Stream
enables the tracking of a single particle stream in the selected injection, instead of all the streams in that injection. See Specifying Particles for Display (p. 1332) for details.

Stream ID
specifies the particle stream to be tracked when the **Track Single Particle Stream** option is enabled.

Skip
allows you to "thin" or "sample" the particles that are displayed.

Coarsen
reduces the plotting time by reducing the number of points that are plotted for a given trajectory in any cell. This is valid only for steady-state cases.

Release from Injections
selects the injections from which to release particles. You must select at least one injection before any particles can be released.

Display
displays the trajectories and generates a trajectory report in the console window (if requested).

Save/Display
displays the particle tracks in the active graphics window and saves the particle track definition. This button appears only for particle track definitions and replaces the **Display** button.

Plot
displays an XY plot along the particle trajectories. This button replaces the **Display** button when the **XY Plot** option is turned on.

Write...
opens The Select File Dialog Box (p. 19), in which you can save the XY plot data or trajectory report to a file. This button replaces the **Plot** button when the **Write to File** option is turned on, or the **Track** button when the **File** option is selected under **Report to**.

Pulse
animates the position of particles. If **Pulse Mode** is set to **Continuous**, particles are reintroduced at the seed positions repeatedly. If the mode is **Single**, a single wave of particles moves through the domain.

The label of this button changes to **Stop !** when the animation is in progress. Click **Stop !** to stop pulsing (and the label goes back to **Pulse**).

Track
computes the particle trajectories and generates any reports without displaying the trajectories in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

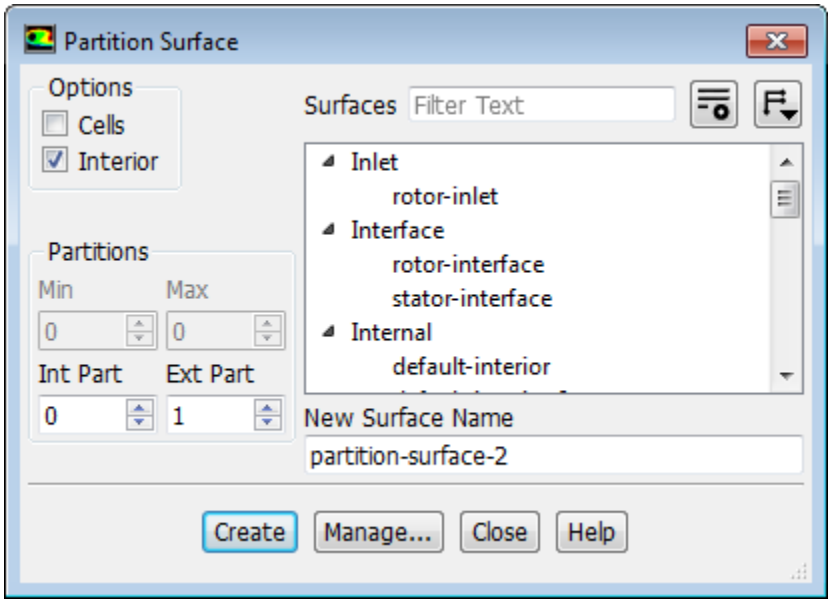
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the XY plot axes. This item appears when the **XY Plot** option is turned on.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot. This item appears when the **XY Plot** option is turned on.

38.2.64. Partition Surface Dialog Box

The **Partition Surface** dialog box allows you to create a surface defined by the boundary of two adjacent mesh partitions. See Partition Surfaces (p. 1712) for details about the items below.

Setting Up Domain → Surface → Create → Partition...



Controls

Options
contains check buttons that allow you to choose interior or exterior faces or cells to be contained in the partition surface.

Cells
specifies, when enabled, that the partition surface will consist of cells (either interior or exterior, depending on the status of the **Interior** check button) that lie on the partition boundary. When this option is disabled, the faces on the boundary between partitions will make up the partition surface. Depending on the status of the **Interior** check button, the faces will reflect data values for the interior or exterior cells.

Interior
toggles between interior and exterior cells. If the partition surface consists of faces instead of cells, **Interior** specifies for which cells data will be displayed on the faces. When this option is enabled, interior cells (cells that are on the **Int Part** side of the partition boundary) will make up the partition surface. When it is disabled, the partition surface will consist of exterior cells (cells that are on the **Ext Part** side of the partition boundary).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Partitions
contains information about which partitions are under consideration. The boundary that defines the partition surface is the boundary between the **Int Part** and the **Ext Part**. If there are more than two mesh partitions, each interior partition will share boundaries with several exterior partitions. By setting the appropriate values for **Int Part** and **Ext Part**, you can create surfaces for any of these boundaries.

Min/Max
indicates the minimum and maximum ID numbers of the mesh partitions. The minimum is always zero, and the maximum is one less than the number of processors.

Int Part
indicates the ID number of the interior partition (that is, the partition under consideration).

Ext Part
indicates the ID number of the bordering partition.

Surfaces
displays an informational list of existing surfaces.

New Surface Name
designates the name of the new surface. The default is the concatenation of the surface type and an integer which is the new surface ID.

Create
creates the surface.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

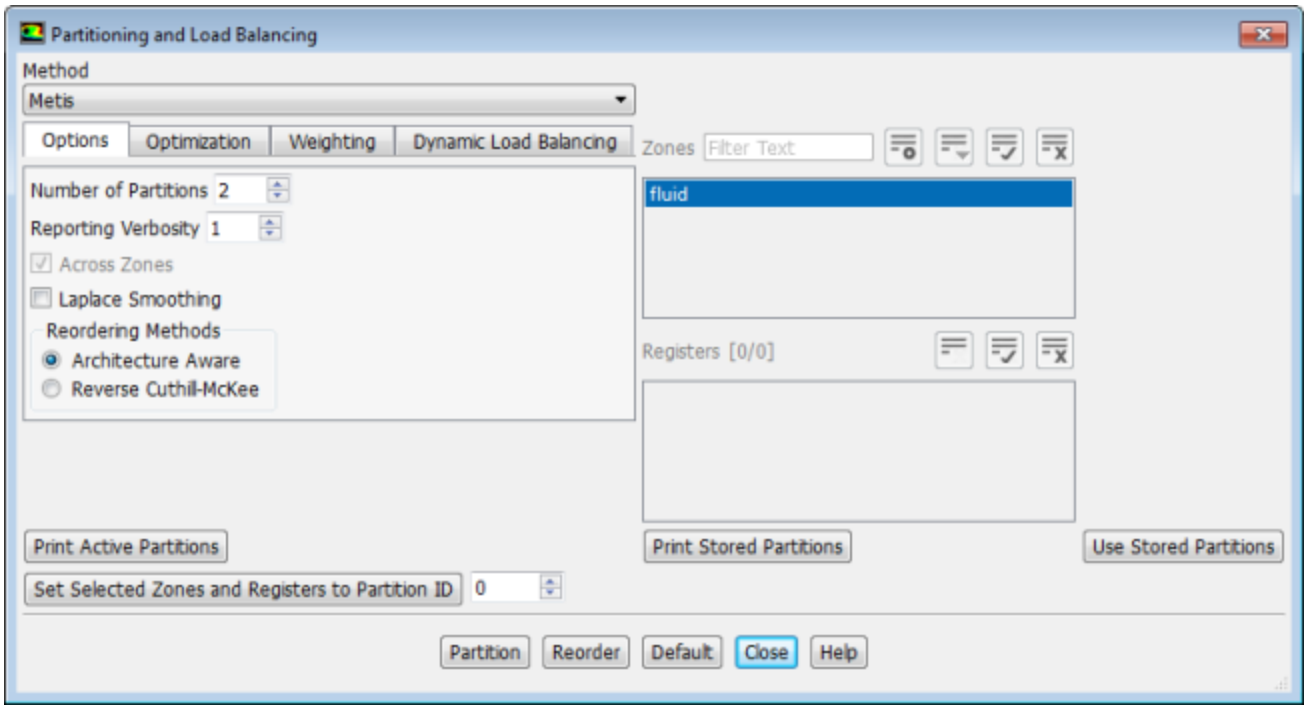
38.2.65. Partitioning and Load Balancing Dialog Box

The **Partitioning and Load Balancing** dialog box allows you to partition the mesh into separate clusters of cells for separate processors on a parallel computer. Note that the **Partitioning and Load Balancing** dialog box is slightly different in the serial and parallel solvers. See Partitioning the Mesh Manually and Balancing the Load (p. 2033) for details.

The **Partitioning and Load Balancing** dialog box also allows you to enable and control ANSYS Fluent's load balancing feature. Load balancing will automatically detect and analyze parallel performance, and redistribute cells between the existing compute nodes to optimize it. See Load Balancing (p. 2044) for more information about load balancing.

Parallel → General → Partitioning/Load Balancing...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Method

contains a drop-down list of the recursive partition methods that can be used to create the mesh partitions. The choices include the **Cartesian Axes**, **Cartesian Strip**, **Cartesian X-Coordinate**, **Cartesian Y-Coordinate**, **Cartesian Z-Coordinate**, **Cartesian R Axes**, **Cartesian RX-Coordinate**, **Cartesian RY-Coordinate**, **Cartesian RZ-Coordinate**, **Cylindrical Axes**, **Cylindrical R-Coordinate**, **Cylindrical Theta-Coordinate**, **Cylindrical Z-Coordinate**, **Metis**, **Polar Axes**, **Polar R-Coordinate**, **Polar Theta-Coordinate**, **Principal Axes**, **Principal Strip**, **Principal X-Coordinate**, **Principal Y-Coordinate**, **Principal Z-Coordinate**, **Spherical Axes**, **Spherical Rho-Coordinate**, **Spherical Theta-Coordinate**, and **Spherical Phi-Coordinate** techniques, which are described in Mesh Partitioning Methods (p. 2046).

Options

tab

Number of Partitions

defines the desired number of mesh partitions. This usually matches the number of processors available for parallel computing.

Reporting Verbosity

specifies the amount of information to be reported in the text (console) window during the partitioning. With the default value of 1, Fluent will print the number of partitions created, the number of bisections performed, the time required for the partitioning, and the minimum and maximum cell, face, interface, and face-ratio variations. (See Interpreting Partition Statistics (p. 2052) for details.) If you increase the **Reporting Verbosity** to 2, the partition method used, the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each partition will also be printed in the console window. If you decrease the **Reporting Verbosity** to 0, only the number of partitions created and the time required for the partitioning will be reported.

Across Zones

allows partitions to cross zone boundaries (the default). If turned off, it will restrict partitioning to within each cell zone. This is recommended *only* when cells in different zones require significantly

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

different amounts of computation during the solution phase, for example if the domain contains both solid and fluid zones.

Laplace Smoothing
enables the Laplace smoothing method, which can be used to prevent partition boundaries from lying along regions of high-aspect ratio cells. This can improve convergence behavior in cases with highly stretched cells.

Cutoff Aspect Ratio
controls the threshold for the Laplace smoothing method.

Reordering Method
is used to optimize parallel performance

Architecture Aware
is the default option and it accounts for the system architecture and network topology in remapping the partitions to the processors.

Reverse Cuthill-McKee
minimizes the bandwidth of the compute-node connectivity matrix (the maximum distance between two connected processes) without incorporating the system architecture.

Optimization
tab contains options for enabling schemes to optimize the partitions created by the selected partition method. In addition, the optimization scheme will be applied until appropriate criteria are met, or the maximum number of iterations have been run. If the **Iterations** counter is set to 0, the optimization scheme will be applied until completion, without limit on the maximum number of iterations.

Merge
attempts to decrease the number of interfaces by eliminating orphan cell clusters (an orphan cluster is a group of connected cells whose members each have at least one face coincident with an interface boundary).

Smooth
attempts to minimize the number of interfaces by sacrificing cells on the partition boundary to the neighboring partition to reduce the partition boundary surface area.

Pre-Test
instructs Fluent to test all coordinate directions and choose the one which yields the fewest partition interfaces for the final bisection. Note that this option is available only when you choose **Principal Axes** or **Cartesian Axes** as the partitioning method.

Weighting
tab allows you to set the appropriate weights, prior to partitioning the mesh.

Weight Types
allows you to turn on/off a specific weight. Weight types include: **Faces per Cell** (which is enabled by default, with additional weighting of **2**), **Solid Zones** (available only if solid cell zones are defined); **VOF** (available only if the volume of fluid multiphase model is turned on); **DPM** (available only for discrete phase simulations with injections defined), where you can specify **Hybrid Optimization**; and **ISAT**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Specified
allows you to use the default value (by not selecting the check box), or to specify a value yourself (by selecting the check box and entering a numerical value in the **Value** field.

Value
allows you to enter a user-specified numerical value that either defines the ratio used in the weighting, or (for the **Faces per Cell** weighting) is added to the calculated weight of each cell.

Dynamic Load Balancing
tab allows you to set load balancing thresholds and intervals.

Physical Models
allows you to set thresholds and intervals for the simulation's physical models.

Threshold
is a percentage and depending on the value, load balancing will occur if the load imbalance is greater than the value entered.

Interval
allows you to specify the desired interval for load balancing cycles, in terms of number of iterations. When a value of 0 is specified, ANSYS Fluent will internally determine the best value to use, initially using an interval of 25 iterations. You can override this behavior by specifying a nonzero value. ANSYS Fluent will then attempt to perform load balancing after every N iterations, where N is the specified **Balance Interval**.

Dynamic Mesh
allows you to set load balancing threshold and interval values for your dynamic mesh. This option is only available when the dynamic mesh model is enabled.

Auto
allows a percentage of interface faces and loads to be automatically traced.

Threshold
is a percentage and depending on the value, load balancing will occur if the load imbalance is greater than the value entered.

Interval
allows you to specify the desired interval for load balancing cycles, in terms of number of iterations. When a value of 0 is specified, ANSYS Fluent will internally determine the best value to use, initially using an interval of 25 iterations. You can override this behavior by specifying a nonzero value. ANSYS Fluent will then attempt to perform load balancing after every N iterations, where N is the specified **Balance Interval**.

Mesh Adaption
allows you to set threshold values for mesh adaption.

Threshold
is a percentage and depending on the value, load balancing will occur if the load imbalance is greater than the value entered.

Zones
contains a list of cell zones. Partitioning will be applied to cells in zones selected from this list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Registers
contains a list of cell registers that have been created using the adaption tools. You can restrict partitioning to a group of cells by selecting a register containing the cells. See Partitioning Within Zones or Registers (p. 2043) for details.

Print Active Partitions
(parallel solver only) prints the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each active partition (see Checking the Partitions (p. 2052) for information about active partitions) in the console window. In addition, it prints the minimum and maximum cell, face, interface, and face-ratio variations.

Print Stored Partitions
(parallel solver only) prints the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each stored partition (see Checking the Partitions (p. 2052) for information about stored partitions) in the console window. In addition, it prints the minimum and maximum cell, face, interface, and face-ratio variations.

Print Partitions
(serial solver only) prints the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each stored partition in the console window. In addition, it prints the minimum and maximum cell, face, interface, and face-ratio variations.

Set Selected Zones and Registers to Partition ID
allows you to set a value that assigns selected **Zones** and/or **Registers** to a specific partition ID. A region or zone is marked before setting the marked cells to one of the partition IDs.

Use Stored Partitions
(parallel solver only) allows you to make the stored cell partitions the active cell partitions. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file.

Partition
subdivides the mesh into the selected number of partitions using the prescribed method and optimization(s).

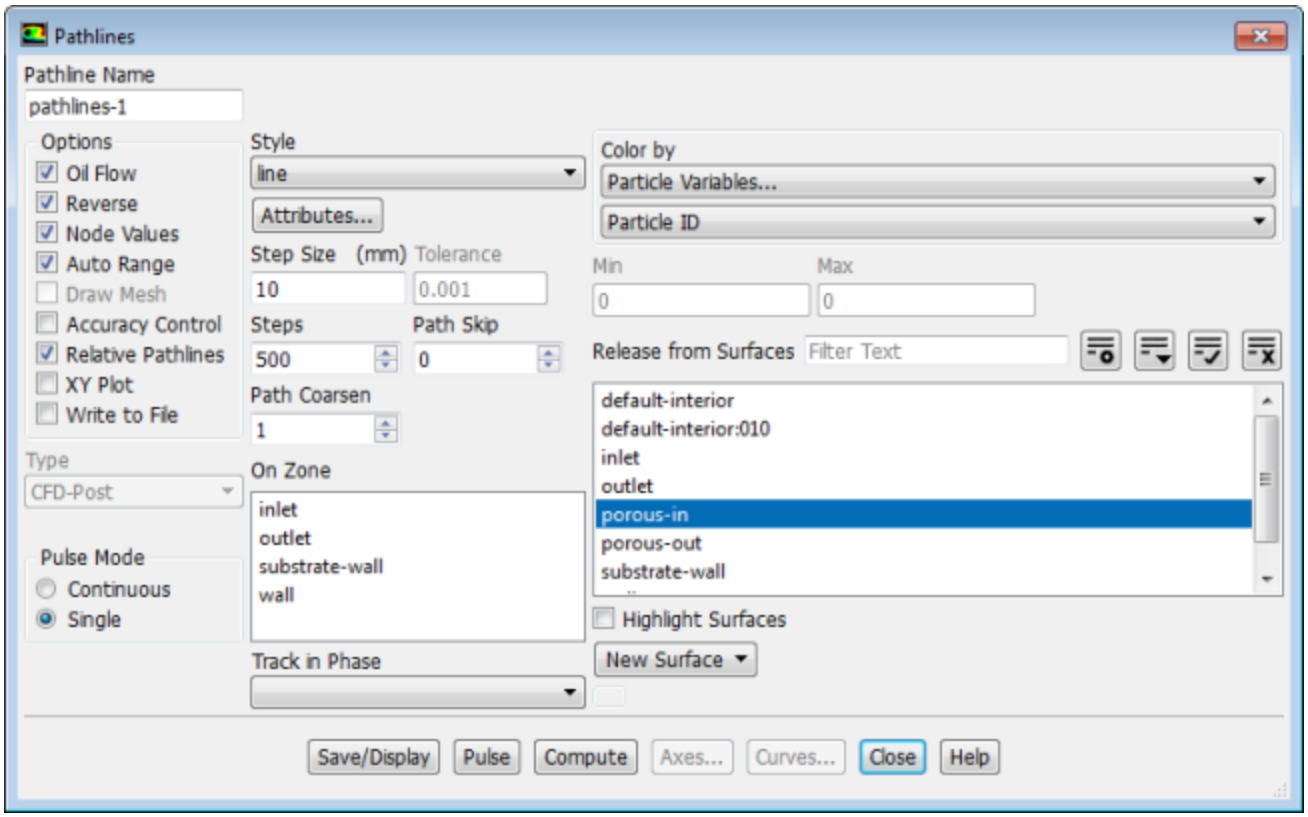
Default
sets all controls to their default values, as assigned by ANSYS Fluent. After execution, the **Default** button becomes the **Reset** button.

Reset
resets the fields to their most recently saved values (that is, the values before **Default** was selected). After execution, the **Reset** button becomes the **Default** button.

38.2.66. Pathlines Dialog Box

The **Pathlines** dialog box controls the generation and display of pathlines. See Displaying Pathlines (p. 1772) for details about the items below.

Postprocessing → **Graphics** → **Pathlines** → **New...**



Controls

Pathline Name
is the name for a pathline definition. You can specify a name or use the default name **`pathline-`*`id`***. This control appears only for pathline definitions.

Options
contains the options described below:

Oil Flow
toggles between regular pathlines and oil-flow pathlines. When this option is selected, pathlines are constrained to lie on the zone selected in the **On Zone** list.

Reverse
specifies that each particle's path is traced back in time. This option is turned off by default.

Node Values
specifies that node values should be interpolated to compute the scalar field at a particle location. This option is turned on by default. See Choosing Node or Cell Values (p. 1780) for details.

Auto Range
specifies that the minimum and maximum values of the scalar field will be the limits of that field. If this option is not selected, you can enter **Min** and **Max** values manually. These values determine the range of the color scale.

Draw Mesh
when enabled opens the Mesh Display Dialog Box (p. 2163) where you can specify how to display your mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Accuracy Control
allows you to specify tolerance to control the pathlines accuracy.

Relative Pathlines
allows you to display the pathlines relative to the rotating reference frame.

XY Plot
enables the display of an XY plot along the pathline trajectories. When this option is selected, the **Display** push button will change to **Plot**.

Write to File
activates the file-writing option. When this option is selected, the **Type** option becomes active and the **Plot** push button will change to **Write...**. Clicking on the **Write...** button will open The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the XY plot data. The format of this file is described in XY Plot File Format (p. 1850).

Type
specifies the type of the file you want to write.

CFD-Post
allows you to write the file in CFD-Post compatible format, which can be read in **CFD-Post**.

Fieldview
allows you to write the file in **FIELDVIEW** format, which can be read in **FIELDVIEW**.

Geometry
allows you to write the file in `.ibl` format, which can be read in GAMBIT.

EnSight
allows you to write the file in `.encas` format, which can be read in EnSight.

Pulse Mode
specifies either a single or continuous release of particles that follow the pathlines, starting at the release surface, when you use the **Pulse** button to animate the pathlines.

Continuous
sets the pulse mode to continuously release particles from the initial positions.

Single
sets the pulse mode to release a single wave of particles.

The **Pulse Mode** is used only when particles are being pulsed.

Style
sets the pathline style. Pathlines can be displayed as lines, ribbons, spheres, cylinders, or a set of points. The **ribbon** style also uses the **Twist By** field and the **TwistFactor** value (specified in the Ribbon Attributes Dialog Box (p. 2560)). Pulsing can be done only on **point** or **line** styles.

Attributes...
opens the Path Style Attributes Dialog Box (p. 2559) or the Ribbon Attributes Dialog Box (p. 2560), depending on the selected **Style**. These dialog boxes allow you to set the attributes (ribbon width, marker size, cylinder radius, twist-by field, and so on) for the chosen pathline style.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Step Size
sets the interval used for computing the next position of a particle. This is in units of length. Particle positions are always computed when they enter/leave a cell. If you specify a very large size, the particle positions at entry/exit of each cell will still be computed (and displayed).

Tolerance
allows you to control the error when using large time step sizes for the calculation. This is available when **Accuracy Control** is selected under **Options**.

Steps
sets the maximum number of steps a particle can advance. A particle's path may also end if it leaves the domain.

Path Skip
allows you to "thin" or "sample" the pathlines that are displayed. See "Thinning" Pathlines (p. 1775) for details.

Path Coarsen
reduces the time and the number of points plotted in a pathline. Coarsening factor of 'n' will result in plotting of each 'n'th point for a given pathline in each cell.

On Zone
contains a list from which you can select the zone on which the particles are constrained to lie. This list is activated only when the **Oil Flow** option is selected.

Track in Phase
(for the Eulerian Multiphase model only) allows you to select the phase or the mixture of all phases for tracking particle pathlines.

Color by
contains a list from which you can select the scalar field to be used to color the pathlines. The default is **Particle ID**, a unique ID for each particle.

Y Axis Function
contains a list of solution variables that can be used for the y axis of the plot.

This item appears when the **XY Plot** option is turned on.

X Axis Function
contains a list of functions for the x axis of the plot. You can plot the quantity selected in the **Y Axis Function** drop-down list as a function of the **Time** elapsed along the trajectory, or the **Path Length** along the trajectory.

This item appears when the **XY Plot** option is turned on.

Min/Max
display the values to which the lower and upper ends of the color scale map. If you are using the **Auto Range** option, these values will be automatically computed when you click **Compute**. If you are not using **Auto Range**, you can enter values manually.

Release from Surfaces
selects the surfaces from which to release particles. You must select at least one surface before any particles can be released.

Highlight Surfaces
when enabled highlights the surfaces (selected in the **Pathlines** dialog box) in the graphics window.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

EnSight Encas File Name
allows you to specify a.encas file name if you selected **EnSight** under **Type**.

Browse...
opens The Select File Dialog Box (p. 19) where you can select the `.encas` file.

Time Steps For EnSight Export
allows you to set the number of time levels that are available for animation in EnSight.

Display
displays the pathlines in the active graphics window.

Save/Display
plots the pathlines in the active graphics window and saves the pathline definition. This button appears only for pathline definitions and replaces the **Display** button.

Plot
displays an XY plot along the pathline trajectories. This button replaces the **Display** button when the **XY Plot** option is turned on.

Write...
opens The Select File Dialog Box (p. 19), in which you can save the XY plot data to a file. This button replaces the **Plot** button when the **Write to File** option is turned on.

Pulse
animates the position of particles. If **Pulse Mode** is set to **Continuous**, particles are reintroduced at the seed positions repeatedly. If the mode is **Single**, a single wave of particles moves through the domain.

The label of this button changes to **Stop !** when the animation is in progress. Click **Stop !** to stop pulsing (and the label goes back to **Pulse**).

Compute
computes the **Min** and **Max** for the field chosen in **Color by**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

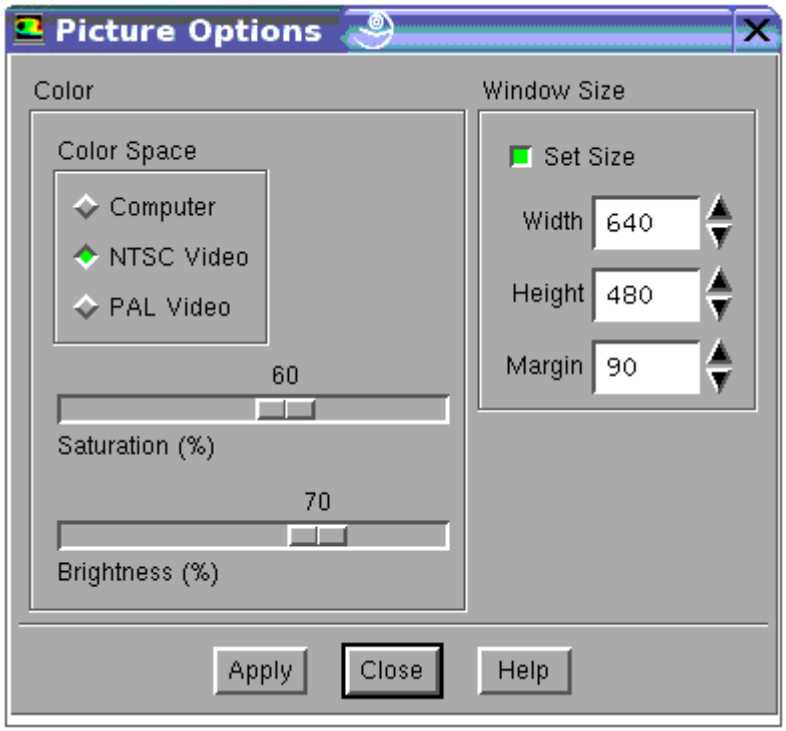
Axes...
opens the Axes Dialog Box (p. 2608), which allows you to customize the XY plot axes. This item appears when the **XY Plot** option is turned on.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to customize the curves used in the XY plot. This item appears when the **XY Plot** option is turned on.

38.2.67. Picture Options Dialog Box

The **Picture Options** dialog box allows you to adjust the color levels and size of the picture in the graphics window. This dialog box has an **Apply** button, so as you adjust levels, you can click **Apply** to see the effect on the picture in the current graphics window. Each option has a presetting, so you can click **Apply** immediately to see the effect of the presettings.

The **Picture Options** dialog box is opened from the Video Control Dialog Box (p. 2833).



Controls

Color
contains options for adjusting the color levels of the picture.

Color Space
lets you choose a filter that will restrict all colors to within a particular color range by modifying individual color values, if needed.

Computer
when selected, effectively turns off color filtering.

NTSC Video
when selected, restricts colors to the NTSC color space. NTSC (National Television Standards Committee) is the main video format used in North America and Japan.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PAL Video
when selected, restricts colors to the PAL color space. PAL (Phase Alternate Line) is the video format used by some countries in Western Europe, Asia, and Australia.

Saturation (%)
controls the percentage of color saturation (or purity) of the colors in the picture. A saturation in the range of 0-20% produces grayed-out colors. A saturation in the range of 40-60% produces pastel colors. A saturation in the range of 80-100% produces vivid colors. For video, this value should be no more than 80%.

Brightness (%)
controls the color brightness of the picture. When lowering the saturation, it is often desirable to lower the brightness a little bit as well to avoid pastel colors.

Window Size
allows you to resize the graphics window so that you can match up the size to your VTR device.

Set Size
lets you decide whether or not you want the **Width**, **Height**, and **Margin** values to be used to resize the graphics window.

Width
specifies the width in pixels of the new window size.

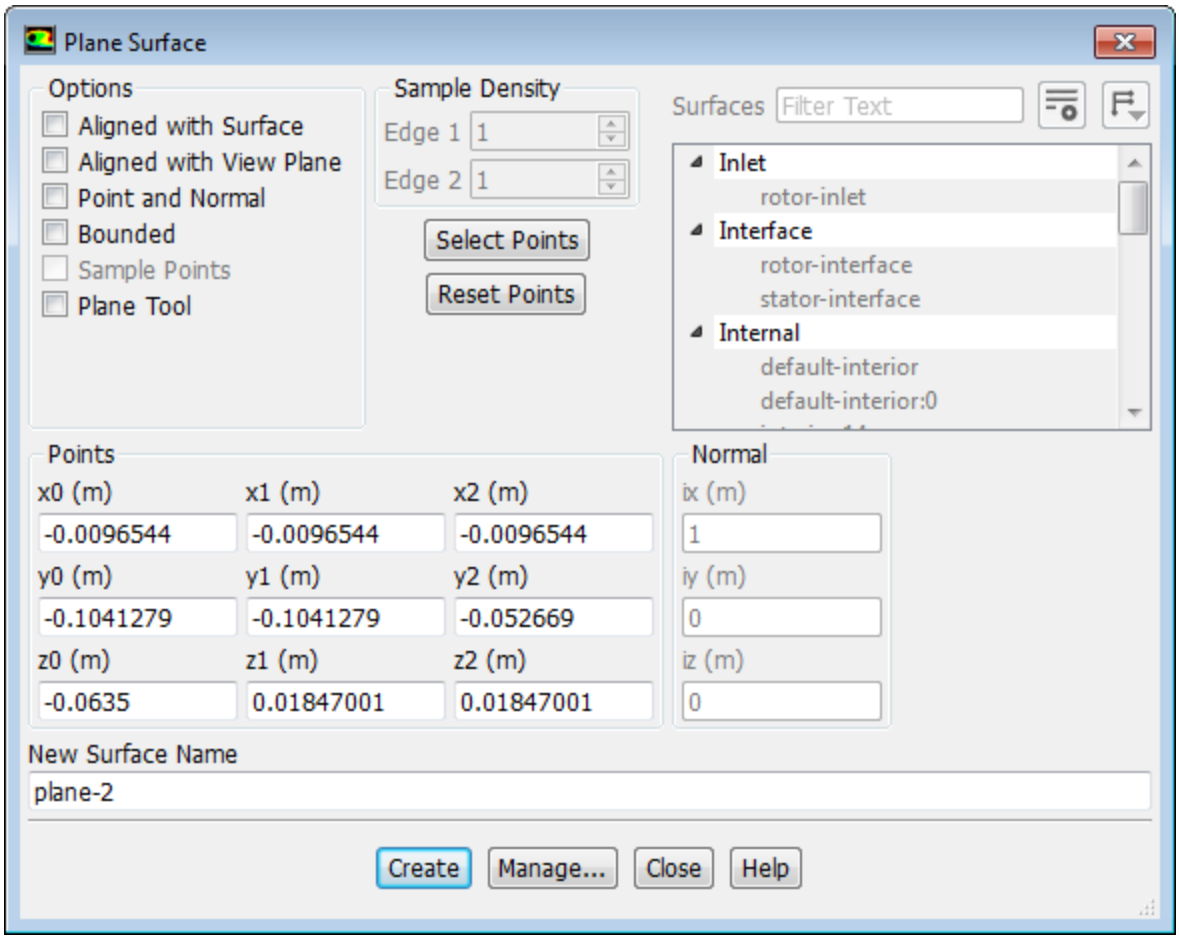
Height
specifies the height in pixels of the new window size.

Margin
specifies a margin in pixels to create around the picture. This can help you produce a video image that does not include unwanted parts of the screen, such as the window border.

38.2.68. Plane Surface Dialog Box

The **Plane Surface** dialog box allows you to interactively create a planar surface that cuts through the domain. See Plane Surfaces (p. 1722) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains options for defining the plane surface.

Aligned with Surface
enables the specification of a plane parallel to an existing surface.

Aligned with View Plane
enables the specification of a plane parallel to the current view in the active graphics window.

Point and Normal
enables the specification of a plane having a certain normal vector and passing through a specified point.

Bounded
enables the creation of a bounded parallelepiped, 3 of whose 4 corners are the 3 points that define the plane equation (or the 4 corners of the **Plane Tool**).

Sample Points
enables the specification of a point density along the 2 directions (of the parallelepiped). This creates a uniformly distributed set of points on the plane. (This item is available only when the **Bounded** option is enabled.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plane Tool
enables the plane tool. See Using the Plane Tool (p. 1724) for details. This option is not available if you are using the **Aligned With Surface** or **Aligned With View Plane** option.

Sample Density
specifies the density of points when the **Sample Points** option is enabled.

Edge 1, Edge 2
sets the point density along the two directions of the plane. (Edge 1 extends from point 0 to point 1, and edge 2 extends from point 1 to point 2.)

Select Points
allows you to select points with the mouse. You can select endpoints by clicking on locations in the active window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)

Reset Points
resets the plane tool to its default position.

Surfaces
contains a list of currently defined surfaces. If you choose the **Aligned With Surface** option, this will become a selectable list, and you can choose the surface that you want the new plane surface to be aligned with.

Points
contains boxes in which you can set the coordinates of the three points defining the planar surface.

x0, y0, z0
designates the coordinates of the first point.

x1, y1, z1
designates the coordinates of the second point.

x2, y2, z2
designates the coordinates of the third point.

Normal
contains boxes in which you can specify the components of the normal vector when the **Point And Normal** option is enabled.

ix, iy, iz
designates the coordinates of the end point of the normal vector (the start point being 0, 0, 0).

New Surface Name
designates the name of the new surface. The default is the concatenation of the surface type and an integer which is the new surface ID.

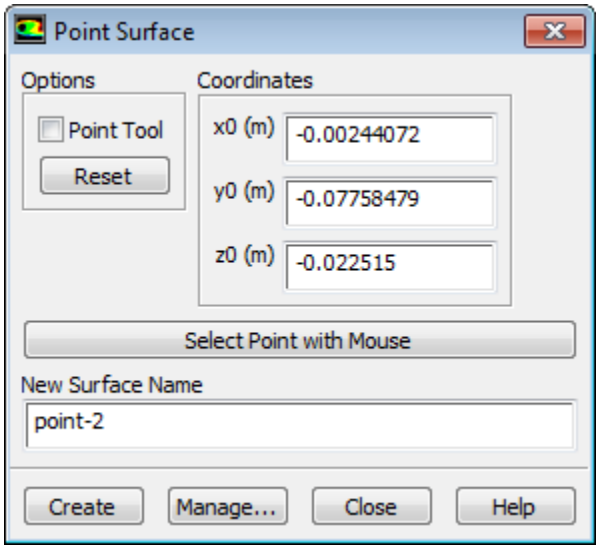
Create
creates the surface.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.69. Point Surface Dialog Box

The **Point Surface** dialog box allows you to interactively create point surfaces (surfaces containing a single data point). See Point Surfaces (p. 1716) for details about the items below.



Controls

Options
contains options related to the point tool. See Using the Point Tool (p. 1717) for details about using this feature.

Point Tool
enables the point tool.

Reset
resets the point tool to its default position.

Coordinates
designates the coordinates of the point in the surface (**x0**, **y0**, **z0**).

Select Point with Mouse
allows you to select the point with the mouse. You can select a point by clicking on a location in the active window with the mouse-probe button. (See Controlling the Mouse Button Functions (p. 1800) for information about setting mouse button functions.)

New Surface Name
designates the name of the new surface. The default is the concatenation of the surface type and an integer which is the new surface ID.

Create
creates the surface.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

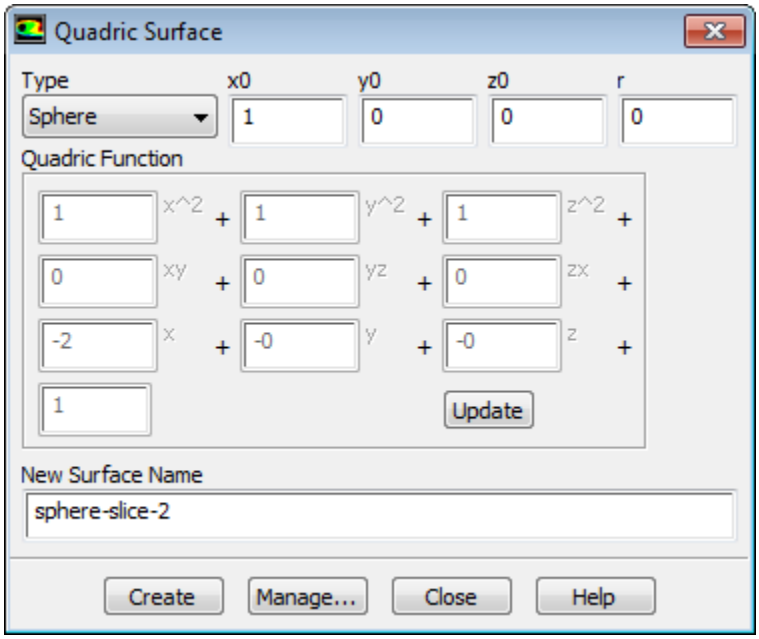
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.70. Quadric Surface Dialog Box

The **Quadric Surface** dialog box allows you to interactively define quadric functions and create surfaces from them. Lines and circles are commonly used types of quadric functions, so additional support is provided for defining them. See Quadric Surfaces (p. 1726) for details about using the items below.

Important

Note that your inputs for the quadric function must be in SI units.



Controls

Type
selects the type of quadric function. Presently, you may select **Line/Plane**, **Circle/Sphere** or a general **Quadric**. Some of the control buttons take on different meanings for each of the three quadric function types.

Line/Plane
specifies that the surface will consist of all points on the domain that satisfy the equation $ix*x+iy*y+iz*z=distance$, where

ix
is the coefficient of x in the quadric function.

iy
is the coefficient of y in the quadric function.

iz
is the coefficient of z in the quadric function.

distance
is the distance of the line/plane from the origin.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you click the **Update** button in **Quadric Function**, the coefficients in the quadric function will change to reflect your inputs.

Circle/Sphere
specifies that the surface will consist of all points in the domain that satisfy the equation $(x-x0)^2+(y-y0)^2+(z-z0)^2=r^2$, where

x0,y0,z0
are the x, y, z coordinates of the center.

r
is the radius.

When you click the **Update** button in **Quadric Function**, the coefficients in the quadric function will change to reflect your inputs.

Quadric
specifies that the surface will consist of all points in the domain that satisfy the quadric function $Q=value$, where Q is the quadric function you define as shown below. You will enter **value** to the right of the **Type** entry, but the coefficients in the quadric function are entered directly in the **Quadric Function** box. Note that in 2D problems the z entries are ignored.

x2, y2, z2, xy, yz, zx, x, y, z
are the coefficients of the corresponding terms in the quadric function.

Quadric Function
contains the display of the quadric function and the **Update** button. If you select **Line/Plane** or **Circle/Sphere** as the **Type**, the coefficients of the quadric function will be updated here when you click the **Update** button. You will not be able to edit the values in the **Quadric Function** box directly. If you select **Quadric** as the **Type**, you will enter the coefficients directly in this box, and the **Update** button will be inactive.

Update
updates the coefficients in **Quadric Function** to reflect the current input.

New Surface Name
designates the name of the new surface. The default is the concatenation of the surface type and an integer which is the new surface ID.

Create
creates the surface.

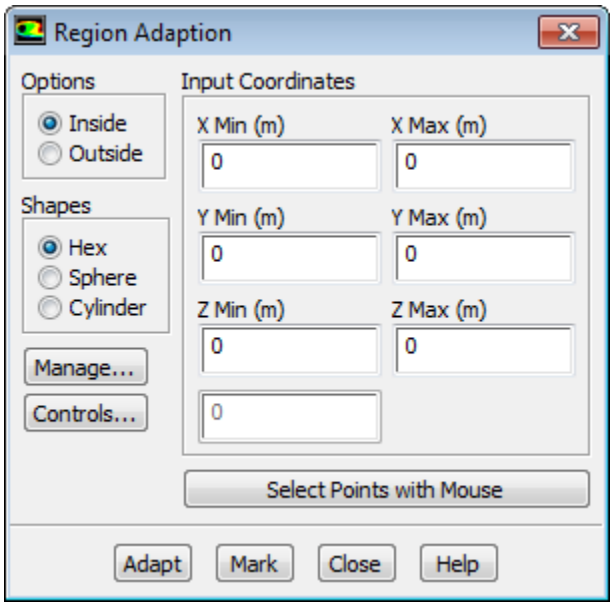
Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

38.2.71. Region Adaption Dialog Box

The **Region Adaption** dialog box allows you to mark or refine cells inside or outside a specified region defined by text or mouse input. See Region Adaption (p. 1692) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Region...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains radio buttons that control whether the cells inside or outside the region are marked for refinement.

Inside
enables the marking of cells with centroids that are within the region.

Outside
enables the marking of cells with centroids that are outside the region.

Shapes
contains radio buttons that control the type of region.

Hex/Quad
defines a hexahedral region in 3D or a rectangular region in 2D. The appropriate button will appear for the solver you are using.

Sphere/Circle
defines a spherical region in 3D or a circular region in 2D. The appropriate button will appear for the solver you are using.

Cylinder
defines a cylindrical region in 3D or a rectangular region in 2D.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Input Coordinates
defines the extent of the selected region. The appearance of this box changes depending on the type of region selected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the region selected is a hexahedron or quadrilateral, you will specify the minimum and maximum coordinates defining the box. (The **Radius** real number field will not be active.)

X Min, Y Min, Z Min
define the coordinates of the minimum point defining the hexahedron or rectangle. For quadrilaterals, the **Z Min** real entry field will not be active.

X Max, Y Max, Z Max
define the coordinates of the maximum point defining the hexahedron or rectangle. For quadrilaterals, the **Z Max** real entry field will not be active.

If the region selected is a sphere or circle, you will specify the coordinates of the sphere's center and its radius. (The maximum coordinate real number fields will not be active.)

X Center, Y Center, Z Center
are the coordinates of the centroid of the sphere or circle. For circles, the **Z Center** real entry field will not be active.

Radius
is the radius of the sphere or circle.

If the region selected is a cylinder, you will specify the minimum and maximum coordinates defining the cylinder axis, as well as the radius of the cylinder.

X-Axis Min, Y-Axis Min, Z-Axis Min
define the coordinates of the minimum point defining the cylinder axis. For 2D cases, the **Z-Axis Min** real entry field will not be active.

X-Axis Max, Y-Axis Max, Z-Axis Max
define the coordinates of the maximum point defining the cylinder axis. For 2D cases, the **Z-Axis Max** real entry field will not be active.

Radius
is the radius of the cylinder. (In 2D, this will be the width of the resulting rectangle.)

Select Points with Mouse
allows you to select specify coordinates with the mouse. If one of the mouse buttons is defined as a mouse probe, you may select the input coordinates from a display of the mesh or solution field. For more information on mouse buttons, refer to Controlling the Mouse Button Functions (p. 1800). After you select the points, the values will be loaded automatically into the appropriate real number field. You have the option of editing these values before marking or adapting. The order of input for defining a hexahedron (rectangle) is insignificant, but the order of input for the sphere (circle) has significance. First, you select the location of the centroid. Then you select a point that lies on the sphere, that is, a point that is one radius away from the centroid.

Adapt
adapts the mesh based on the region defined and the in/out option.

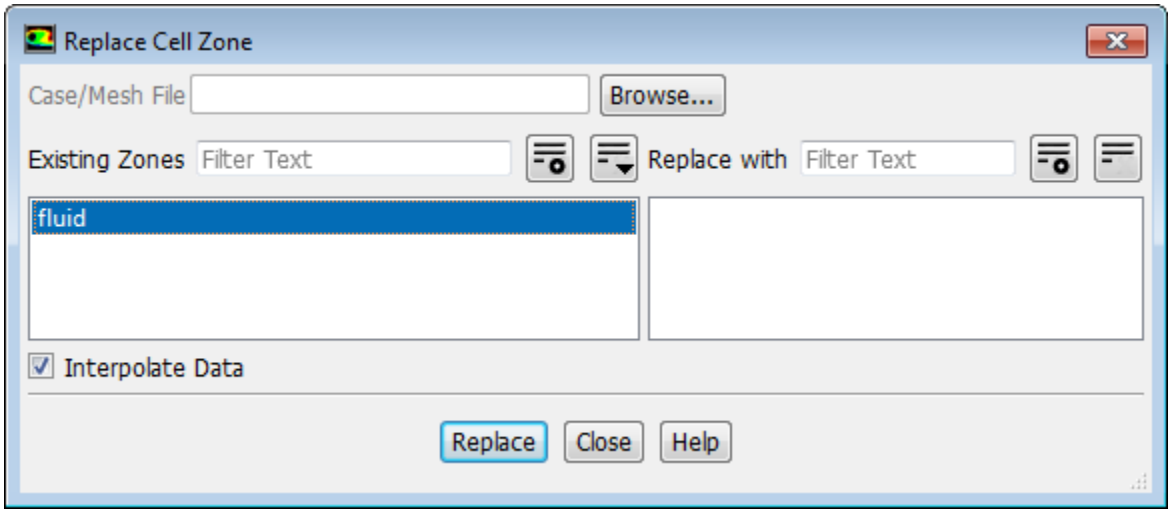
Mark
marks the cells to be refined based on the region defined and the in/out option. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.72. Replace Cell Zone Dialog Box

The **Replace Cell Zone** dialog box allows you to replace a single cell zone or multiple zones. See Replacing Zones (p. 218) for details.

Setting Up Domain → Zones → Replace Zone...



Controls

Case/Mesh File
allows you to specify a mesh file from which you want to replace the zone.

Existing Zones
contains a list of cell zones from which you can select the zone to be replaced.

Replace with
contains a list of cell zones from which you can select the zone to replace the zone selected in **Existing Zones** list.

Interpolate Data
allows you to enable/disable data interpolation if data already exists.

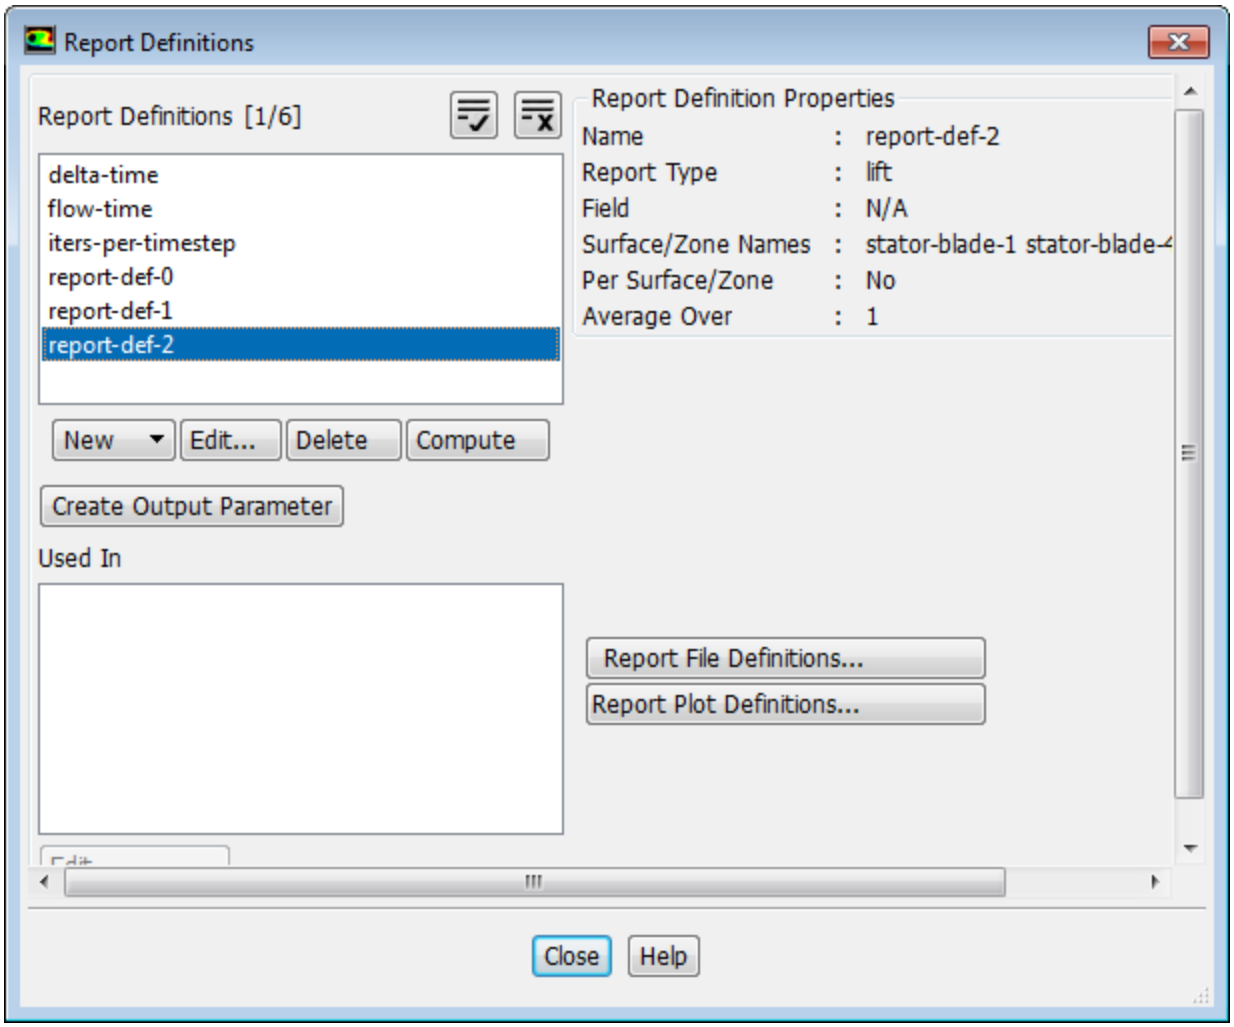
Replace
replaces the selected cell zone.

38.2.73. Report Definitions Dialog Box

Solving → Reports → Definitions → Edit...

For information on creating report definitions, see Monitoring and Reporting Solution Data (p. 1885).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Report Definitions
lists all of the existing report definitions.

New
drop-down list allowing you to create new report definitions (surface, volume, force, flux, dpm, and user-defined).

Edit...
allows you to edit the properties of the selected report definition.

Delete
deletes the selected report definition.

Compute
computes the value of the selected report definition and prints to the console.

Create Output Parameter
creates an output parameter for the selected report definition(s) with the name `<report definition name>-op`.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Used In
lists the report files and report plots that contain the selected report definition.

Edit...
opens the report file/plot dialog box for the report file/plot selected in the **Used In** list.

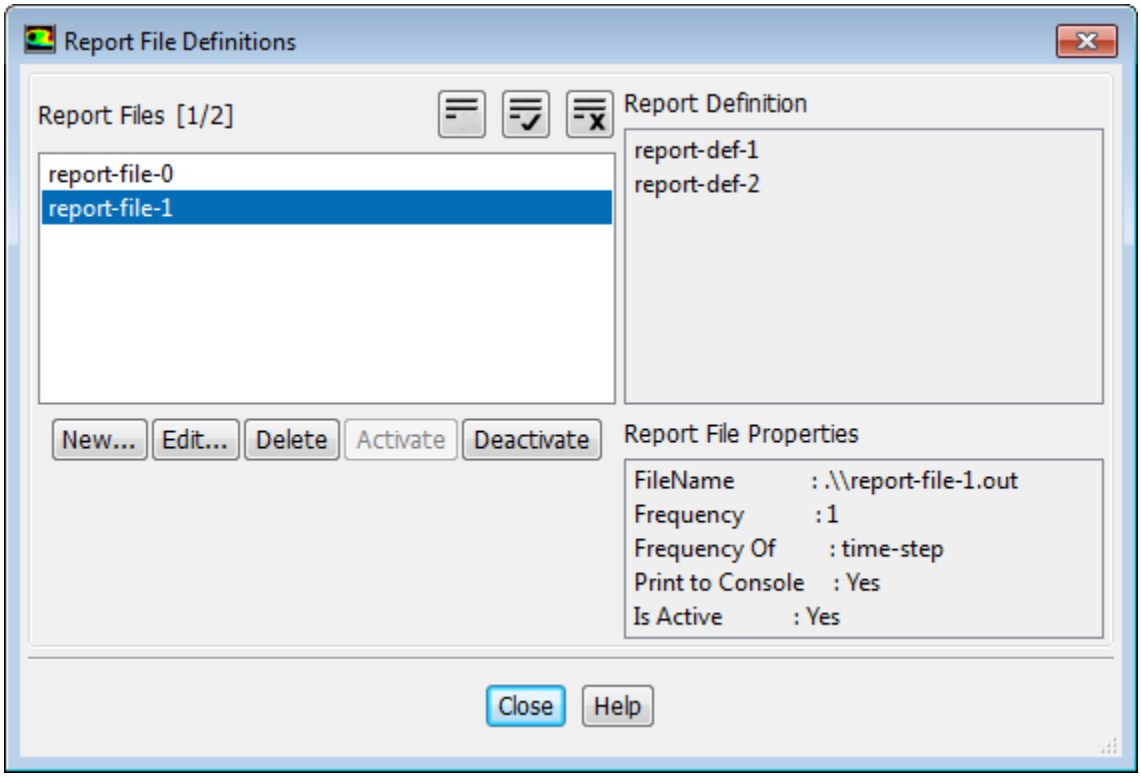
Report Definition Properties
displays the properties of the selected report definition in the **Report Definition** list.

Report File Definitions...
opens the Report File Definitions Dialog Box (p. 2787).

Report Plot Definitions
opens the Report Plot Definitions Dialog Box (p. 2788).

38.2.74. Report File Definitions Dialog Box

Solving → Reports → File...



Controls

Report Files
lists all of the existing report files.

New...
opens the New Report File Dialog Box (p. 2754).

Edit...
allows you to edit the properties of the selected report file in the Edit Report File Dialog Box (p. 2698).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Delete
deletes the selected report file.

Activate
activates the selected (previously deactivated) report file for writing during the solution calculation.

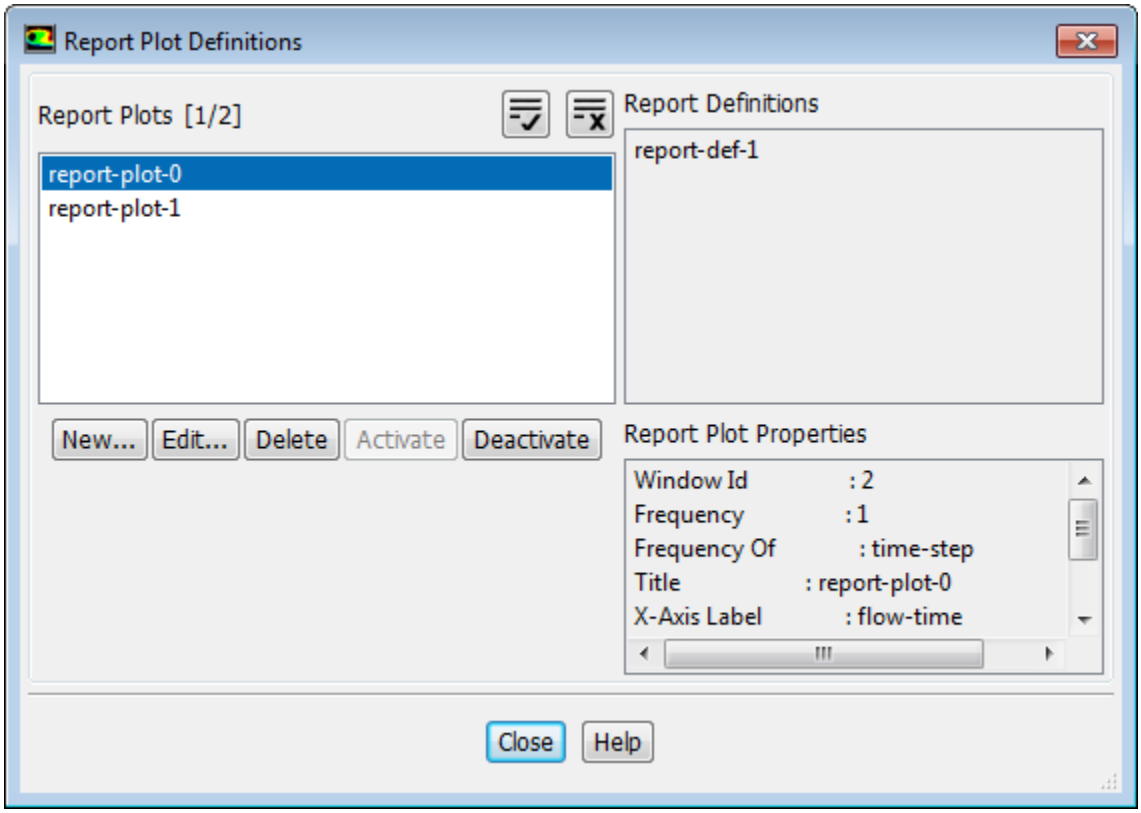
Deactivate
deactivates the writing of the selected report file during the solution calculation.

Report Definition
lists the report definitions included in the selected report file.

Report File Properties
lists the properties of the selected report file.

38.2.75. Report Plot Definitions Dialog Box

Solving → Reports → Plot...



Controls

Report Plots
lists all of the existing report plots.

New...
opens the New Report Plot Dialog Box (p. 2755).

Edit...
allows you to edit the properties of the selected report plot in the Edit Report Plot Dialog Box (p. 2700).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Delete
deletes the selected report plot.

Activate
activates the selected (previously deactivated) report plot for plotting during the solution calculation.

Deactivate
deactivates the plotting of the selected report plot during the solution calculation.

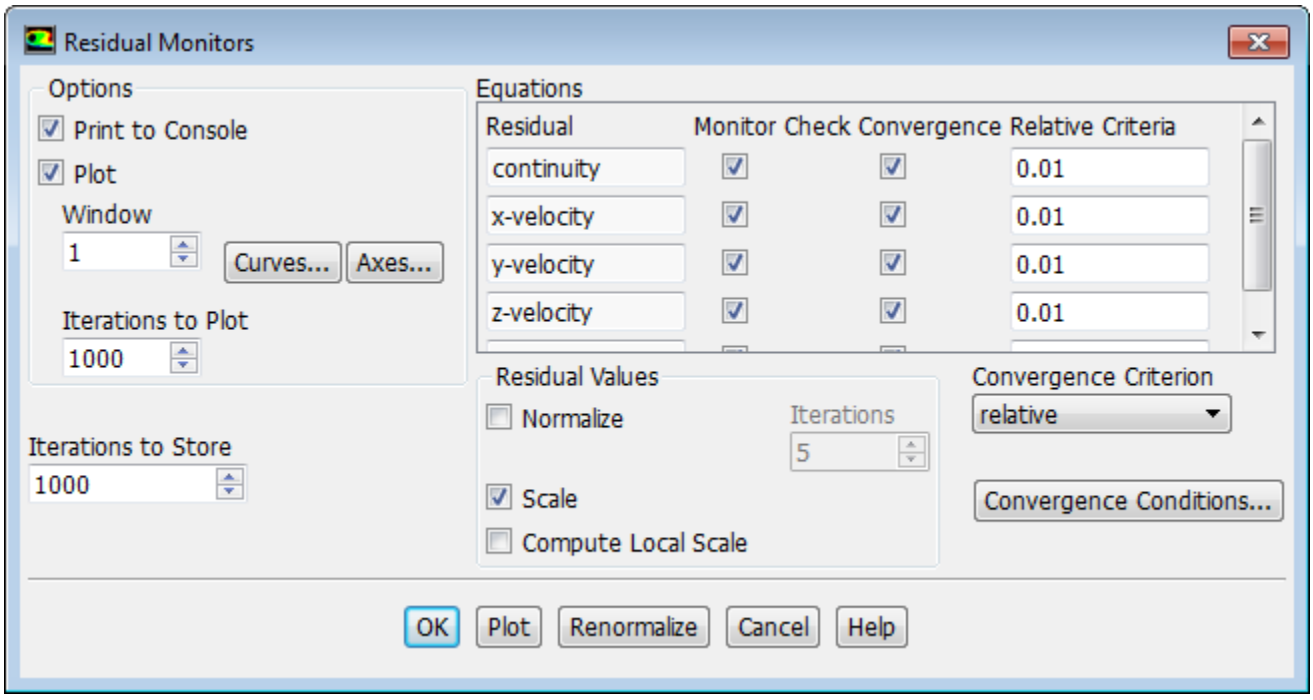
Report Definition
lists the report definitions included in the selected report plot.

Report Plot Properties
lists the properties of the selected report plot.

38.2.76. Residual Monitors Dialog Box

You can use the **Residual Monitors** dialog box to control the residual information that Fluent reports. See Monitoring Residuals (p. 1624) for details about the items below.

Solving → Reports → Residuals...



Controls

Options
selects any combination of the following methods for reporting residuals. See Printing and Plotting Residuals (p. 1627) for details.

Print to Console
specifies whether or not to print residuals in the text window after each iteration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plot
specifies whether or not to plot residuals in the graphics window (with the window ID set in **Window**) after each iteration. See Plot Parameters (p. 1632) for details.

Window
sets the window ID in which the plot will be drawn. When ANSYS Fluent is iterating, the active graphics window is temporarily set to this window to update the residual plot, and then returned to its previous value. Thus, the residual plot can be maintained in a separate window that does not interfere with other graphical postprocessing.

Iterations to Plot
is the number of history points to display on the residual plot.

Axes...
opens the Axes Dialog Box (p. 2608), which allows you to modify the attributes of the axes.

Curves...
opens the Curves Dialog Box (p. 2610), which allows you to modify the attributes of the residual curves.

Iteration to Store
sets the number of residual history points to be stored in the data file. Due to the compaction algorithm used, saving 1000 points does not result in just the last 1000 iterations being saved; the history reaches back quite a bit further than that, but does not save a point at every iteration. Further back in the iteration history, the spacing between saved iterations grows larger. See Storing Residual History Points (p. 1628) for details.

Residual Values
controls the normalization and scaling of residuals. See Controlling Normalization and Scaling (p. 1628) for details.

Normalize
specifies whether or not to normalize the printed or plotted residual for each variable by the value indicated as the **Normalization Factor** for that variable. The default **Normalization Factor** is the maximum residual value after the first 5 iterations.

This option is off by default.

Iterations
sets the number of iterations for which ANSYS Fluent will search for the largest residual to normalize by. (If the **Normalize** option is turned off, this item will not be editable.)

Scale
specifies whether or not to print or plot scaled residuals for each variable. This option is on by default.

Compute Local Scale
computes and stores both the locally and globally scaled residuals from subsequent iterations, for the purpose of reporting. You will select the type of residual scaling form the **Reporting Option** drop-down list. See Definition of Residuals for the Pressure-Based Solver (p. 1624) and Definition of Residuals for the Density-Based Solver (p. 1626) for more information.

Reporting Option
gives you the choice of plotting or printing to the console the **global scaling** or **local scaling** of residuals.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Convergence Criterion
consists of four options that are available for checking an equation for convergence.

absolute
is the default and is available for steady-state cases. The residual (scaled and/or normalized) of an equation at an iteration is compared with a user-specified value. If the residual is less than the user-specified value, that equation is deemed to have converged for a time step.

relative
is where the residual of an equation at an iteration of a time step is compared with the residual at the start of the time step. If the ratio of the two residuals is less than a user-specified value, that equation is deemed to have converged for a time step.

relative or absolute
is where either the **absolute** convergence criterion or the **relative** convergence criterion is met. At that point, the equation is considered converged.

none
is used to disable convergence checking.

Convergence Conditions...
opens the Convergence Conditions Dialog Box (p. 2678).

Residual
indicates the name of each variable for which residual information is available.

Monitor
indicates whether or not the residuals for each variable are to be monitored. You can toggle monitoring on and off for each variable by turning the corresponding check box in the **Monitor** list on or off.

Normalization Factor
shows the normalization factor for each variable. The default is the maximum residual value after the first 5 iterations. To set this value manually, enter a new value in the corresponding **Normalization Factor** field. This list will not appear if the **Normalize** option is turned off.

Check Convergence
indicates whether or not the convergence of each variable is to be monitored. If convergence is being monitored, the solution will stop automatically when each variable meets its specified convergence criterion. You can check convergence only for variables for which you are monitoring residuals. You can toggle convergence checking on and off for each variable by turning the corresponding check box in the **Check Convergence** list on or off.

Absolute Criteria, Relative Criteria
shows the residual value for which the solution of each variable will be considered to be converged. To set this value manually, enter a new value in the corresponding **Absolute Criteria**/**Relative Criteria** field.

Plot
displays the current residual history plot.

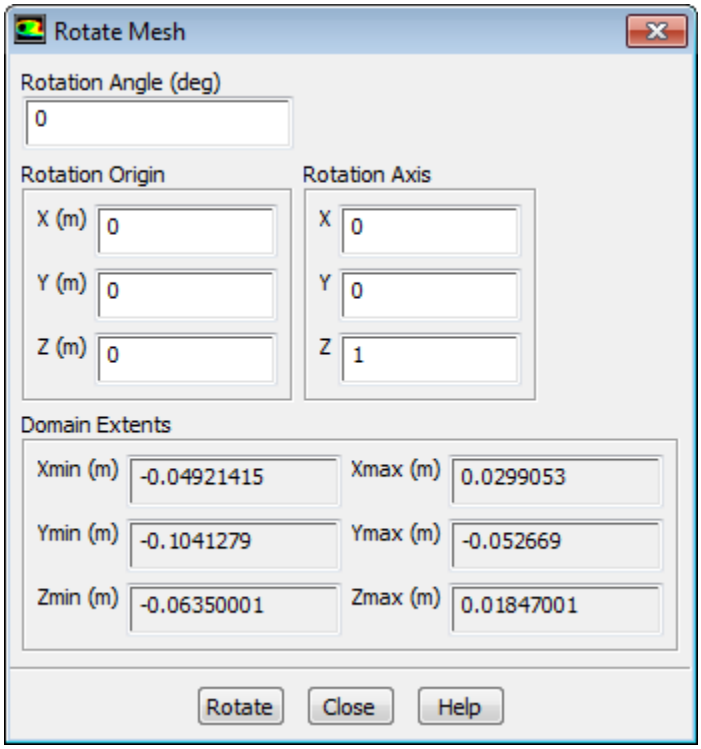
Renormalize
sets the normalization factors to the maximum values in the residual histories. **Renormalize** should be used to renormalize the residual plot in cases where the maximum residuals occur sometime after the first five iterations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.77. Rotate Mesh Dialog Box

The **Rotate Mesh** dialog box allows you to rotate the mesh about the required axis and rotation origin by specifying the angle of rotation. See Rotating the Mesh (p. 229) for details.

Setting Up Domain → Mesh → Transform → Rotate...



Controls

Rotation Angle
is the angle with which you want to rotate the mesh. You can enter a positive or negative real number.

Rotation Origin
defines the new origin for the mesh rotation.

Rotation Axis
defines the axis about which you want to rotate the mesh.

Domain Extents
displays the Cartesian coordinate extremes of the nodes in the mesh. (These values are not editable; they are purely informational.)

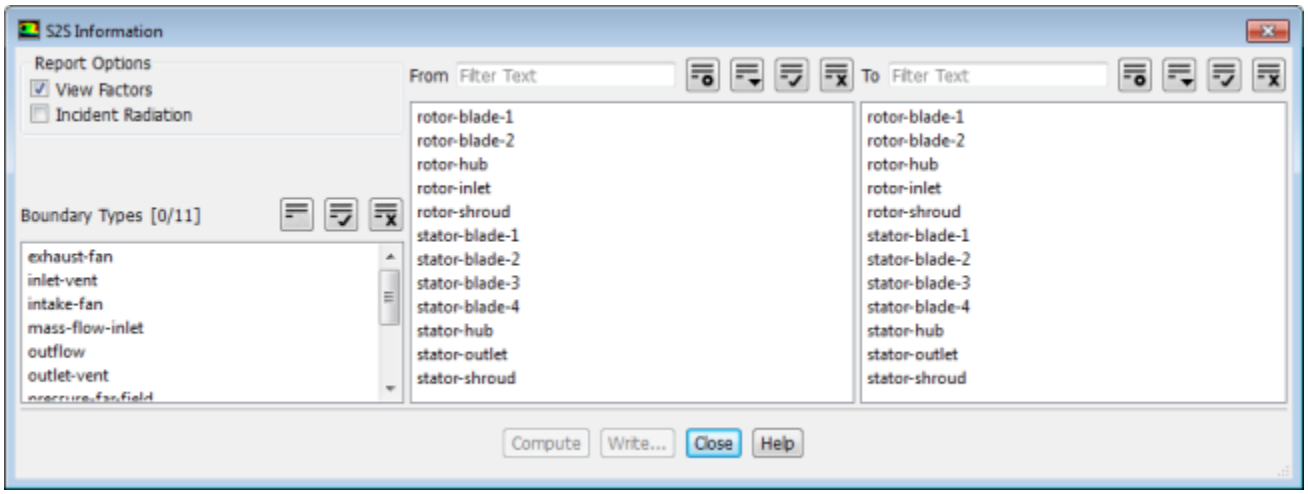
Rotate
adds the specified rotation parameters to the appropriate Cartesian coordinate of every node in the mesh.

38.2.78. S2S Information Dialog Box

The **S2S Information** dialog box allows you to report values of the view factor and radiation emitted from one zone to any other zone. See Reporting Radiation in the S2S Model (p. 885) for details about the items below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Postprocessing → Model Specific → S2S Information...



Controls

Report Options
contains items for which information is available for reporting.

View Factors
turns on the computation of view factors from one zone to the other.

Incident Radiation
turns on the computation of the incident radiation from one zone to the other.

Boundary Types
contains a selectable list of types of boundary zones. If you select (or deselect) an item in this list, all zones of that type will be selected (or deselected) automatically in the **From** and **To** lists.

From
contains a selectable list of boundary zones for which you would like data reported from the selected zone.

To
contains a selectable list of boundary zones for which you would like data reported to the selected zone.

Compute
computes the view factors and/or incident radiation on the selected zones.

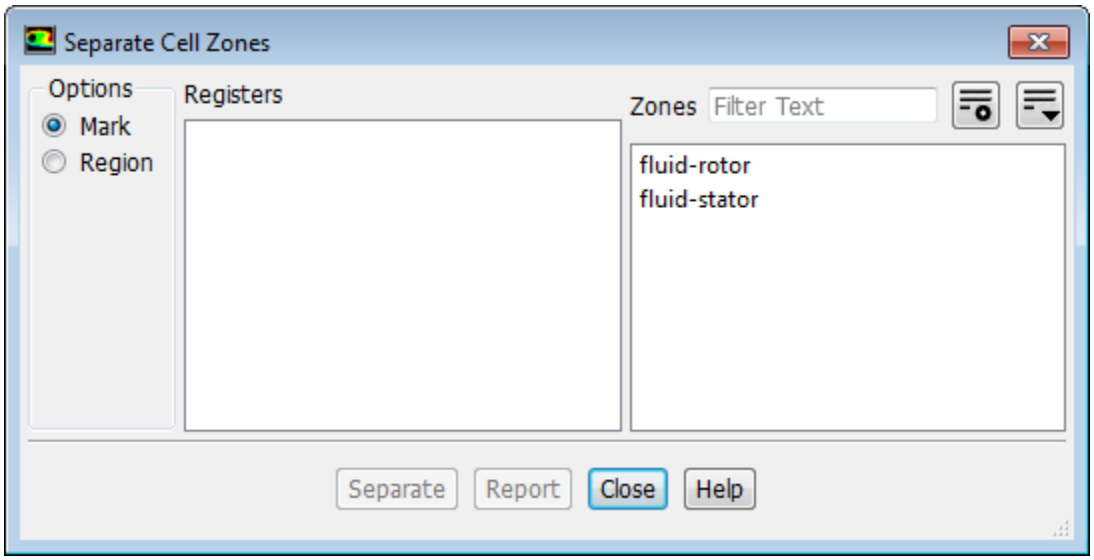
Write...
opens The Select File Dialog Box (p. 19), which you can use to save the data as an S2S Info File (`.sif` format).

38.2.79. Separate Cell Zones Dialog Box

The **Separate Cell Zones** dialog box allows you to separate a single cell zone into multiple zones of the same type. See Separating Zones (p. 208) for details.

Setting Up Domain → Zones → Separate → Cells...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
specifies the method on which the cell-zone separation is to be based.

Mark
indicates that the cell zone is to be separated based on the marks stored in adaption registers.

Region
indicates that the cell zone is to be separated into two or more contiguous regions based on an internal boundary within the original zone.

Registers
contains a list of defined adaption registers. If you are separating the cell zone by mark, select the adaption register to be used in the **Registers** list. When the separation is performed, cells that are marked will be placed into a new zone.

Zones
contains a list of cell zones from which you can select the zone to be separated.

Separate
separates the selected cell zone based on the specified parameters.

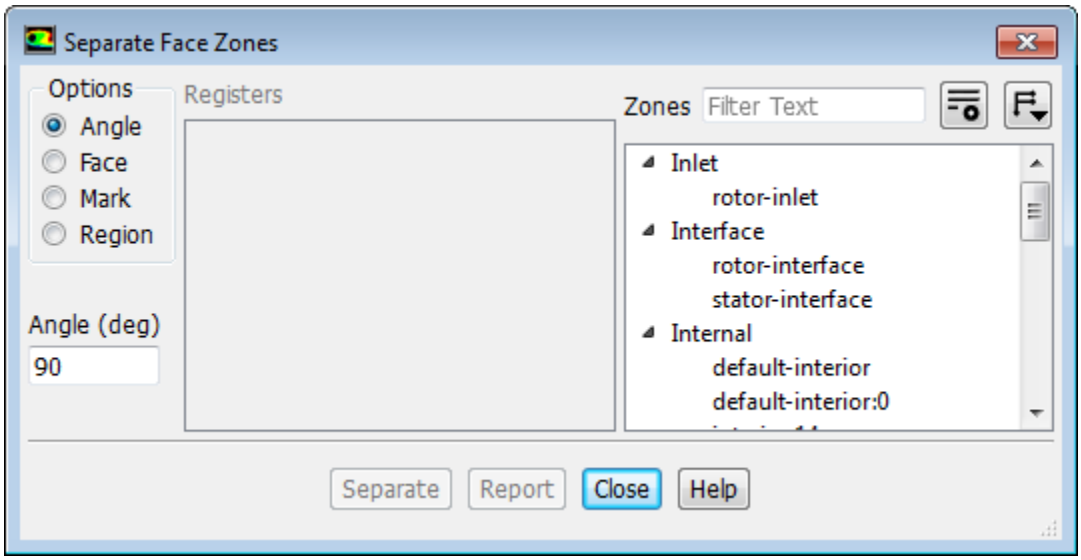
Report
reports what the result of the separation will be without actually separating the cell zone.

38.2.80. Separate Face Zones Dialog Box

The **Separate Face Zones** dialog box allows you to separate a single face zone into multiple zones of the same type. See Separating Zones (p. 208) for details.

Setting Up Domain → Zones → Separate → Faces...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
specifies the method on which the face separation is to be based.

Angle
indicates that the face zone is to be separated based on significant angle (specified in the **Angle** field).

Face
indicates that the face zone is to be separated by putting each face in the zone into its own zone.

Mark
indicates that the face zone is to be separated based on the marks stored in adaption registers.

Region
indicates that the face zone is to be separated based on contiguous regions.

Registers
contains a list of defined adaption registers. If you are separating faces by mark, select the adaption register to be used in the **Registers** list. When the separation is performed, all faces of cells that are marked will be placed into a new face zone.

Zones
contains a list of face zones from which you can select the zone to be separated.

Angle
specifies the significant angle to be used when you separate a face zone based on angle. Faces with normal vectors that differ by an angle greater than or equal to the specified significant angle will be placed in different zones when the separation occurs.

Separate
separates the selected face zone based on the specified parameters.

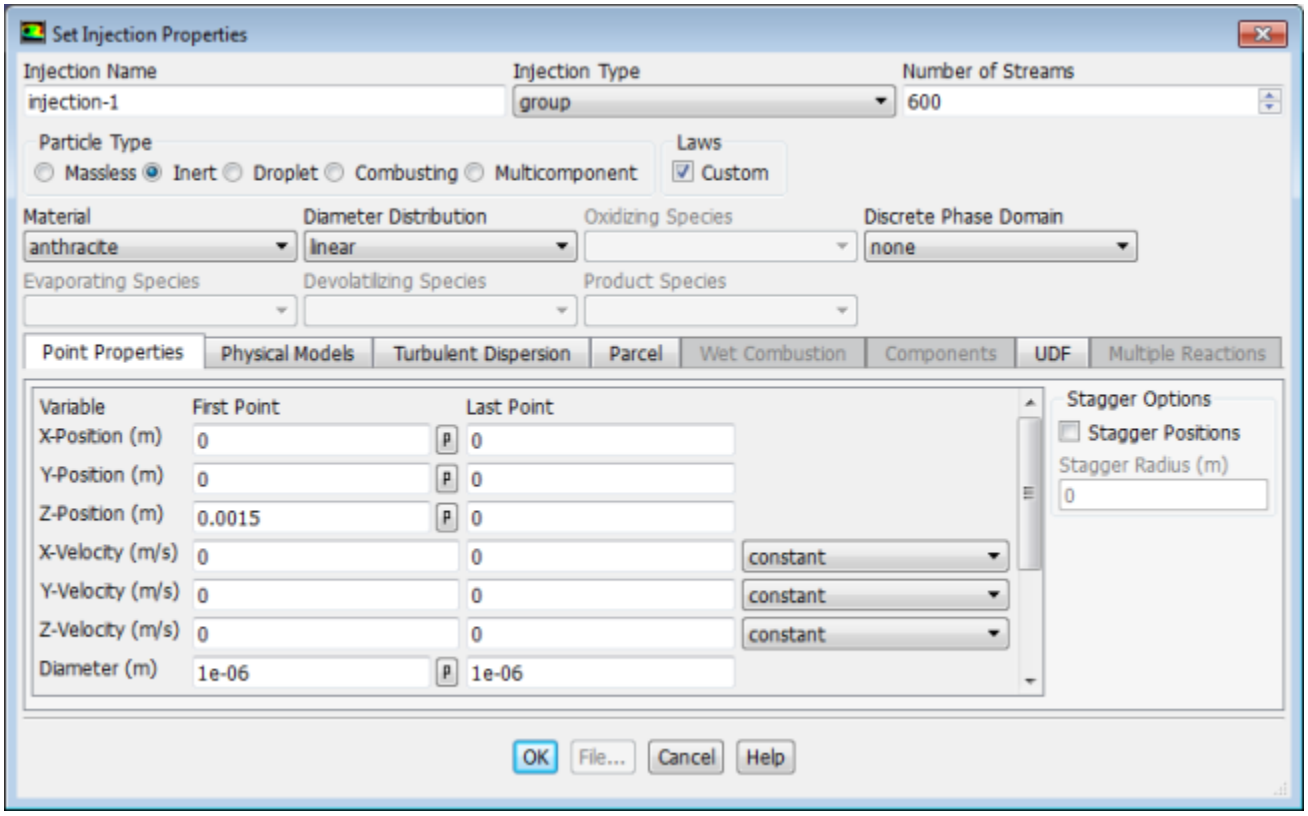
Report
reports what the result of the separation will be without actually separating the face zone.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.81. Set Injection Properties Dialog Box

The **Set Injection Properties** dialog box allows you to define the properties of an existing discrete-phase injection (which was created in the Injections Dialog Box (p. 2716)). See Defining Injection Properties (p. 1286) for details about the items listed in this section.

The **Set Injection Properties** dialog box is opened from the Injections Dialog Box (p. 2716).



Controls

Injection Name

sets the name of the injection.

Injection Type

contains a drop-down list of the available injection types: **single**, **group**, **cone**, **surface**, **plain-orifice-atomizer**, **pressure-swirl-atomizer**, **air-blast-atomizer**, **flat-fan-atomizer**, **effervescent-atomizer**, and **file**. (**cone** is not available in 2D.) These choices are described in Injection Types (p. 1266).

Number of Streams

indicates the number of particle streams in a **group**, **cone**, or any of the **atomizer** injections. (This item will not appear for **single**, **surface**, or **file** injections.)

Release From Surfaces

indicates the surface from which the particles in a **surface** injection will be released. (This item will appear only for a **surface** injection.)

Particle Type

specifies the particle type as **Massless**, **Inert**, **Droplet**, **Combusting**, or **Multicomponent**. These types are described in Particle Types (p. 1268).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Laws
(not for massless particles) contains inputs for customized particle laws.

Custom
enables the specification of customized particle laws and opens the Custom Laws Dialog Box (p. 2684).

Material
(not for massless particles) indicates the material for the particles. If this is the first time you have created a particle of this type, you can choose from all of the materials by copying them from the database or creating them from scratch, as discussed in Setting Discrete-Phase Physical Properties (p. 1316) and described in detail in Using the **Create/Edit Materials** Dialog Box (p. 461).

Diameter Distribution
(not for massless particles) allows you to change from the default **linear** interpolation method used to determine the size of the particles in a **group** injection, or the default **uniform** method used to determine the size of the particles in a **surface** injection, to the **rosin-rammler** or **rosin-rammler-logarithmic** method. The Rosin-Rammler method for determining the range of diameters is described in Using the Rosin-Rammler Diameter Distribution Method (p. 1281).

Evaporating Species
(for **droplet** particles) specifies the gas-phase species created by the vaporization and boiling laws (laws 2 and 3).

Devolatilizing Species
(for **combusting** particles) specifies the gas-phase species created by the devolatilization law (law 4).

This item will not appear for two-mixture-fraction non-premixed combustion calculations.

Devolatilizing Stream
(for **combusting** particles) specifies the destination stream for the gas-phase species created by the devolatilization law (law 4).

This item will appear only for two-mixture-fraction non-premixed combustion calculations.

Oxidizing Species
(for **combusting** particles) specifies the gas phase species that participates in the surface char combustion reaction (law 5).

Product Species
(for **combusting** particles) specifies the gas-phase species created by the surface char combustion reaction (law 5).

This item will not appear for two-mixture-fraction non-premixed combustion calculations.

Product Stream
(for **combusting** particles) specifies the destination stream for the gas-phase species created by the surface char combustion reaction (law 5).

This item will appear only for two-mixture-fraction non-premixed combustion calculations.

Discrete Phase Domain
is available when using the **Dense Discrete Phase Model**, described in Including the Dense Discrete Phase Model (p. 1481).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DEM Collision Partner
is available when using the **DEM Collision** model, described in Modeling Collision Using the DEM Model (p. 1253).

Point Properties
displays the inputs for the point properties for the injection (for example, position, velocity, diameter, temperature, and mass flow rate). These inputs are described for each injection type in Point Properties for Single Injections (p. 1269) – Point Properties for Effervescent Atomizer Injections (p. 1280).

First Point
specifies the first point properties for the injection.

Last Point
specifies the last point properties for the injection.

Physical Models
displays the inputs for injection-specific physics models.

Drag Parameters
allows the setting of the drag law used in calculating the force balance on the particles. See Particle Force Balance in the Theory Guide for details on the items below.

Drag Law
is a drop-down list containing the available choices for the drag law:

spherical
assumes that the particles are smooth spheres.

nonspherical
assumes that the particles are not spheres, but are all identically shaped. The shape is specified by the **Shape Factor**.

Stokes-Cunningham
is for use with sub-micron particles. A **Cunningham Correction** is added to Stokes' drag law to determine the drag.

high-Mach-number
is similar to the spherical law with corrections to account for a particle Mach number greater than 0.4 or a particle Reynolds number greater than 20.

Ishii-Zuber
is used in gas-liquid flows. This drag law is only available if the magnitude and direction of the gravity vector are specified in the **Operating Conditions** dialog box. See Ishii-Zuber Drag Model in the *Fluent Theory Guide* for details.

Grace
is used in gas-liquid flows. This drag law is only available if the magnitude and direction of the gravity vector are specified in the **Operating Conditions** dialog box. See Grace Drag Model in the *Fluent Theory Guide* for details.

dynamic-drag
accounts for the effects of droplet distortion. This drag law is available only when one of the droplet breakup models is used in conjunction with unsteady tracking. See Dynamic Drag Model Theory in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Shape Factor
specifies the shape of the particles when **nonspherical** is selected as the **Drag Law** (φ in Equation 16.75 in the Theory Guide). It is the ratio of the surface area of a sphere having the same volume as the particle to the actual surface area of the particle. The shape factor value cannot be greater than 1.

Cunningham Correction
(C_c in Equation 16.77 in the Theory Guide) is used with Stokes' drag law to determine the force acting on the particles when the particles are sub-micron size. It appears when **Stokes-Cunningham** is selected as the **Drag Law**.

Particle Rotation
contains settings for the modeling of particle rotation when the **Enable Rotation** check box is selected (see Wall-Particle Reflection Model Theory in the *Fluent Theory Guide*).

Rotational Drag Law
is a drop-down list of available rotational drag law models:

Dennis-et-al
uses Equation 16.4 in the *Fluent Theory Guide* to calculate the rotational drag coefficient C_ω.

none
implies zero torque, that is, it excludes the influence of the fluid on the rotational particle motion.

Magnus Lift Law
is a drop-down list of available Magnus lift law models:

Oesterle-Bui-Dinh
uses Oesterle and Bui Dinh's formulation (Equation 16.18 in the *Fluent Theory Guide*).

Tsuji-et-al
is based on the particle spin rate (Equation 16.19 in the *Fluent Theory Guide*).

Rubinow-Keller
uses a linear dependence of the rotational lift coefficient C_{RL} on the spin rate (Equation 16.21 in the *Fluent Theory Guide*).

none
implies that the Magnus lift will not be included in your simulation.

Brownian Motion
enables the incorporation of the effects of Brownian motion. This option is available only when the **Stokes-Cunningham** drag law is selected from the **Drag Law** drop-down list. See Brownian Force in the Theory Guide for details.

Breakup
contains parameters that control droplet breakup and collision. (This section of the dialog box appears only if **Unsteady Tracking** is enabled in the Discrete Phase Model Dialog Box (p. 2278).)

Enable Breakup
enables breakup for this injection.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Breakup Model

is a drop-down list containing parameters that control droplet breakup. (This item appears only if **Enable Breakup** is selected.)

TAB

enables the Taylor Analogy Breakup (TAB) model, which is applicable to many engineering sprays. This method is based upon Taylor's analogy between an oscillating and distorting droplet and a spring mass system. See Taylor Analogy Breakup (TAB) Model in the Theory Guide for details.

For the **TAB** model, you must specify the following constants:

y0

is the constant y_0 in Equation 16.370 in the Theory Guide.

Breakup Parcels

is the number of child parcels the droplet is split into, as described in Velocity of Child Droplets in the Theory Guide.

Wave

enables the Wave breakup model, which considers the breakup of the injected liquid to be induced by the relative velocity between the gas and liquid phases. See Wave Breakup Model for details.

For the **Wave** model, you must specify the following constants:

B0

is the constant B_0 in Equation 16.397 in the Theory Guide.

B1

is the constant B_1 in Equation 16.399 in the Theory Guide.

KHRT

enables the Kelvin-Helmholtz Rayleigh-Taylor breakup model, which considers the two competing effects of aerodynamic breakup and instabilities due to droplet acceleration. See KHRT Breakup Model in the Theory Guide for details.

For the **KHRT** model, you must specify the following constants:

B0

is the constant B_0 in Equation 16.397 in the Theory Guide.

B1

is the constant B_1 in Equation 16.399 in the Theory Guide.

Ctau

is the constant C_τ in Equation 16.404 in the Theory Guide.

CRT

is the constant C_{RT} in Equation 16.405 in the Theory Guide.

CL

is the constant C_L in Equation 16.400 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SSD

enables the stochastic secondary droplet breakup model, where the probability of breakup is independent of the parent droplet size and the secondary droplet size is sampled from an analytical solution of the Fokker-Planck equation for the probability distribution. See Stochastic Secondary Droplet (SSD) Model in the Theory Guide for details.

For the **SSD** model, you must specify the following constants:

Critical We

is the critical Weber number in Equation 16.406 in the Theory Guide.

Core B1

is B in Equation 16.407 in the Theory Guide.

Target Np

is the average number in parcels for daughter parcels.

Xi

is $\langle \xi \rangle$ in Equation 16.408 in the Theory Guide.

Turbulent Dispersion

displays the inputs for stochastic tracking and cloud tracking.

Stochastic Tracking

controls the stochastic tracking for turbulent flows. Stochastic tracking includes the effect of turbulent velocity fluctuations on the particle trajectories using the DRW model described in Stochastic Tracking in the Theory Guide. See Stochastic Tracking (p. 1294) for details about the items below.

Discrete Random Walk Model

includes the effect of instantaneous turbulent velocity formulations on the particle trajectories through stochastic method.

Random Eddy Lifetime

specifies that the characteristic lifetime of the eddy is to be random.

Number of Tries

controls the inclusion of turbulent velocity fluctuations.

An input of 1 or greater tells ANSYS Fluent to include turbulent velocity fluctuations in the particle force balance.

Time Scale Constant

is C_L in Equation 16.24 in the Theory Guide. The default is 0.15; if you use the RSM, a value of 0.3 is recommended.

Cloud Tracking

incorporates the effects of turbulent dispersion on the injection. For details on the following items, see Particle Cloud Tracking in the Theory Guide and Cloud Tracking (p. 1296).

Cloud Model

enables particle cloud tracking.

Min. Cloud Diameter

specifies the diameter of the cloud in which the particles enter the domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Max. Cloud Diameter
specifies the maximum allowed cloud diameter.

Parcel
displays the inputs for controlling the discrete phase parcels.

Parcel Definitions
contains settings for how parcels are defined

Parcel Release Method
specifies the method for releasing parcels. Available settings are **standard**, **constant-number**, **constant-mass**, and **constant-diameter**. See Steady/Transient Treatment of Particles (p. 1242) for details about these settings.

Wet Combustion
displays the inputs for the wet combustion model.

Wet Combustion Model
allows the combusting particles to include an evaporating/boiling material.

Liquid Material
contains a drop-down list of liquid materials that can be chosen as the evaporating/boiling material to be included with the combusting particles.

Liquid Fraction
sets the volume fraction of the liquid present in the particle.

Components
displays the inputs for **Multicomponent** for use in the definition of the particle injection. For details on the following items, see Vapor Liquid Equilibrium Theory in the Theory Guide.

Multicomponent Settings
contains the multicomponent injections.

Component
specifies the component that is a part of the multicomponent species.

Mass Fraction
specifies the mass fraction of the component in a multicomponent species.

Evaporating Species
specifies the gas-phase species to be evaporated.

Evaporating Stream
specifies the source stream from which the species will be evaporated.

UDF
displays the inputs for **User-Defined Functions** for use in the definition of the particle injection. For details about user-defined functions, see the separate Fluent Customization Manual.

Initialization
contains a drop-down list of available user-defined functions. The UDF that you choose will be used to modify the injection properties at the time the particles are injected into the domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Heat/Mass Transfer
allows you to select the user-defined function that defines the heat or mass transfer.

Multiple Reactions
displays the inputs for **Multiple Surface Reactions**. See Particle Surface Reactions (p. 1001) for details about this model.

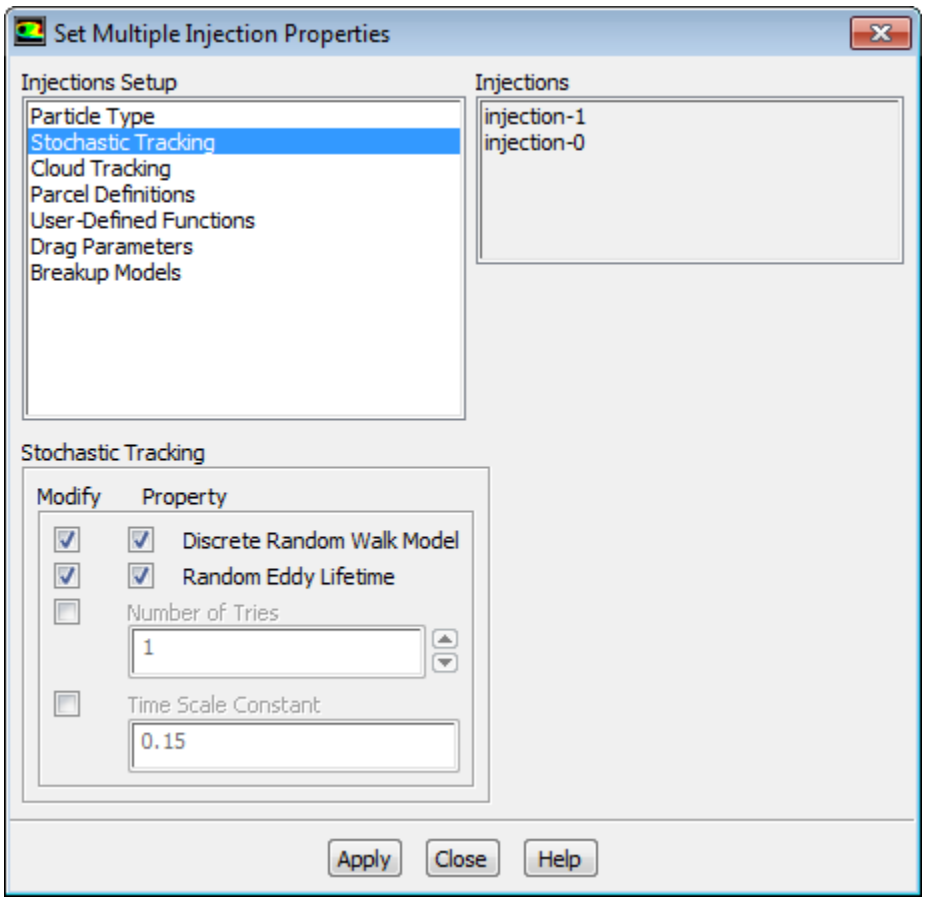
Species Mass Fractions
specify the combustible fraction of the combusting particle if you have defined more than one particle surface species. See Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion (p. 1002) for details.

File...
opens The Select File Dialog Box (p. 19), in which you can select a file containing the injection definition (when **file** is selected as the **Injection Type**).

38.2.82. Set Multiple Injection Properties Dialog Box

The **Set Multiple Injection Properties** dialog box allows you to set properties that are common to multiple injections. See Defining Properties Common to More than One Injection (p. 1297) for details about the items below.

The **Set Multiple Injection Properties** dialog box is opened from the Injections Dialog Box (p. 2716).



Controls

Injections Setup
contains a list of the categories of injection properties that you can set for the injections in the **Injections** list. These categories correspond to the categories of inputs in the Set Injection Properties Dialog Box (p. 2796). When you select an item in the **Injections Setup** list, the dialog box will expand to show the relevant inputs, which are the same as those in the **Set Injection Properties** dialog box.

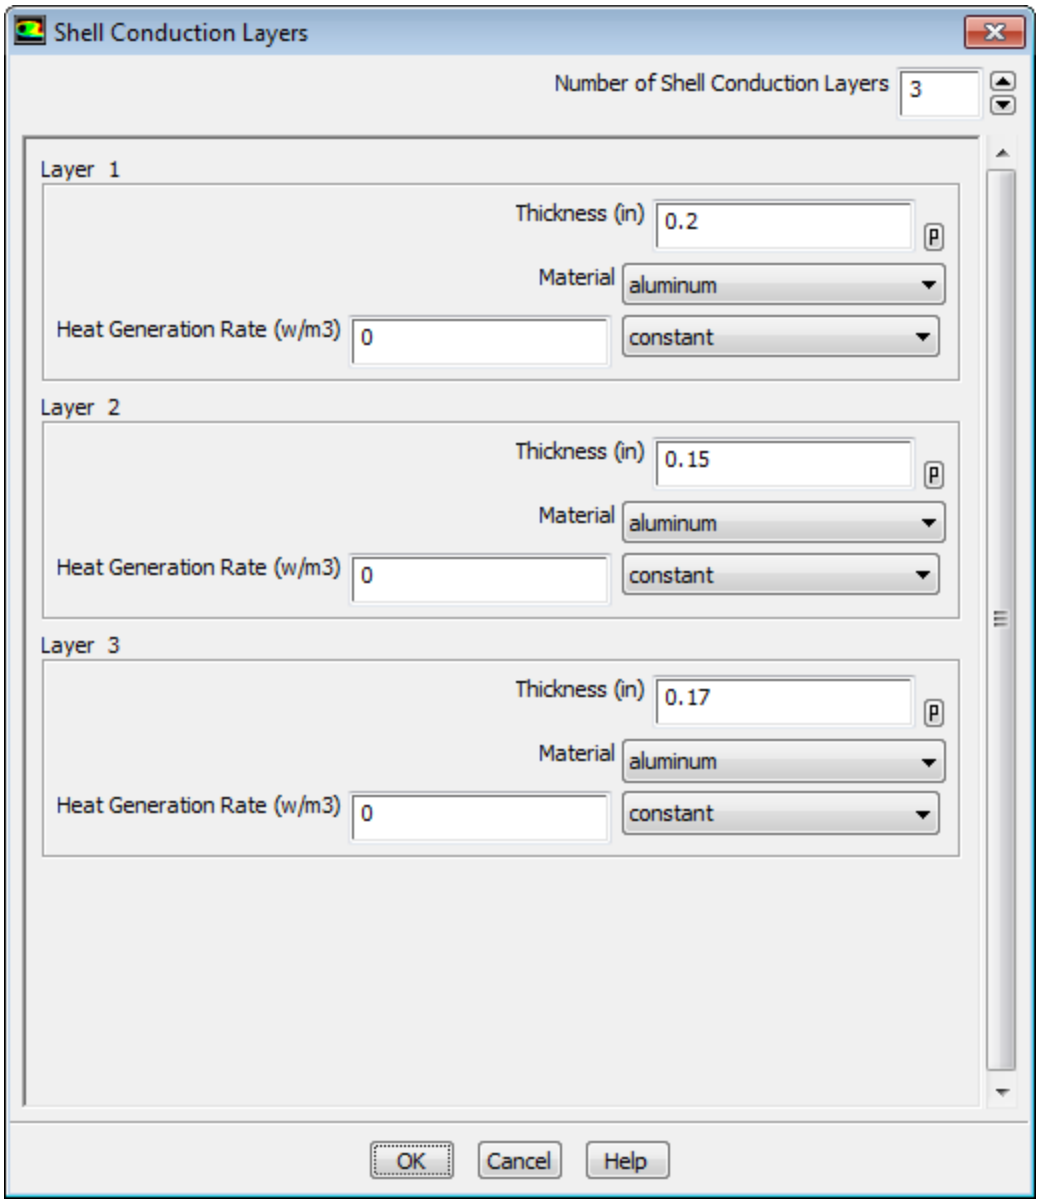
Injections
displays an informational list of the injections for which you are setting common properties. These are the injections that you selected in the Injections Dialog Box (p. 2716).

38.2.83. Shell Conduction Layers Dialog Box

The **Shell Conduction Layers** dialog box allows you to define the shell conduction settings for either a single **Wall** dialog box or all of the walls selected in the **Shell Conduction Zones** list of the Shell Conduction Manager Dialog Box (p. 2806). See Shell Conduction (p. 376) and Managing Shell Conduction Walls (p. 840) for details about the items below.

The **Shell Conduction Layers** dialog box is opened from either the Wall Dialog Box (p. 2456) or the Shell Conduction Manager Dialog Box (p. 2806).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of Shell Conduction Layers

allows you to define the number of layers that make up the wall(s).

Layer 1, Layer 2...

allows you to define the settings for each layer. Note that **Layer 1** refers to the layer closest to the fluid / solid adjacent to the wall zone, and layers with higher numbers are further away.

Thickness

sets the thickness of the layer for the calculation of the shell thermal resistance. Each layer must have a nonzero thickness

Material Name

sets the material type for the layer. The conductivity of the material is used for the calculation of shell thermal resistance. Materials are defined using the Materials Task Page (p. 2300).

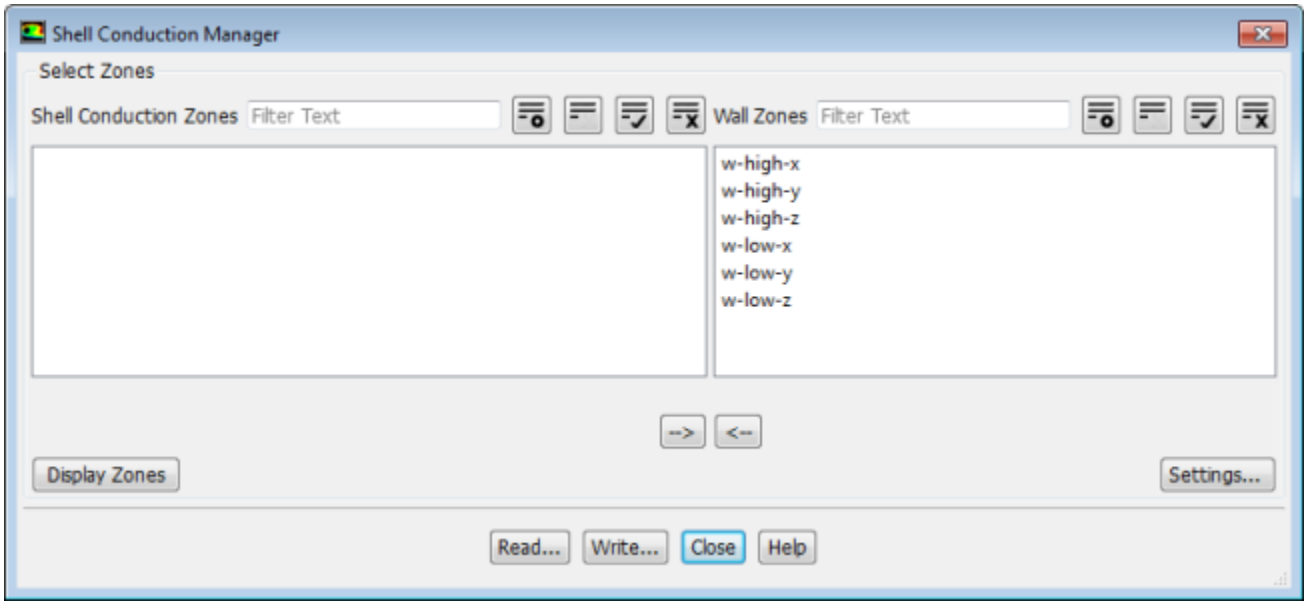
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Heat Generation Rate
sets the rate of heat generation in the layer. Note that you have the option of defining the heat generation rate using a user-defined function (UDF) that utilizes the `DEFINE_PROFILE` macro; for more information on creating and using user-defined functions, see the Fluent Customization Manual.

38.2.84. Shell Conduction Manager Dialog Box

The **Shell Conduction Manager** dialog box allows you to manage, define, and display shell conduction zones all in one location. See Managing Shell Conduction Walls (p. 840) for details about using the **Shell Conduction Manager** dialog box.

Setting Up Physics → Model Specific → Shell Conduction...



Controls

Select Zones
contains the list of **Shell Conduction Zones** and **Wall Zones**.

Shell Conduction Zones
contains a list of zones with shell conduction enabled.

Wall Zones
contains a list of zones without shell conduction.

-> , <-
disables and enables shell conduction for a selected zone, respectively.

Display Zones
displays the selected walls in the graphics window. Note that you can select walls with or without shell conduction. The zones will be displayed with different colors depending on the option selected in Mesh Colors Dialog Box (p. 2168) (accessible from the Mesh Display Dialog Box (p. 2163)).

Settings...
opens the Shell Conduction Layers Dialog Box (p. 2804), where you can define the shell properties of the walls selected in the **Shell Conduction Zones** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Read...
allows you to define your shell conduction settings by reading a CSV file.

Write...
allows you to write your saved shell conduction settings to a CSV file.

38.2.85. Surface Meshes Dialog Box

The **Surface Meshes** dialog box allows you to read the surface meshes in ANSYS Fluent (See Reading Surface Mesh Files (p. 149) for details on reading surface meshes.)

The **Surface Meshes** dialog box is opened from the Geometry Based Adaption Dialog Box (p. 2709).

Controls

Surfaces
contains a list of the surfaces available in the surface mesh you read.

*You can select/deselect the surfaces listed under **Surfaces**.*

Read...
opens the **Select File** dialog box in which you can select the surface mesh you want to read.

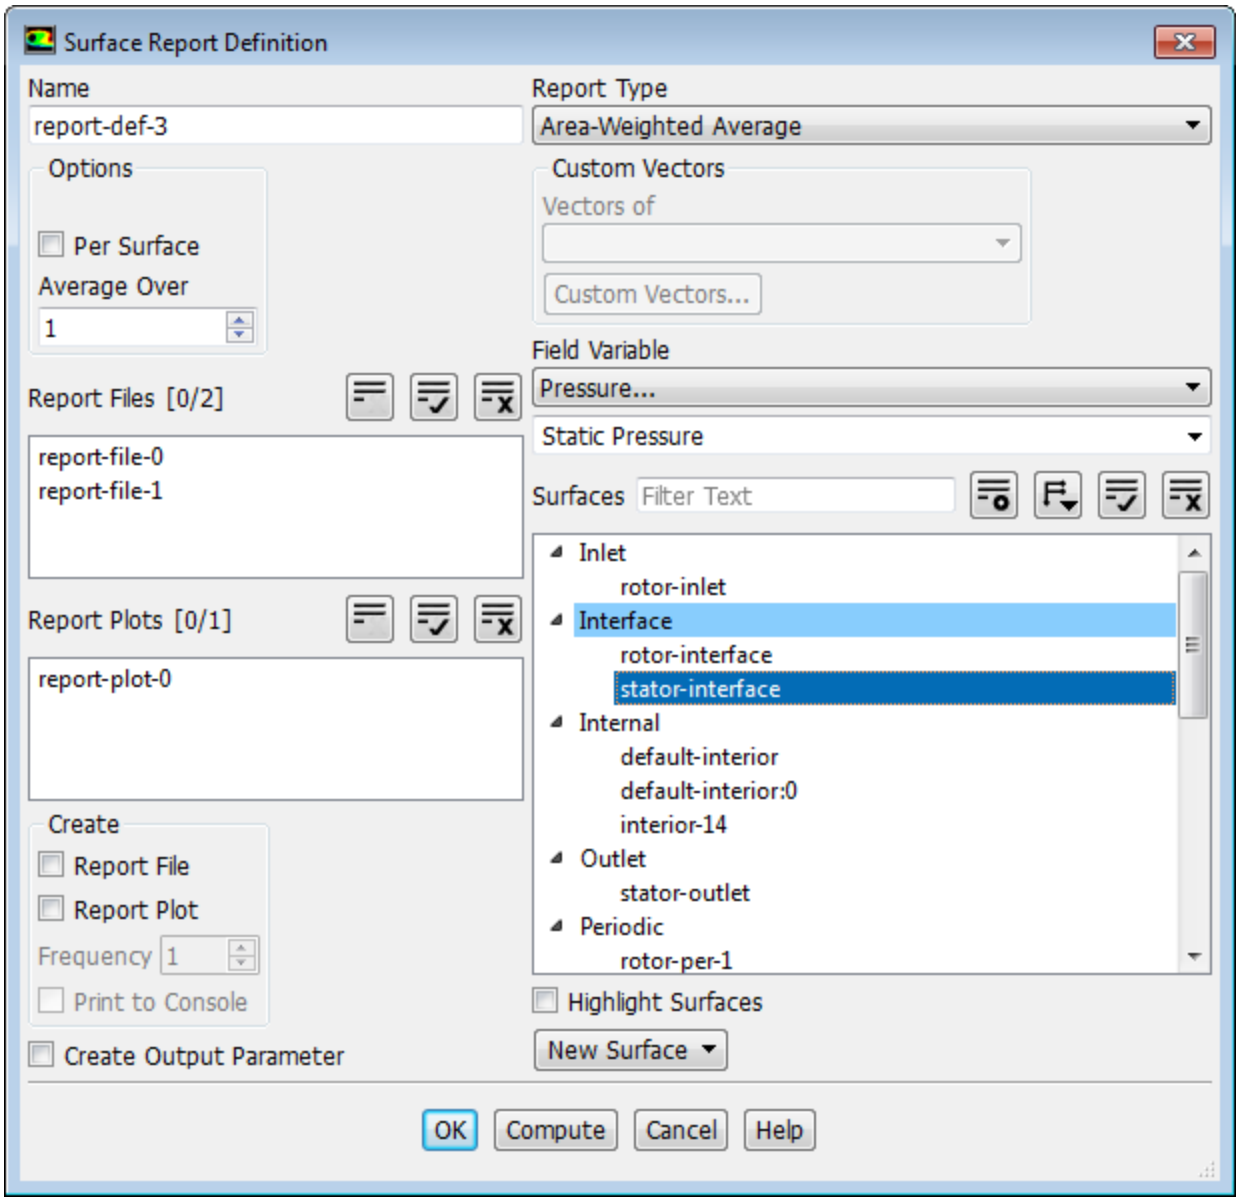
Delete
allows you to delete the selected surfaces under **Surfaces** area.

Display
allows you to display the selected surfaces under **Surfaces**.

38.2.86. Surface Report Definition Dialog Box

Solving → Reports → Definitions → New → Surface Report

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Per Surface
specifies whether or not the chosen field variable is calculated from all of the selected surfaces combined (default) or individually on each of the selected surfaces.

Average Over
(optional) To have Fluent calculate a running average for the **Surface Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Report Type
selects the integration method used on the selected surfaces. The available report types are the same as those in the Surface Integrals Dialog Box (p. 2616). See Surface Integration (p. 1920) for details.

Custom Vectors
allows you to specify a vector if you selected **Custom Vector Based Flux**, **Custom Vector Flux** or **Custom Vector Weighted Average** from the **Report Type** drop-down list.

Field Variable
contains a list of solution variables that can be monitored on the selected surfaces. This list will not be available if you select **Mass Flow Rate** or **Volume Flow Rate** as the **Report Type**.

Phase
contains a list of all of the phases in the problem that you have defined. This is available when the VOF, mixture, or Eulerian multiphase model is enabled.

Surfaces
contains a selectable list of the current surfaces.

Highlight Surfaces
if enabled, this option displays the selected surface(s) in the graphics window.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

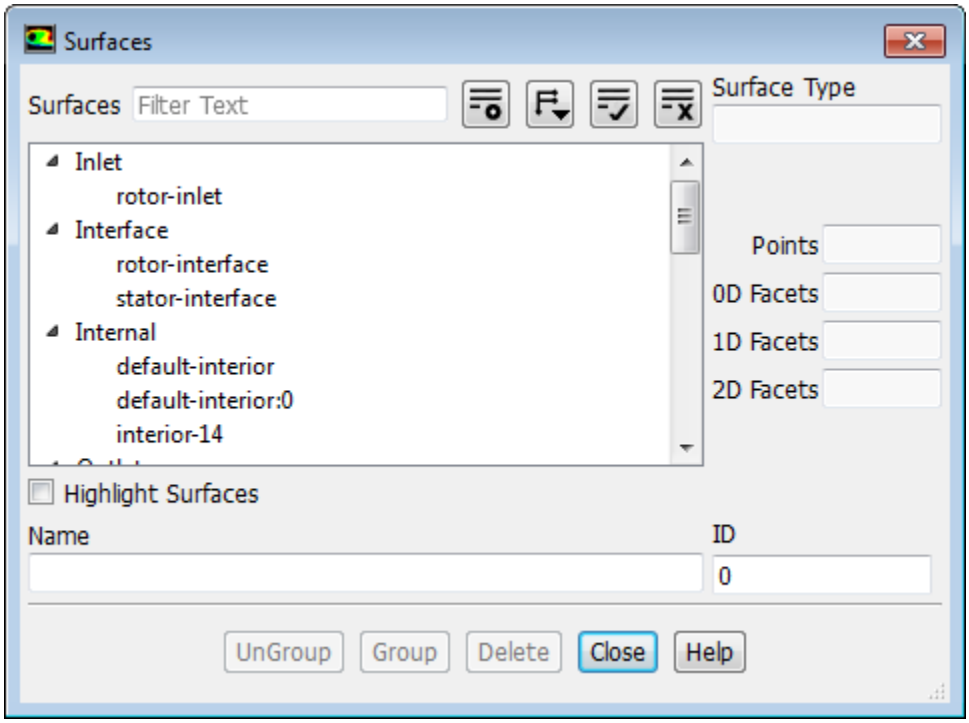
Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

OK
creates the report definition.

Compute
computes the value of the report definition at the selected surface(s) and prints to the console.

38.2.87. Surfaces Dialog Box

The **Surfaces** dialog box allows you to interactively group, rename, and delete surfaces and obtain information about their components. See Grouping, Renaming, and Deleting Surfaces (p. 1734) for details about the items below.



Controls

Surfaces
contains a list of existing surfaces from which you can select the surface(s) of interest.

Name
displays the name of the selected surface. You can edit the text field to modify the surface name. (If more than one surface is selected, the name of the first one you selected will be displayed.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surface Type
displays the type of surface that is selected (for example, `zone-surf` if one surface is selected, or `Multiple Surfaces` if more than one surface is selected).

Points, 0D Facets, 1D Facets,
and **2D Facets** display the number of points and facets in the selected surface. If more than one surface is selected, the sum over all selected surfaces is displayed for each quantity.

Note that if you want to check these statistics for a surface that was read from a case file, you will need to first display it.

Highlight Surfaces
when enabled highlights the surfaces (selected in the **Surfaces** dialog box) in the graphics window.

ID
displays the ID of the selected surface. You cannot change this value.

UnGroup
ungroups the selected surface. This button is available only if the selected surface was created by **Group**ing two or more surfaces together.

Rename
renames the selected surface in **Surfaces** with the name specified in **Name**. This button is available when just one surface is selected. (If two or more surfaces are selected, it becomes the **Group** button.)

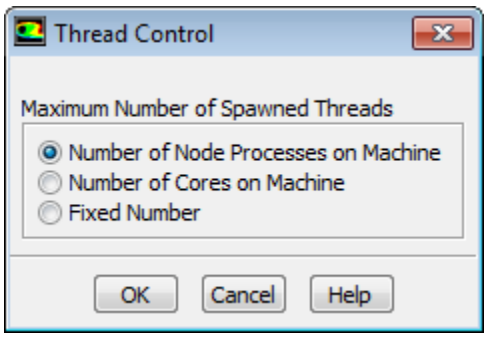
Group
groups two or more selected surfaces and gives the group the name entered in **Name**. This button replaces the **Rename** button when two or more surfaces are selected.

Delete
deletes the selected surface(s).

38.2.88. Thread Control Dialog Box

The **Thread Control** dialog box allows you to control the maximum number of threads on each machine, as described in Controlling the Threads (p. 2058).

Parallel → General → Thread Control...



Controls

Maximum Number of Spawned Threads
contains a list of options for defining the maximum number of threads on each machine.

Number of Node Processes on Machine
specifies that the maximum number of threads on each machine is equal to the number of ANSYS Fluent node processes on each machine.

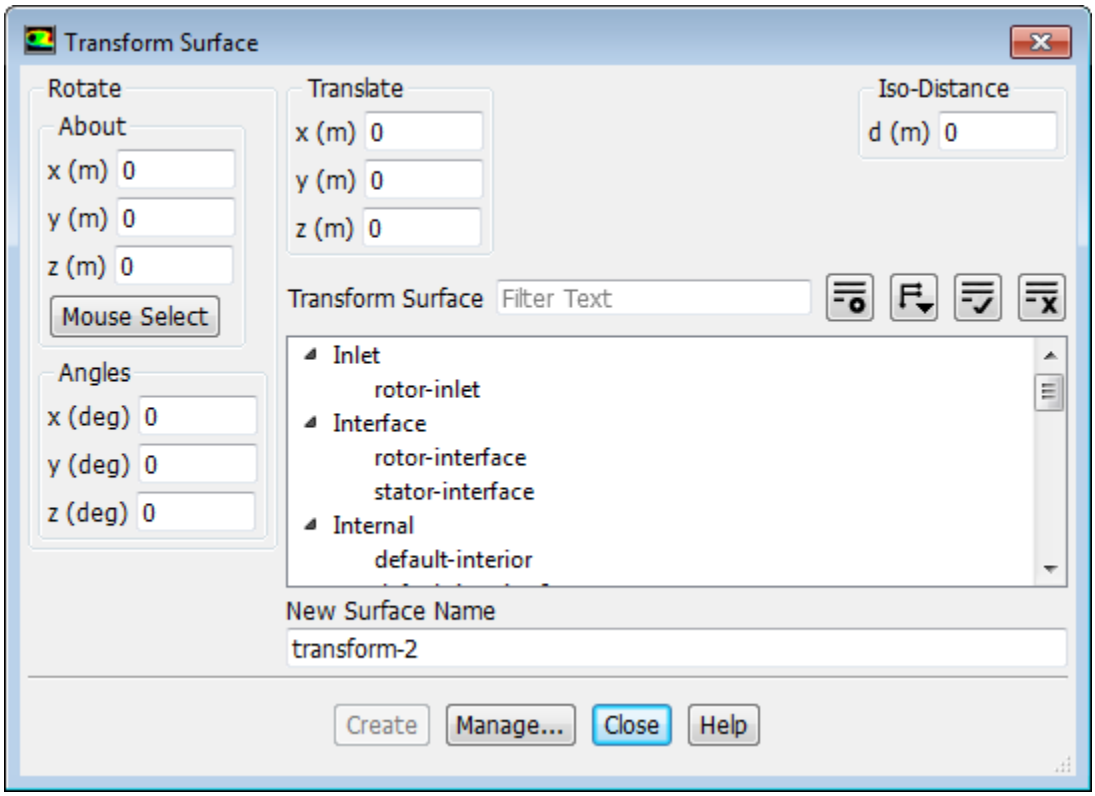
Number of Cores on Machine
specifies that the maximum number of threads on each machine is equal to the number of cores on the machine. ANSYS Fluent obtains the number of cores from the OS.

Fixed Number
specifies that the maximum number of threads that can be spawned on each machine is equal to the number you provide in the number-entry box below **Fixed Number**.

38.2.89. Transform Surface Dialog Box

The **Transform Surface** dialog box allows you to create a new data surface by rotating and/or translating an existing surface, and/or by specifying a constant normal distance from it. See Transforming Surfaces (p. 1732) for details about the items below.

Setting Up Domain → Surface → Create → Transform...



Controls

Rotate
contains the transformation parameters for rotation.

About
defines the origin about which the surface is rotated. You will specify a point, and the origin of the coordinate system for the rotation will be set to the specified point. For example, if you specified the point (1,0) in 2D, rotation would be about the z axis anchored at (1,0). You can either enter the point's

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coordinates in the **x,y,z** fields or click the **Mouse Select** button and select a point in the graphics window using the mouse.

Angles
define the angles about the **x**, **y**, and **z** axes (that is, the axes of the coordinate system with the origin defined under **About**) by which the surface is rotated. For 2D problems, you can specify rotation about the **z** axis only.

Translate
contains the transformation parameters for translation.

x,y,z
define the distance by which the surface is translated in each direction.

Iso-Distance
contains the transformation parameters for "isodistancing."

d
sets the normal distance between the original surface and the transformed surface.

Transform Surface
contains a list of existing surfaces from which you can select the surface to be transformed. The selected surface will remain unchanged; the transformation will create a new surface.

New Surface Name
designates the name of the new surface. The default is the concatenation of the transformation type (that is, iso-distance, rotate, or translate) and an integer which is the new surface ID.

Create
creates the surface.

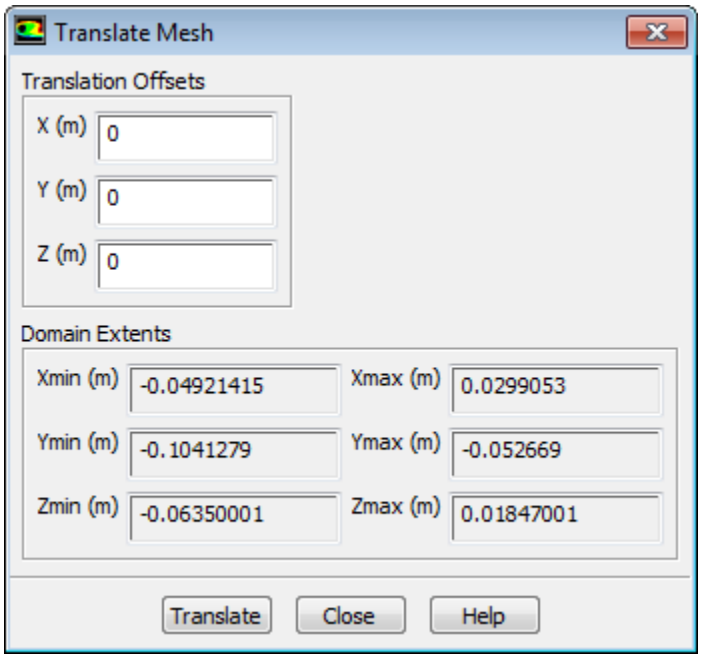
Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

38.2.90. Translate Mesh Dialog Box

The **Translate Mesh** dialog box allows you to change the origin of the mesh. See Translating the Mesh (p. 228) for details.

Setting Up Domain → Mesh → Transform → Translate...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Translation Offsets

contains the desired changes in the mesh coordinates (that is, the desired delta in the axes origin). You can enter a positive or negative real number.

X,Y,Z

defines the deltas in the x, y, and z directions, in the current units of length.

Domain Extents

displays the Cartesian coordinate extremes of the nodes in the mesh. (These values are not editable; they are purely informational.)

Xmin, Ymin, Zmin

shows the minimum values of Cartesian coordinates in the mesh.

Xmax, Ymax, Zmax

shows the maximum values of Cartesian coordinates in the mesh.

Translate

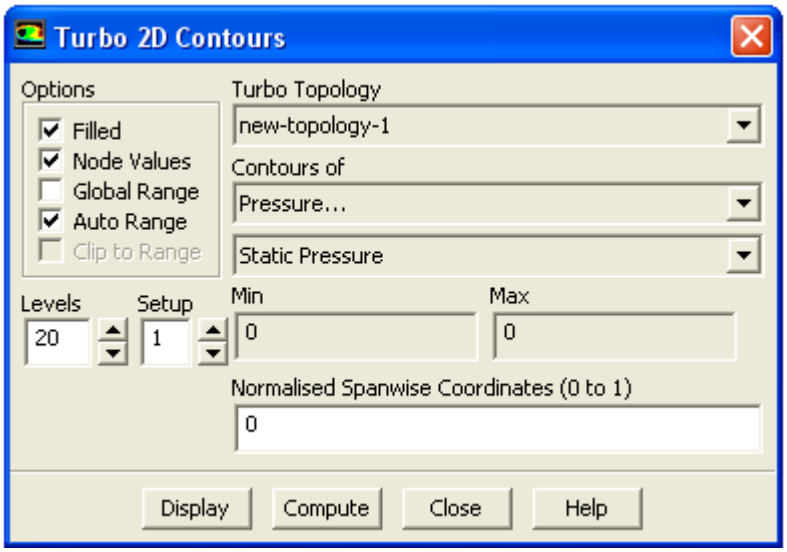
adds the specified translation offsets to the appropriate Cartesian coordinate of every node in the mesh.

38.2.91. Turbo 2D Contours Dialog Box

The **Turbo 2D Contours** dialog box enables you to display turbomachinery-specific contours of variables on surfaces of constant pitchwise, spanwise, or meridional coordinates, projected onto a plane. See Displaying Turbomachinery 2D Contours (p. 1869) for details.

Postprocessing → Model Specific → Turbo Topology → 2D Contours...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Turbo Topology
contains a list of defined topologies. Select from the list to display the values for the selected topology.

Options
contains the check buttons that set various contour display options.

Filled
toggles between filled contours and line contours.

Node Values
toggles between using scalar field values at nodes and at cell centers for computing the contours.

Global Range
toggles between basing the minimum and maximum values on the range of values on the selected surfaces (off), and basing them on the range of values in the entire domain (on, the default).

Auto Range
toggles between automatic and manual setting of the contour range. Any time you change the **Contours of** selection, **Auto Range** is reset to on.

Clip to Range
determines whether or not values outside the prescribed **Min**/ **Max** range are contoured when using **Filled** contours. If selected, values outside the range will not be contoured. If not selected, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. See Specifying the Range of Magnitudes Displayed (p. 1759) for details.

Levels
sets the number of contour levels that are displayed.

Setup
indicates the ID number of the contour setup. For frequently used combinations of contour fields and options, you can store the information needed to generate the contour plot by specifying a **Setup** number and setting up the desired information in the dialog box. See Storing Contour Plot Settings (p. 1762) for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Contours of
contains a list from which you can select the scalar field to be contoured.

Min
shows the minimum value of the scalar field. If **Auto Range** is off, you can set the minimum by typing a new value.

Max
shows the maximum value of the scalar field. If **Auto Range** is off, you can set the maximum by typing a new value.

Normalised Spanwise Coordinates (0 to 1)
enables you to specify the coordinate for the spanwise surface you want to create.

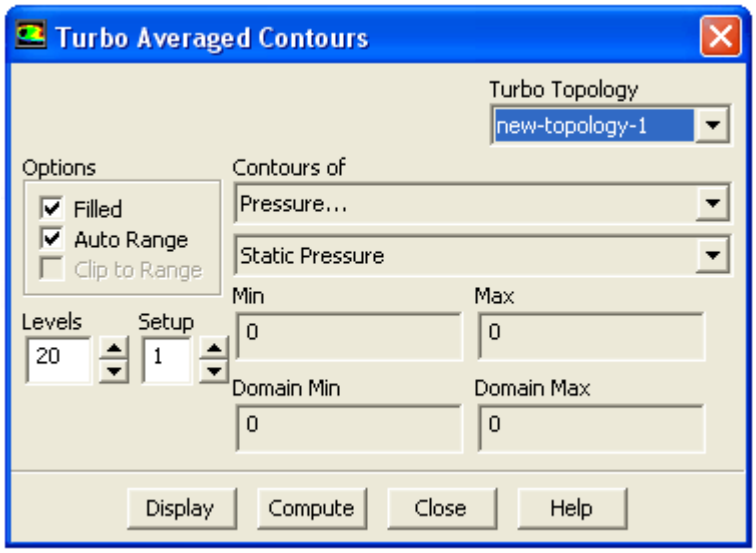
Display
draws the contours in the active graphics window.

Compute
calculates the scalar field and updates the **Min** and **Max** values (even when **Auto Range** is off).

38.2.92. Turbo Averaged Contours Dialog Box

The **Turbo Averaged Contours** dialog box enables you to display turbomachinery-specific circumferentially averaged contours of variables projected on an r- z plane. See Displaying Turbomachinery Averaged Contours (p. 1867) for details.

Postprocessing → Model Specific → Turbo Topology → Averaged Contours...



Controls

Turbo Topology
contains a list of defined topologies. Select from the list to display the values for the selected topology.

Options
contains the check buttons that set various contour display options.

Filled
toggles between filled contours and line contours.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Auto Range
toggles between automatic and manual setting of the contour range. Any time you change the **Contours of** selection, **Auto Range** is reset to on.

Clip to Range
determines whether or not values outside the prescribed **Min**/ **Max** range are contoured when using **Filled** contours. If selected, values outside the range will not be contoured. If not selected, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. See Specifying the Range of Magnitudes Displayed (p. 1759) for details.

Levels
sets the number of contour levels that are displayed.

Setup
indicates the ID number of the contour setup. For frequently used combinations of contour fields and options, you can store the information needed to generate the contour plot by specifying a **Setup** number and setting up the desired information in the dialog box. See Storing Contour Plot Settings (p. 1762) for details.

Contours of
contains a list from which you can select the scalar field to be contoured.

Min
shows the minimum value of the scalar field. If **Auto Range** is off, you can set the minimum by typing a new value.

Max
shows the maximum value of the scalar field. If **Auto Range** is off, you can set the maximum by typing a new value.

Domain Min
shows the global minimum value of the scalar field for the entire domain.

Domain Max
shows the global maximum value of the scalar field for the entire domain.

Display
draws the contours in the active graphics window.

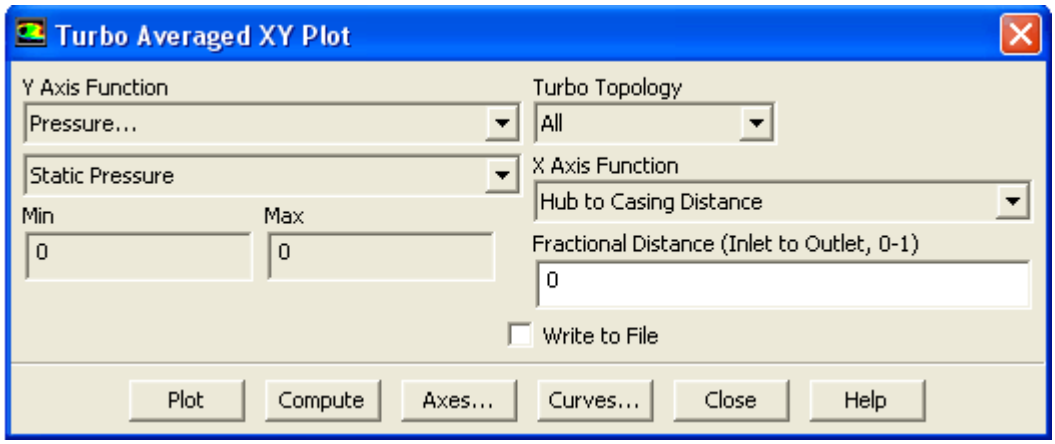
Compute
calculates the scalar field and updates the **Min** and **Max** values (even when **Auto Range** is off).

38.2.93. Turbo Averaged XY Plot Dialog Box

The **Turbo Averaged XY Plot** dialog box enables you to display data in an XY plot format as a function of either the meridional or the spanwise coordinate. See Generating Averaged XY Plots of Turbomachinery Solution Data (p. 1871) for details.

Postprocessing → Model Specific → Turbo Topology → Averaged XY Plot...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Y Axis Function
contains a list of solution variables that can be used for the y axis of the plot.

Min
shows the minimum value of the scalar field.

Max
shows the maximum value of the scalar field.

Turbo Topology
contains a list of defined topologies. Select from the list to display the values for the selected topology.

X Axis Function
enables you to select the coordinate to be used for the x axis of the plot. The choices are **Hub to Casing Distance** (spanwise coordinate), and **Meridional Distance** (meridional coordinate).

Fractional Distance
sets a fractional value (0 to 1) for either the spanwise **Hub to Casing** distance or the meridional **Inlet to Outlet** distance, depending on your selection for **X Axis Function**.

Write to File
enables the file-writing option. When this option is selected, the **Plot** button will change to **Write...**. Clicking on the **Write...** button will open The Select File Dialog Box (p. 19), in which you can specify a name and save a file containing the plot data. The format of this file is described in XY Plot File Format (p. 1850).

Plot
plots the specified surface and/or file data in the active graphics window using the current axis and curve attributes. If the **Write to File** option is turned on, this button becomes the **Write...** button.

Write...
opens The Select File Dialog Box (p. 19), in which you can save the plot data to a file. This button replaces the **Plot** button when the **Write to File** option is turned on.

Compute
calculates the scalar field and updates the **Min** and **Max** values.

Axes...
opens the Axes Dialog Box (p. 2608), which enables you to customize the plot axes.

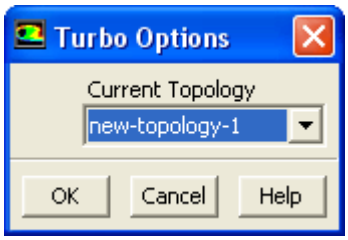
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Curves...
opens the Curves Dialog Box (p. 2610), which enables you to customize the curves used in the XY plot.

38.2.94. Turbo Options Dialog Box

The **Turbo Options** dialog box enables you to globally set the turbomachinery topology for your model. See Globally Setting the Turbomachinery Topology (p. 1872) for details.

Postprocessing → Model Specific → Turbo Topology → Options...



Controls

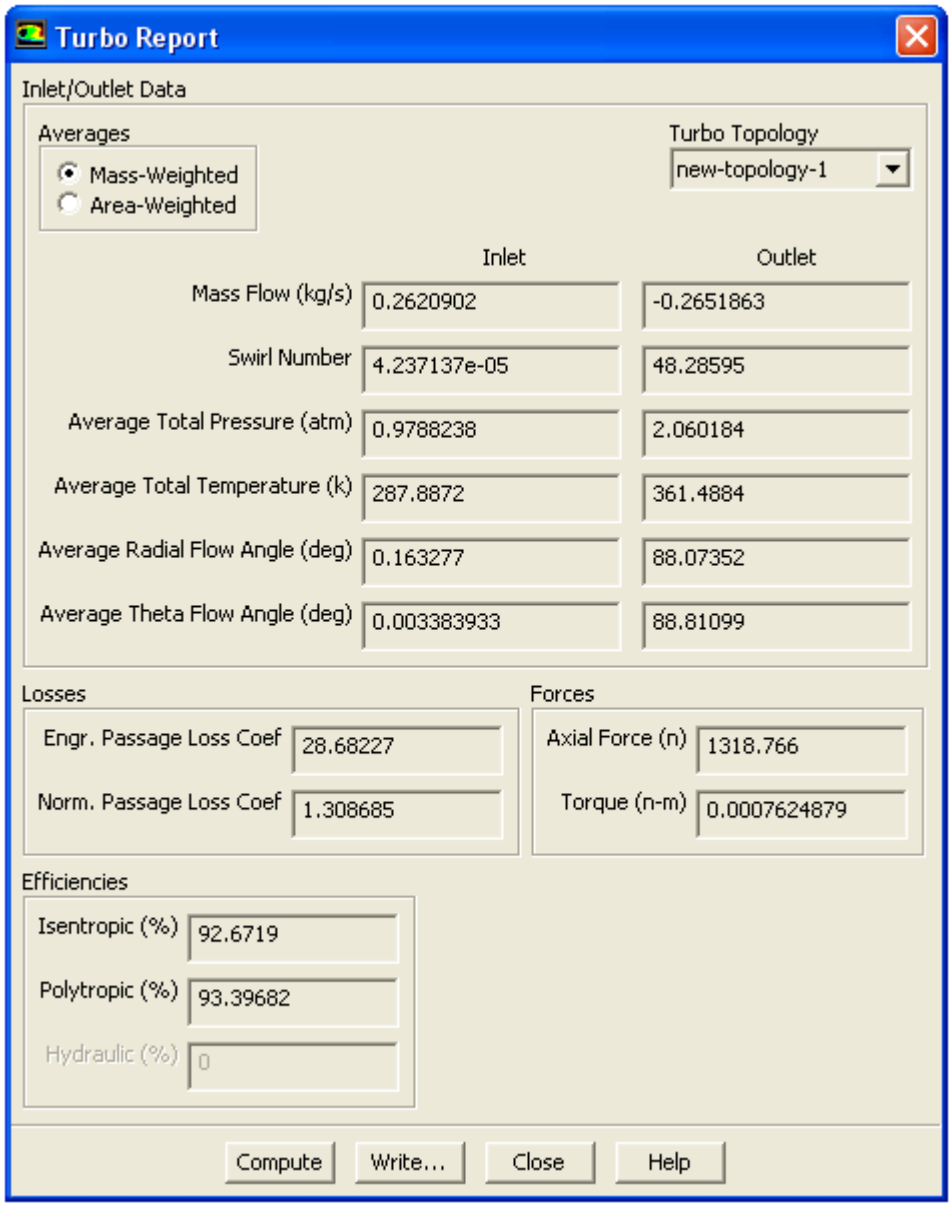
Current Topology
contains a list of predefined turbo topologies.

38.2.95. Turbo Report Dialog Box

The **Turbo Report** dialog box allows you to calculate turbomachinery-specific quantities and integrals. See Generating Reports of Turbomachinery Data (p. 1859) for details.

Postprocessing → Model Specific → Turbo Topology → Report...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Inlet/Outlet Data

contains quantities that can be calculated at inlets and outlets.

Averages

allows you to choose between **Mass-Weighted** and **Area-Weighted** averages for all applicable computed quantities. These quantities are calculated for the **Inlet** and **Outlet** topologies where applicable.

Turbo Topology

contains a list of defined topologies. Select from the list to display the values for the selected topology.

Mass Flow

is the mass flow rate through a surface as defined in Equation 31.2 (p. 1861).

Swirl Number

is the swirl number as defined in Equation 31.3 (p. 1861).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Average Total Pressure
is the area-averaged or mass-averaged total pressure as defined in Equation 31.4 (p. 1861) or Equation 31.5 (p. 1861).

Average Total Temperature
is the area-averaged or mass-averaged total temperature as defined in Equation 31.6 (p. 1862) or Equation 31.7 (p. 1862).

Average Radial Flow Angle
is the area-averaged or mass-averaged radial flow angle as defined in Equation 31.8 (p. 1862) or Equation 31.10 (p. 1863).

Average Theta Flow Angle
is the area-averaged or mass-averaged tangential flow angle as defined in Equation 31.9 (p. 1862) or Equation 31.11 (p. 1863).

Losses
contains the values of loss-related coefficients.

Engr. Passage Loss Coef
is the engineering loss coefficient as defined in Equation 31.12 (p. 1863).

Norm. Passage Loss Coef
is the normalized loss coefficient as defined in Equation 31.13 (p. 1863).

Forces
contains the axial force and the torque on the rotating parts.

Axial Force
is the axial force on the rotating parts as defined in Equation 31.14 (p. 1863).

Torque
is the torque on the rotating parts as defined in Equation 31.15 (p. 1864).

Efficiencies
contains the values of isentropic, polytropic and hydraulic efficiencies.

Isentropic
is the isentropic efficiency for a compressor or a turbine (motor) calculated in the presence of a compressible working fluid as defined in Equation 31.20 (p. 1865) or Equation 31.26 (p. 1867).

Polytropic
is the polytropic efficiency for a compressor or a turbine (motor) calculated in the presence of a compressible working fluid as defined in Equation 31.21 (p. 1866) or Equation 31.27 (p. 1867).

Hydraulic
is the hydraulic efficiency for a pump or a hydraulic turbine (motor) calculated in the presence of an incompressible working fluid as defined in Equation 31.16 (p. 1864) or Equation 31.22 (p. 1866).

Compute
starts the calculation of the quantities in all the fields in the **Turbo Report** dialog box. Note that this process may take some time for a large problem.

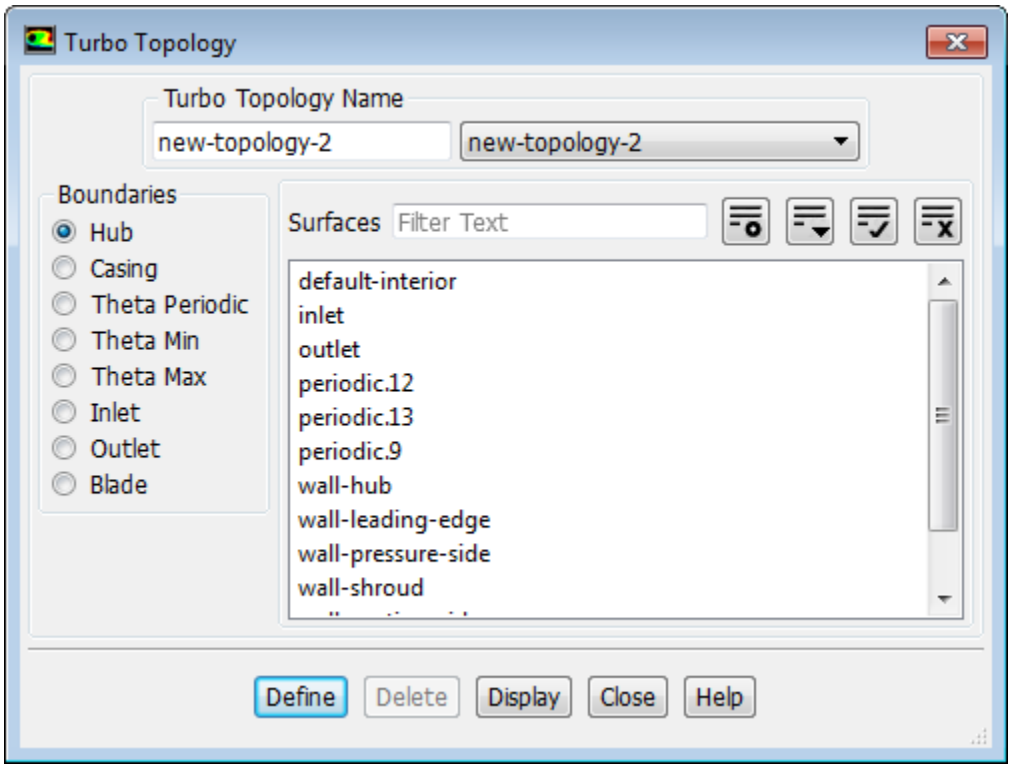
Write...
opens the **Select File** dialog box, which you can use to save the reported values to a file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.96. Turbo Topology Dialog Box

The **Turbo Topology** dialog box allows you to define the topology for a turbomachinery application, so that you can use the turbomachinery-specific postprocessing features described in Turbomachinery Postprocessing (p. 1856). See Defining the Turbomachinery Topology (p. 1856) for details about the items below.

Setting Up Domain → Mesh Models → Turbo Topology...



Controls

Turbo Topology Name
specifies the name of the new topology.

Boundaries
contains radio buttons for the topology boundaries to be defined.

Hub
specifies the definition for the wall zone(s) forming the lower boundary of the flow passage (generally toward the axis of rotation of the machine).

Casing
specifies the definition of the wall zone(s) forming the upper boundary of the flow passage (away from the axis of rotation of the machine).

Theta Periodic
specifies the definition of the periodic boundary zone(s) on the circumferential boundaries of the flow passage.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Theta Min, Theta Max
specify the definition of the wall zones at the minimum and maximum angular (θ) positions on a circumferential boundary.

Inlet
specifies the definition of the inlet zone(s) through which the flow enters the passage.

Outlet
specifies the definition of the outlet zone(s) through which the flow exits the passage.

Blade
specifies the definition of the wall zone(s) that defines the blade(s) (if any). Note that these zones cannot be attached to the circumferential boundaries. For this situation, use **Theta Min** and **Theta Max** to define the blade.

Surfaces
contains a selectable list of the available surfaces, from which you can select the surface(s) that represent the boundary selected under **Boundaries**.

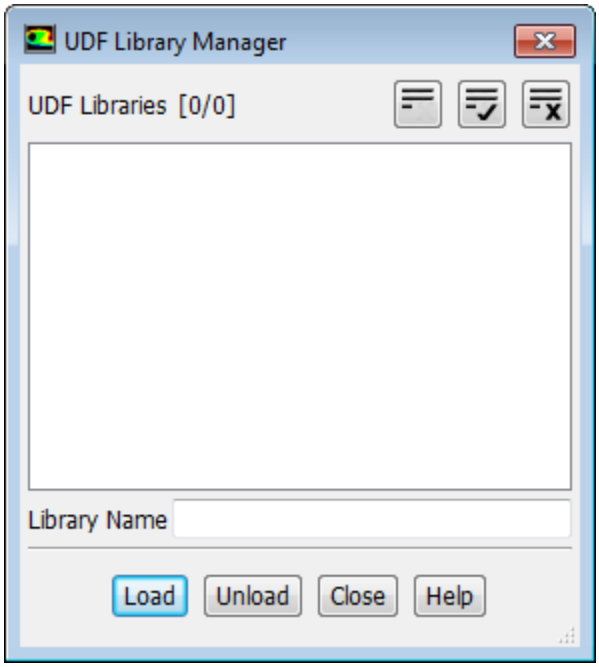
Define
defines the new topology. If you have selected an existing topology the **Define** button is replaced by the **Modify** button.

Display
draws the defined topology in the active graphics window.

38.2.97. UDF Library Manager Dialog Box

The **UDF Library Manager** dialog box allows you to load/unload the user-defined function libraries. See the separate Fluent Customization Manual for details.

User Defined → User Defined → Functions → Manage...



Controls

UDF Libraries
lists the user-defined function libraries that are loaded in ANSYS Fluent.

Library Name
specifies the name of the library to be loaded/unloaded.

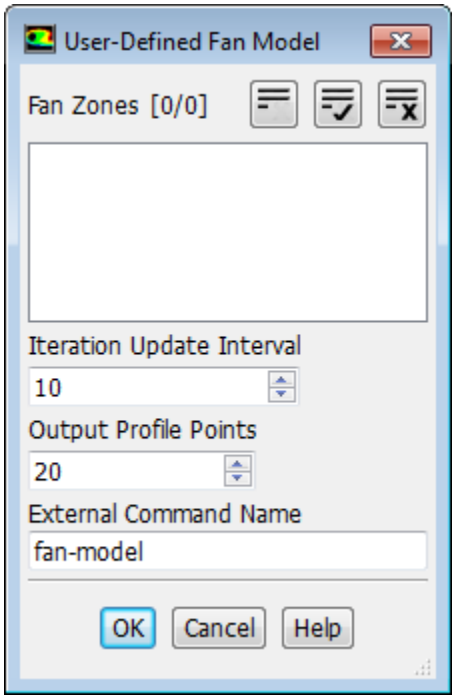
Load
opens the specified library and loads the user-defined function.

Unload
unloads the specified library.

38.2.98. User-Defined Fan Model Dialog Box

The **User-Defined Fan Model** dialog box allows you to periodically regenerate a profile file that can be used to specify the characteristics of a fan, including pressure jump across the fan, and radial and swirling components of velocity generated by the fan. See User-Defined Fan Model (p. 427) for details about this feature and how to use this dialog box.

User Defined → **Model Specific** → **Fan Model...**



Controls

Fan Zones
contains a list from which you can select the fan zone(s) on which your executable will operate.

Iteration Update Interval
specifies how often the executable will be called on to update the fan profile file.

Output Profile Points
specifies the number of points in the profile file to be written by ANSYS Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

External Command Name
specifies the name of the executable.

38.2.99. User-Defined Function Hooks Dialog Box

The **User-Defined Function Hooks** dialog box allows you to specify user-defined functions (UDFs) connected to a number of models and procedures in ANSYS Fluent. See the separate Fluent Customization Manual for details.

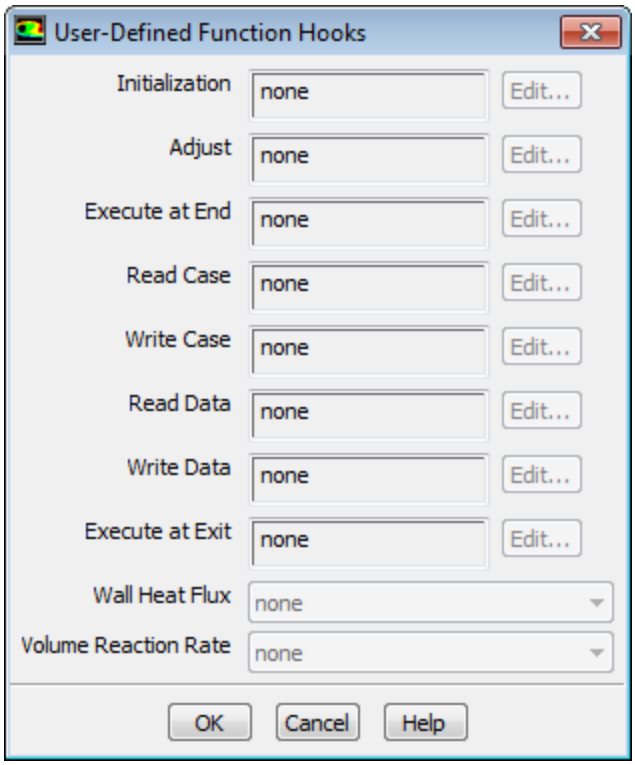
Important

You can hook multiple UDFs to the following functions:

- **Controls**
- **Initialization**
- **Adjust**
- **Execute At End**
- **Read Case**
- **Write Case**
- **Read Data**
- **Write Data**
- **Execute at Exit**

User Defined → **User Defined** → **Function Hooks...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Initialization
selects a UDF that is called immediately after you initialize your flow field.

Adjust
selects a UDF that is called at the beginning of an iteration before solution of velocities, pressure, and other quantities begins.

Execute At End
selects a UDF that is called at the end of an iteration or time-step.

Read Case
selects a UDF that defines a customized section that is to be read from the case file.

Write Case
selects a UDF that defines a customized section that is to be written to the case file.

Read Data
selects a UDF that defines a customized section that is to be read from the data file.

Write Data
selects a UDF that defines a customized section that is to be written to the data file.

Execute at Exit
selects a UDF that is called when exiting an ANSYS Fluent session.

Wall Heat Flux
selects a UDF that modifies the way that the solver computes the heat flux between a wall and the neighboring fluid cells.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Net Reaction Rate
selects a UDF that defines the net reaction rate.

Volume Reaction Rate
selects a UDF that defines a volumetric reaction rate.

Surface Reaction Rate
selects a UDF that defines a surface reaction rate.

Particle Reaction Rate
selects a UDF that defines a particle reaction rate.

Turbulent Premixed Source
selects a UDF that defines the turbulent flame speed and source term for the premixed or partially premixed combustion model.

Chemistry Step
selects a UDF that defines the chemistry step function.

Spray Collide
selects a UDF that defines the spray collide function.

Cavitation Mass Rate
selects a UDF that defines the cavitation rate.

DO Source
selects a UDF that defines the discrete ordinate source function.

DO Diffuse Reflectivity
selects a UDF that defines the diffuse reflectivity function for the DO radiation model.

DO Specular Reflectivity
selects a UDF that defines the specular reflectivity function for the DO radiation model.

Emissivity Weighting Factor
selects a UDF that defines the emissivity weighting factor for the non-gray DO radiation model or the non-gray P-1 radiation model.

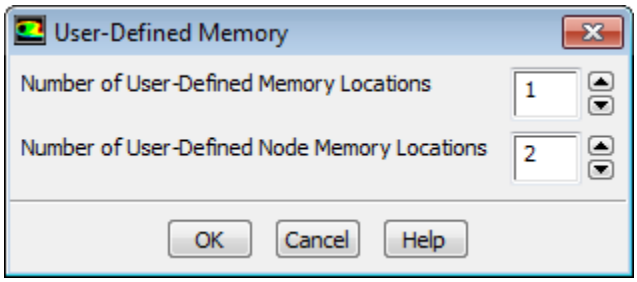
Thickened Flame Model Parameters
selects a UDF that defines the parameters for the Thickened Flame Model.

38.2.100. User-Defined Memory Dialog Box

The **User-Defined Memory** dialog box allows you to allocate memory for user-defined storage variables. See the separate Fluent Customization Manual for details.

User Defined → **User Defined** → **Memory...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of User-Defined Memory Locations
specifies the number of memory locations to be allocated.

Number of User-Defined Node Memory Locations
specifies the number of node memory locations to be allocated.

Important

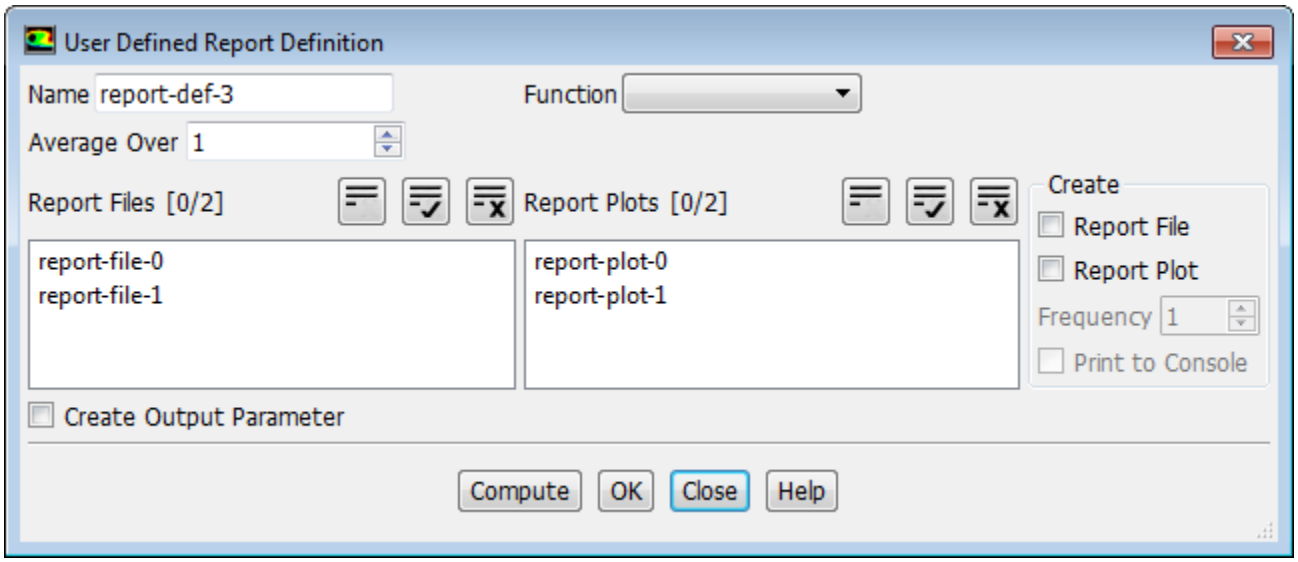
For postprocessing **User-Defined Memory** in CFD-Post, the ANSYS Fluent user must select the UDM quantities using the **Data File Quantities** option and subsequently write the data file to postprocess the quantities in ANSYS Fluent. Alternatively, you have the option of exporting the desired quantities to a `.cdat` file. This will ensure that all the UDM quantities are available for postprocessing in CFD-Post. Refer to the ANSYS CFD-Post manual for more information.

38.2.101. User Defined Report Definition Dialog Box

Solving → Reports → Definitions → New → User Defined...

or

Solution → Report Definitions → New → User Defined



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Function
drop-down list where you can select the function that you loaded for this report definition.

Average Over
(optional) To have Fluent calculate a running average for the **User Defined Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

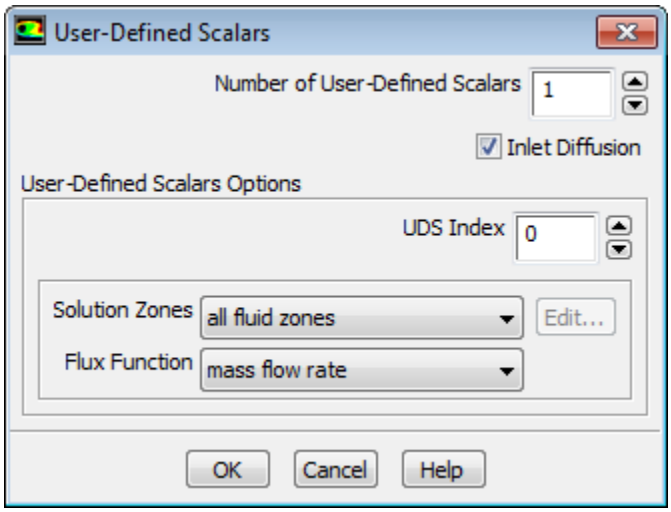
Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

38.2.102. User-Defined Scalars Dialog Box

The **User-Defined Scalars** dialog box allows you to include user-defined scalar transport equations in your calculation. See User-Defined Scalar (UDS) Transport Equations (p. 573) for details.

User Defined → **User Defined** → **Scalars...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Number of User-Defined Scalars
specifies how many additional scalar transport equations you would like to include in the calculation.

Inlet Diffusion
when enabled allows you to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.

User-Defined Scalars Options
contains settings that define the scalar transport equation.

UDS Index
when set to 0 marks the first user-defined scalar equation.

Solution Zones
specifies in which zone the scalar equation will be solved: **all fluid zones**, **all solid zones**, **all zones** (fluid and solid) or **selected zones**.

Flux Function
is a drop-down list containing available functions for the convection term of the user-defined scalar transport equation(s).

none
(the default) indicates that there is no convection term included in the scalar transport equation(s); that is, you want to solve a Poisson equation instead of a convection/diffusion equation.

mass flow rate
indicates that the convection term in the scalar transport equation(s) is equal to the mass flow rate $\rho\vec{v}\cdot\vec{A}$.

Note that the **none** and **mass flow rate** options will apply to all solved user-defined scalars. A user-defined flux function must be supplied if a different convective flux is desired for each user-defined scalar.

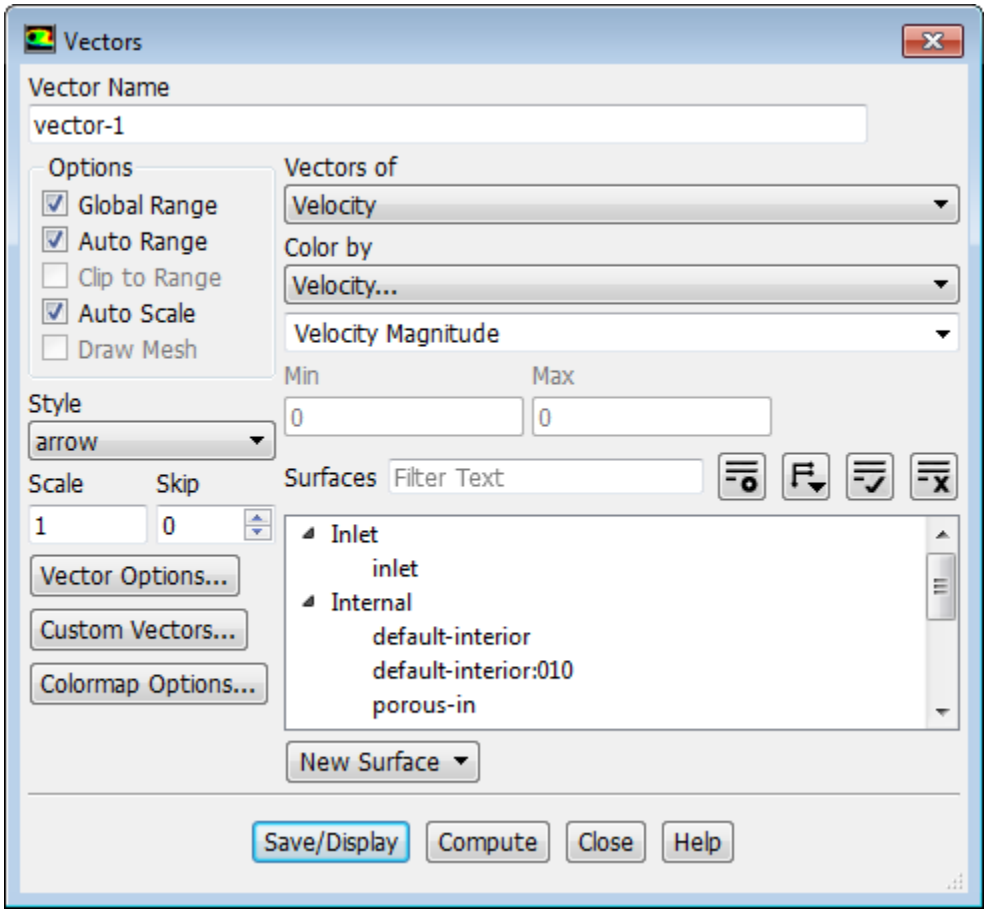
Unsteady Function
is a drop-down list containing available functions for the unsteady term of the user-defined scalar transport equation(s).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

38.2.103. Vectors Dialog Box

The **Vectors** dialog box controls the display of vector plots. See Displaying Vectors (p. 1764) for details about the items below.

Postprocessing → Graphics → Vectors → New...



Controls

Vector Name
is the name for a vector plot definition. You can specify a name or use the default name **vector-*id***. This control appears only for vector plot definitions.

Options
contains check buttons that set various display options.

Global Range
toggles between basing the minimum and maximum values on the range of values on the selected surfaces (off), and basing them on the range of values in the entire domain (on, the default).

Auto Range
toggles between automatic and manual setting of the range of scalar field values.

Clip to Range
controls the display of vectors that have a value outside the range specified by **Min** and **Max**. When on, no vectors are displayed outside the range. When off, vectors are displayed outside the range using

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the colors at the top and bottom of the color scale. This option is applicable only when **Auto Range** is off. See Specifying the Range of Magnitudes Displayed (p. 1768) for details.

Auto Scale
enables the scaling of all vectors in the domain such that when the **Scale** is 1, there will be minimal overlap of vectors.

Draw Mesh
toggles between displaying and not displaying the mesh. The Mesh Display Dialog Box (p. 2163) is opened when **Draw Mesh** is selected.

Style
selects the style in which the vectors are drawn. Available styles are **cone**, **filled-arrow**, **arrow**, **harpoon**, and **headless**.

Scale
sets the factor by which the vectors should be scaled. See Scaling the Vectors (p. 1766) for details.

Skip
allows you to "thin" or "sample" the vectors that are displayed. See Skipping Vectors (p. 1767) for details.

Vector Options...
opens the Vector Options Dialog Box (p. 2557), in which you can set additional options for vector displays. (This button is not available for vector plot definitions.)

Custom Vectors...
opens the Custom Vectors Dialog Box (p. 2558), in which you can define your own vector fields.

Vectors of
contains a list from which you can select the vector field to be plotted.

Color by
contains a list from which you can select the scalar field by which the vectors are colored.

Min
shows the value to which the lower end of the color scale is mapped. You can set this value manually if **Auto Range** is off.

Max
shows the value to which the upper end of the color scale is mapped. You can set this value manually if **Auto Range** is off.

Surfaces
contains a list from which you can select the surfaces on which to display vectors. In 2D, vectors are displayed on the entire domain if no surface is selected.

New Surface
is a drop-down list button that contains a list of surface options:

Point
opens the Point Surface Dialog Box (p. 2780).

Line/Rake
opens the Line/Rake Surface Dialog Box (p. 2727).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Plane
opens the Plane Surface Dialog Box (p. 2777).

Quadric
opens the Quadric Surface Dialog Box (p. 2781).

Iso-Surface
opens the Iso-Surface Dialog Box (p. 2721).

Iso-Clip
opens the Iso-Clip Dialog Box (p. 2720).

Display
draws the vectors in the active graphics window.

Compute
calculates the scalar field and updates the **Min** and **Max** values (even when **Auto Range** is off).

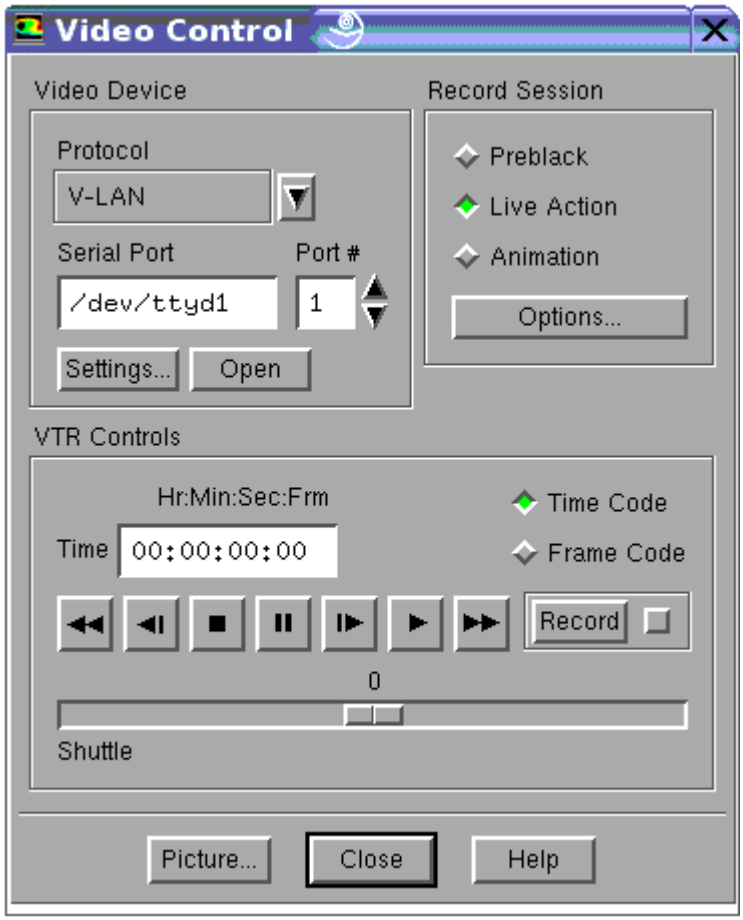
Save/Display
plots the vectors in the active graphics window and saves the vector plot definition. This button appears only for vector plot definitions and replaces the **Display** button.

38.2.104. Video Control Dialog Box

The **Video Control** dialog box is used to record animations or live action to video. When recording animations to video, you must first create your animation (see Creating an Animation (p. 1826)). The **Video Control** dialog box will play your animation and control a videotape recorder (VTR) to record it to video. See Creating Videos (p. 1829) for details about using the video tools.

The **Video Control** dialog box is opened from the Animate Dialog Box (p. 2567).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Video Device

sets up the connection to the VTR control hardware.

Protocol

specifies the command protocol that identifies your VTR controller. ANSYS Fluent currently supports the following VTR controllers:

V-LAN

Machine Control Network is a command protocol developed by Videomedia, Inc. and supported by several videotape editing systems.

MiniVAS

is the command protocol for the MiniVAS and MiniVAS-2 VTR controllers developed by the V.A.S. Group.

To be able to control the video recording from ANSYS Fluent, your VTR controller must use one of these protocols.

Serial Port

identifies the name of the serial port to which your VTR controller is connected.

Port #

is a convenient way of changing the port number associated with the serial port.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Settings...
displays a dialog box that provides options specific to your VTR controller. If your VTR controller protocol is V-LAN, the V-LAN Settings Dialog Box (p. 2836) is displayed; if the protocol is MiniVAS, the MiniVAS Settings Dialog Box (p. 2742) is displayed.

Open
will open a connection to your VTR controller. Once the connection is open, the name of this button will be changed to **Close** so that you can close the connection again.

Record Session
specifies the type of recording you want to perform.

Preblack
is the process of formatting a tape by laying down a time code onto the tape. A tape must be formatted before any frame accurate editing, including frame-by-frame animation, can be performed. During this process, one usually records a black video signal onto the tape as well, thus the name "preblack". When you select this option the current graphics window will be cleared to black. You can use the window to send your black video signal to the VTR. Remember, when you preblack a previously formatted tape, a new time code will be written and any previously recorded video will be destroyed.

Live Action
allows you to record a live ANSYS Fluent session that can be used for demonstration. This option requires your computer's video hardware to have a scan converter that will send the computer display image to your VTR system.

Animation
will play an animation that you have created, and record it onto your VTR system.

Options...
displays the Animation Recording Options Dialog Box (p. 2668), which provides options for recording your animation.

VTR Controls
function like the controls on your VTR's front dialog box.

Time
is a counter that provides input/output of the current tape position. It will update automatically when the tape is repositioned. If you type a new time in this field and press **Enter**, the VTR will go to that position on the tape. For time code, the format is Hrs:Min:Sec:Frames, where the number of frames can range between 0 and 29. For example, a time code of `00:02:36:07` is 2 minutes, 36 seconds, and 7 frames. In order to go to this position on the tape, you can enter the time code as `2:36:07`, leaving out the leading zeros, or you can simply enter `23607`, leaving out the leading zeros and colons. If you select the **Frame Code** radio button, the tape position will be displayed in frames instead of time.

Record
will begin a recording session starting at the current position on the tape. If **Preblack** has been selected as the recording session, the label of this button will be changed to **Preblack**.

Push Button Controls
enable you to operate the VTR's tape transport.

<< rewinds the tape.

<| reverses the tape by one frame.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

[ ] places the tape in stop mode.

| | places the tape in pause mode.

|> advances the tape by one frame.

> plays the tape at normal speed.

>> advances the tape in fast-forward mode.

Shuttle
allows you to advance (or reverse) the tape at varying speeds. When you move the shuttle to the right, the tape will be advanced; when you move it to the left, the tape will be reversed. The shuttle speed index ranges from -9 to 9. A speed index of 5 is equivalent to playing the tape at normal speed. A speed index of 0 is equivalent placing the tape in pause mode.

Counter Format
allows you to change the counter units displayed in the **Time/Frame** counter.

Time Code
when selected, displays the tape position as time code.

Frame Code
when selected, displays the tape position as frame code.

This format is for display/user-input purposes only and does not change the actual tape counter format.

Picture...
displays the Picture Options Dialog Box (p. 2776), which provides options for setting the picture size and color levels in the graphics window.

38.2.105. V-LAN Settings Dialog Box

The **V-LAN Settings** dialog box allows you to set specific V-LAN options.

The **V-LAN Settings** dialog box is opened by clicking the **Settings...** button in the Video Control Dialog Box (p. 2833), after you have selected V-LAN as your video device protocol.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

V-LAN Node

identifies the node number of the VTR. This is always 1, unless you have several video devices connected to a V-LAN network, in which case, the VTR you want to use may be identified by another node number.

VTR Video Format

identifies the video format standard to which your VTR conforms. This setting is used to determine the video frame rate (frames/sec).

NTSC

(National Television Standards Committee) is the main video standard used in North America and Japan. The video frame rate is 30 frames/sec.

PAL

(Phase Alternate Line) is the video standard used by some countries in Western Europe, Asia, and Australia. The video frame rate is 25 frames/sec.

Preroll/Postroll

specifies the preroll and postroll times in seconds. These are used when performing **Edit** records, including frame-by-frame animation recording, to make sure the tape is moving at the proper speed through the recorded segment.

Preroll

is the number of seconds the tape will play up to the record in point.

Postroll

is the number of seconds the tape will play past the record out point.

The default settings should be sufficient for most VTR devices.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Live/Real-Time Recording
specifies the type of recording that will be performed during a live action or real-time animation recording session.

Quick Record
can be performed on a tape that has not been formatted or "preblacked". This is also known as "full record". Remember that this option will destroy any pre-existing time code on the tape.

Edit (Preblacked Tape Required)
is used for more precise recording. This mode allows you to record several back-to-back recordings with clean transitions between them.

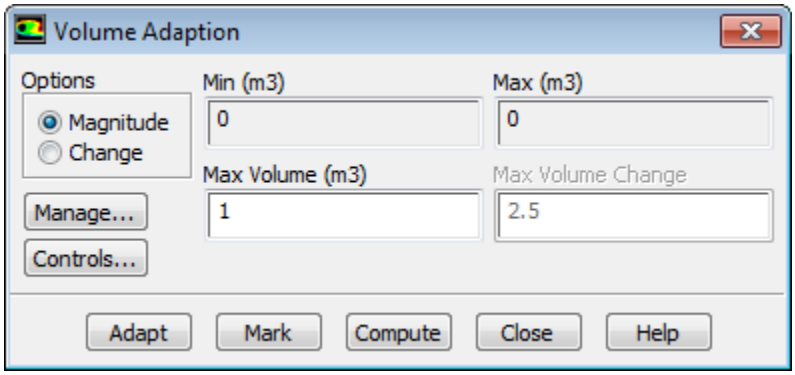
For frame-by-frame animation recording, the record mode used is **Edit** regardless of this setting.

Verbose Mode
enables the echoing of each V-LAN command as it is sent to the V-LAN controller.

38.2.106. Volume Adaption Dialog Box

The **Volume Adaption** dialog box allows you to mark or refine cells based on cell volume or change in cell volume. See Volume Adaption (p. 1694) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Volume...



Controls

Options
allows you to specify that the marking and/or refining is based on volume magnitude or volume change.

Magnitude
enables the marking/refining of cells based on volume magnitude.

Change
enables the marking/refining of cells based on the change in volume.

Min
displays the minimum value of cell volume or cell volume change in the mesh. This value is not editable.

Max
displays the maximum value of cell volume or cell volume change in the mesh. This value is not editable.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Max Volume
defines the threshold value for marking/refining the mesh based on volume magnitude. Cells that have volumes greater than the threshold are marked for refinement.

Max Volume Change
defines the threshold value for marking/refining the mesh based on the change in volume. Cells with volume changes that are greater than the threshold value are marked for refinement.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Adapt
refines the mesh based on either the maximum volume or the volume change, and the adaption limits.

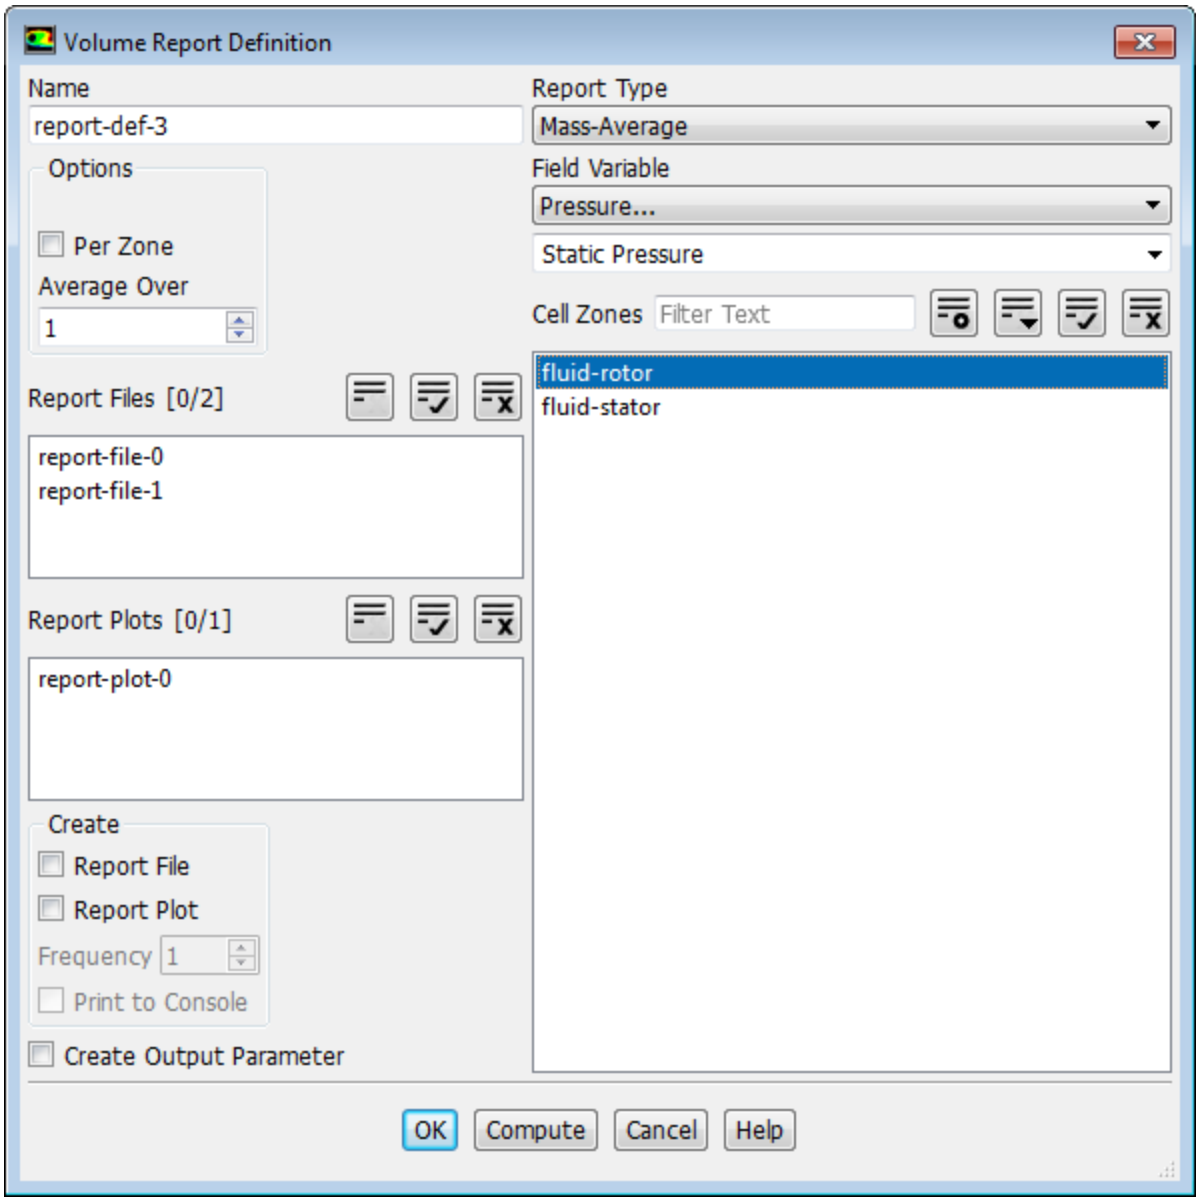
Mark
marks cells to be refined based on either the maximum volume or the volume change. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

Compute
calculates the minimum and maximum cell volume or cell volume change and displays them in the **Min** and **Max** real number fields.

38.2.107. Volume Report Definition Dialog Box

Solving → **Reports** → **Definitions** → **New** → **Volume Report**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options

Per Zone
specifies whether or not the chosen field variable is calculated from all of the selected cell zones combined (default) or individually on each of the selected cell zones.

Average Over
(optional) To have Fluent calculate a running average for the **Volume Report Definition** you can enter a positive integer greater than 1 (the default) for **Average Over**.

Specifying a number greater than 1 means that Fluent will print, plot, and write the running average value of the selected variable instead of the current value of the same variable.

The value reported is averaged over the last N *iterations/time steps, where* N *is your specified* ***Average Over*** *value. When the iteration/time step number is lower than* N*, Fluent calculates the average of the available variable values.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Report Files
lists all of the report files where you can write the report definition data.

Report Plots
lists all of the report plots where you can plot the report definition data (assuming this report has the same units as the other report definitions included in the selected report plot).

Create

Report File
creates a new report file that includes this report definition.

Report Plot
creates a new report plot that includes this report definition.

Frequency
specifies how frequently the report definition is written, plotted, or printed to the console.

Print to Console
prints the value of the report definition to the console.

Create Output Parameter
creates an output parameter for this report definition with the name `<report definition name>-op`.

Report Type
selects the integration method used on the selected cell zones. The available report types are the same as those in the Volume Integrals Dialog Box (p. 2620). See Volume Integration (p. 1922) for details.

Field Variable
contains a list of solution variables that can be monitored on the selected cell zones. This list will not be available if you select **Volume** as the **Report Type**.

Phase
contains a list of all of the phases in the problem that you have defined. This is available when the VOF, mixture, or Eulerian multiphase model is enabled.

Cell Zones
contains a selectable list of the current cell zones.

OK
creates the report definition.

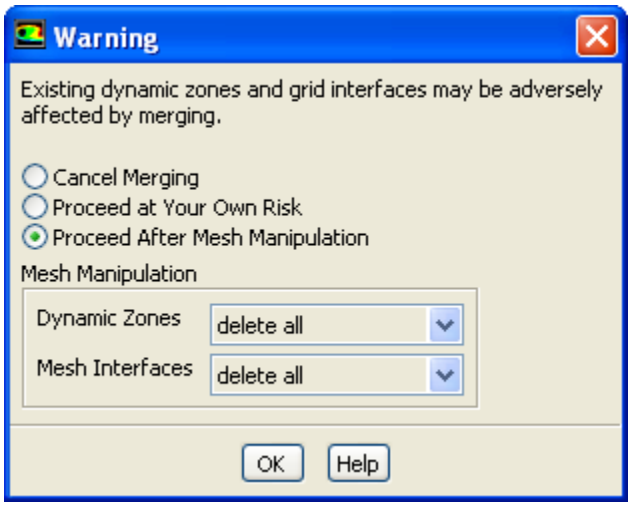
Compute
computes the value of the report definition at the selected zone(s) and prints to the console.

38.2.108. Warning Dialog Box

The **Warning** dialog box allows you to specify whether existing dynamic zones and/or mesh interfaces are deleted when you are using the **Merge Zones** dialog box to merge multiple zones of the same type into a single zone (see Merge Zones Dialog Box (p. 2730) for details). Note that dynamic zones and mesh interfaces that exist at the time of the merge may be adversely affected by the merge.

The **Warning** dialog box opens automatically when you click **Merge** in the Merge Zones Dialog Box (p. 2730) if your case has dynamic zones or mesh interfaces.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Cancel Merging
returns you to the **Mesh Zones** dialog box when you click **OK**, without initiating the merge.

Proceed at Your Own Risk
allows the merge to proceed when you click **OK**, without deleting the existing dynamic zones and mesh interfaces beforehand.

Proceed After Mesh Manipulation
deletes the existing dynamic zones and/or mesh interfaces (based on the settings in the **Mesh Manipulation** group box) and then merges the zones when you click **OK**.

Mesh Manipulation
allows you to specify whether the existing dynamic zones and/or mesh interfaces are deleted prior to the initiation of the merge. This group box is only available when **Proceed After Mesh Manipulation** is selected.

Dynamic Zones
specifies whether all existing dynamic zones are deleted prior to the merge.

Mesh Interfaces
specifies whether all existing mesh interfaces are deleted prior to the merge.

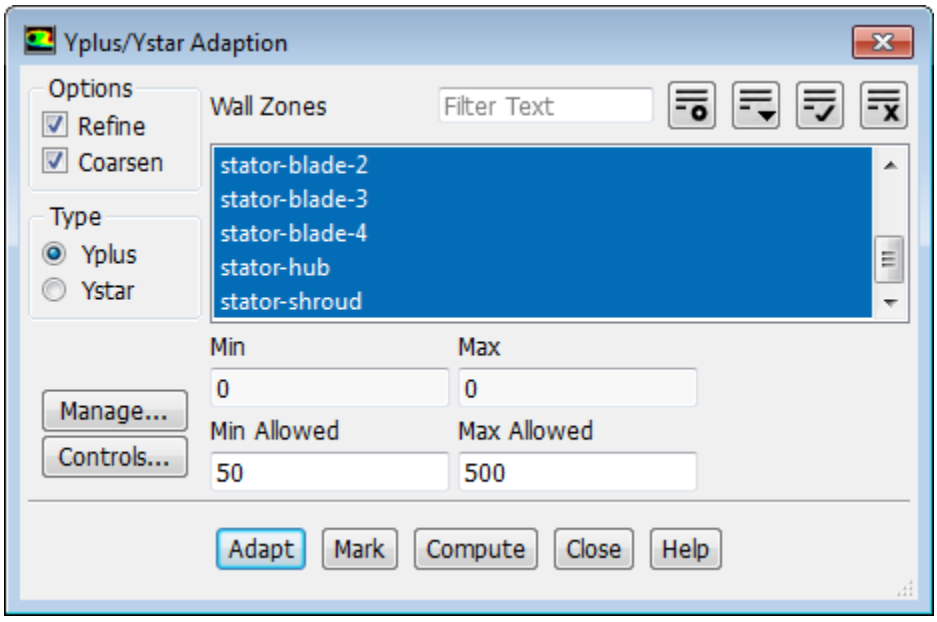
Note that selecting **keep all** from both drop-down lists in the **Mesh Manipulation** group box is the equivalent of selecting **Proceed at Your Own Risk**.

38.2.109. Yplus/Ystar Adaption Dialog Box

The **Yplus/Ystar Adaption** dialog box allows you to mark or adapt boundary cells on specified wall zones based on the non-dimensional y^+ or y^* parameter. See Yplus/Ystar Adaption (p. 1695) for details.

Setting Up Domain → Adapt → Mark/Adapt Cells → Yplus/Ystar...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Controls

Options
contains the check buttons that toggle the ability to mark and/or adapt cells for refinement or coarsening.

Refine
toggles the ability to refine cells or mark cells for refinement.

Coarsen
toggles the ability to coarsen cells or mark cells for coarsening.

Type
contains the check buttons that enable adaption based on y^+ or y^*.

Yplus
enables y^+ adaption.

Ystar
enables y^* adaption.

Wall Zones
contains a selectable list of active wall zones. Boundary cells associated with the wall zones you select will be marked or adapted based on the options, thresholds, and limitations applied in the dialog box.

Min/Max
displays the minimum and maximum cell values of y^+ or y^* for all cells associated with viscous wall zones. Note that these values are independent of the wall zones selected. The real number field values are not editable; they are purely informational.

Min Allowed
designates the threshold value for coarsening the mesh. Cells with y^+ or y^* values below the minimum threshold will be marked for coarsening.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Max Allowed
designates the threshold value for refining the mesh. Cells with y^+ or y^* values above the maximum threshold will be marked for refinement.

Manage...
opens the Manage Adaption Registers Dialog Box (p. 2728), which allows you to display and manipulate adaption registers that are generated using the **Mark** command.

Controls...
opens the Mesh Adaption Controls Dialog Box (p. 2730), which allows you to control certain aspects of the adaption process.

Adapt
adapts the mesh based the coarsening and refining toggle buttons, the wall zones selected, the minimum and maximum y^+ or y^* allowed, and the adaption limits.

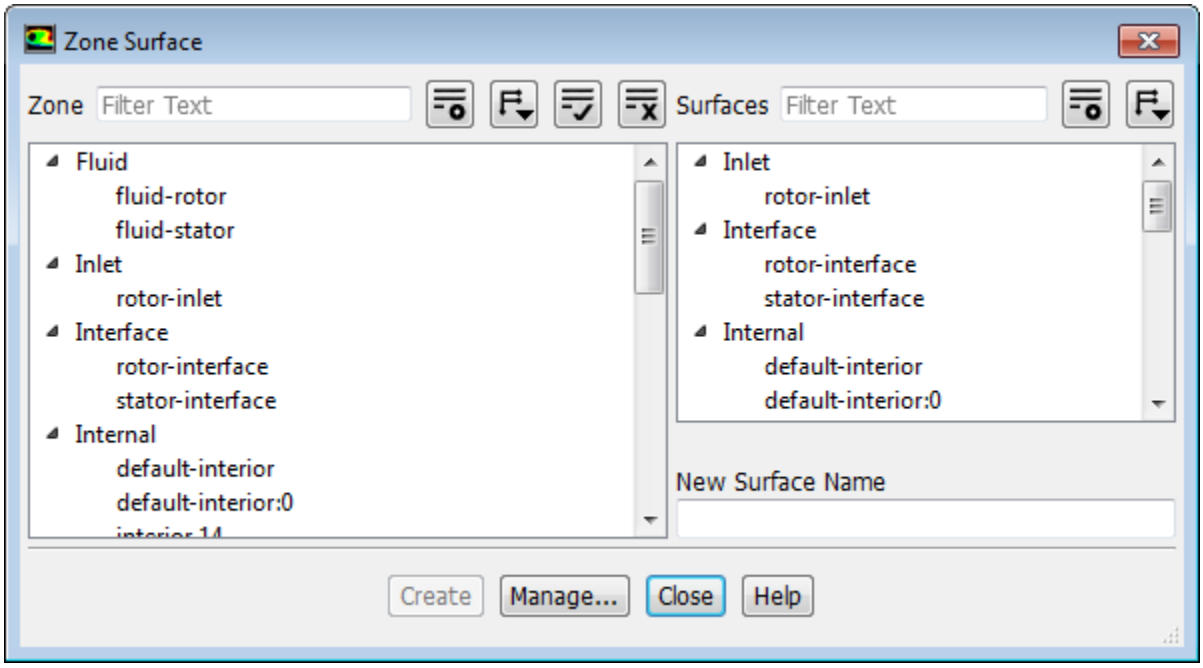
Mark
marks cells to be refined and/or coarsened based on the wall zones selected and the minimum and maximum y^+ or y^* allowed in the mesh. This command produces an adaption register. For information on using adaption registers, see Manipulating Adaption Registers (p. 1701).

Compute
computes the minimum and maximum values of y^+ or y^* on all cells on viscous walls and displays them in the **Min** and **Max** real number fields. Note that these are the extremes for the y^+ or y^* values of every cell on a viscous wall, not just the cells associated with the selected zones.

38.2.110. Zone Surface Dialog Box

The **Zone Surface** dialog box allows you to interactively create surfaces from face and cell zones in the domain. See Zone Surfaces (p. 1710) for details about the items below.

Setting Up Domain → Surface → Create → Zone...



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controls

Zone
lists zones that you can select for creating zone surfaces.

Surfaces
displays an informational list of existing surfaces.

New Surface Name
designates the name of the surface to be created. The default is the zone name.

Create
creates the surface.

Manage...
opens the Surfaces Dialog Box (p. 2810) in which you can rename and delete surfaces and determine their sizes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Appendix A. ANSYS Fluent Model Compatibility

The following tables summarize the compatibility of several ANSYS Fluent model categories:

- Multiphase Models (see Modeling Multiphase Flows (p. 1365))
- Moving Domain Models (See Modeling Flows with Moving Reference Frames (p. 603))
- Turbulence Models (See Modeling Turbulence (p. 749))
- Combustion Models (See Chapters Modeling Species Transport and Finite-Rate Chemistry (p. 957) – Modeling Engine Ignition (p. 1139))

Note that a ✓ indicates that two models are compatible with each other, while the absence of a ✓ indicates that two models are not compatible with each other.

Appendix B. ANSYS Fluent File Formats

This appendix provides information about the following:

B.1. Case and Data File Formats
B.2. Mesh Morpher/Optimizer File Formats
B.3. Shell Conduction Settings File Format
B.4. 3D Fan Curve File Format

B.1. Case and Data File Formats

This section describes the contents and formats of ANSYS Fluent case and data files. After discussing the Guidelines (p. 2851) and Formatting Conventions in Binary and Formatted Files (p. 2851), the section descriptions are grouped according to function:

- Grid Sections (p. 2852) : Creating grids for ANSYS Fluent.
- Other (Non-Grid) Case Sections (p. 2863)
- Data Sections (p. 2865) : Importing solutions into another postprocessor.

The case and data files may contain other sections that are intended for internal use only.

B.1.1. Guidelines

The ANSYS Fluent case and data files are broken into several sections according to the following guidelines:

- Each section is enclosed in parentheses and begins with a decimal integer indicating its type. This integer is different for formatted and binary files (Formatting Conventions in Binary and Formatted Files (p. 2851)).
- All groups of items are enclosed in parentheses. This makes skipping to ends of (sub)sections and parsing them very easy. It also allows for easy and compatible addition of new items in future releases.
- Header information for lists of items is enclosed in separate sets of parentheses preceding the items, and the items are enclosed in their own parentheses.

B.1.2. Formatting Conventions in Binary and Formatted Files

For formatted files, examples of file sections are given in Grid Sections (p. 2852) and Other (Non-Grid) Case Sections (p. 2863). For binary files, the header indices described in this section (for example, `10` for the node section) are preceded by `20` for single-precision binary data, or by `30` for double-precision binary data (for example, `2010` or `3010` instead of `10`). The end of the binary data is indicated by `End of Binary Section 2010` or `End of Binary Section 3010` before the closing parenthesis of the section.

An example with the binary data represented by periods is as follows:

```
(2010 (2 1 2aad 2 3)(
  .
```

```
.
.
)
End of Binary Section 2010)
```

B.1.3. Grid Sections

Grid sections are stored in the case file. A grid file is a subset of a case file, containing only those sections pertaining to the grid. The currently defined grid sections are:

- Comment (See Comment (p. 2852))
- Header (See Header (p. 2853))
- Dimensions (See Dimensions (p. 2853))
- Nodes (See Nodes (p. 2853))
- Periodic Shadow Faces (See Periodic Shadow Faces (p. 2854))
- Cells (See Cells (p. 2855))
- Faces (See Faces (p. 2856))
- Face Tree (See Face Tree (p. 2858))
- Cell Tree (See Cell Tree (p. 2858))
- Interface Face Parents (See Interface Face Parents (p. 2859))

The section ID numbers are indicated in both symbolic and numeric forms. The symbolic representations are available as symbols in a Scheme source file (`xfile.scm`), which is available from ANSYS Inc., or as macros in a C header file (`xfile.h`), which is located in your installation area.

B.1.3.1. Comment

Index:	0
Scheme symbol:	`xf-comment`
C macro:	`XF_COMMENT`
Status:	optional

Comment sections can appear anywhere in the file (except within other sections) as:

```
(0 "comment text")
```

You should precede each long section, or group of related sections, by a comment section explaining what is to follow.

Example:

```
(0 "Variables:")
 (37 (
 (relax-mass-flow 1)
 (default-coefficient ())
 (default-method 0)
 ))
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

B.1.3.2. Header

Index:	1
Scheme symbol:	`xf-header`
C macro:	XF_HEADER
Status:	optional

Header sections can appear anywhere in the file (except within other sections). The following is an example:

```
(0 "fluent18.1.0 build-id: 0")
```

The purpose of this section is to identify the program that wrote the file. Although it can appear anywhere, it is one of the first sections in the file. Additional header sections indicate other programs that may have been used in generating the file. It provides a history mechanism showing where the file came from and how it was processed.

B.1.3.3. Dimensions

Index:	2
Scheme symbol:	`xf-dimension`
C macro:	XF_DIMENSION
Status:	optional

The dimensions of the grid appear as:

```
(2 ND)
```

where ND is 2 or 3. This section is supported as a check that the grid has the appropriate dimension.

B.1.3.4. Nodes

Index:	10
Scheme symbol:	`xf-node`
C macro:	XF_NODE
Status:	required

Format:

```
(10 (zone-id first-index last-index type ND)(
 x1 y1 z1
 x2 y2 z2
 .
 .
 .
 ))
```

- If `zone-id` is zero, this provides the total number of nodes in the grid. `first-index` will then be one, `last-index` will be the total number of nodes *in hexadecimal*, `type` is equal to `1`, `ND` is the dimensionality of the grid, and there are no coordinates following (the parentheses for the coordinates are omitted as well).

  For example: `(10 (0 1 2d5 1 2))`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If zone-id is greater than zero, it indicates the zone to which the nodes belong. first-index and last-index are the indices of the nodes in the zone, *in hexadecimal*. The values of last-index in each zone must be less than or equal to the value in the declaration section. **Type** is always equal to 1.

  ND is an optional argument that indicates the dimensionality of the node data, where ND is 2 or 3.

  If the number of dimensions in the grid is two, as specified by the node header, then only x and y coordinates are present on each line.

The following is an example of a 2D grid:

```
(10 (1 1 2d5 1 2)(
 1.500000e-01 2.500000e-02
 1.625000e-01 1.250000e-02
   .
   .
   .
 1.750000e-01 0.000000e+00
 2.000000e-01 2.500000e-02
 1.875000e-01 1.250000e-02
 ))
```

Because the grid connectivity is composed of integers representing pointers (see Cells and Faces), using hexadecimal conserves space in the file and provides for faster file input and output. The header indices are in hexadecimal so that they match the indices in the bodies of the grid connectivity sections. The zone-id and type are also in hexadecimal for consistency.

B.1.3.5. Periodic Shadow Faces

Index:	18
Scheme symbol:	xf-periodic-face
C macro:	XF_PERIODIC_FACE
Status:	required only for grids with periodic boundaries

This section indicates the pairings of periodic faces on periodic boundaries. Grids without periodic boundaries do not have sections of this type. The format of the section is as follows:

```
(18 (first-index last-index periodic-zone shadow-zone)(
 f00 f01
 f10 f11
 f20 f21
 .
 .
 .
 ))
```

where

first-index = index of the first periodic face pair in the list

last-index = index of the last periodic face pair in the list

periodic-zone = zone ID of the periodic face zone

shadow-zone = zone ID of the corresponding shadow face zone

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These are in hexadecimal format. The indices in the section body (`f*`) refer to the faces on each of the periodic boundaries (in hexadecimal), the indices being offsets into the list of faces for the grid.

Note

In this case, `first-index` and `last-index` do *not* refer to face indices. They refer to indices in the list of periodic pairs.

Example:

```
(18 (1 2b a c) (
 12 1f
 13 21
 ad 1c2
 .
 .
 .
 ))
```

B.1.3.6. Cells

Index:	12
Scheme symbol:	`xf-cell`
C macro:	XF_CELL
Status:	required

The declaration section for cells is similar to that for nodes.

```
(12 (zone-id first-index last-index type element-type))
```

Again, `zone-id` is zero to indicate that it is a declaration of the total number of cells. If `last-index` is zero, then there are no cells in the grid. This is useful when the file contains only a surface mesh to alert ANSYS Fluent that it cannot be used. In a declaration section, the `type` has a value of zero and the `element-type` is not present.

For example,

```
(12 (0 1 3e3 0))
```

It states that there are 3e3 (hexadecimal) = 995 cells in the grid. This declaration section is required and must precede the regular cell sections.

The `element-type` in a regular cell section header indicates the type of cells in the section, as follows:

`element-type`	*description*	*nodes/cell*	*faces/cell*
0	mixed		
1	triangular	3	3
2	tetrahedral	4	4
3	quadrilateral	4	4
4	hexahedral	8	6
5	pyramid	5	5
6	wedge	6	5
7	polyhedral	NN	NF

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where NN and NF will vary, depending on the specific polyhedral cell.

Regular cell sections have no body, but they have a header of the same format where `first-index` and `last-index` indicate the range for the particular zone, `type` indicates whether the cell zone is an active zone (solid or fluid), or inactive zone (currently only parent cells resulting from hanging node adaption). Active zones are represented with `type`=1, while inactive zones are represented with `type`=32.

In the earlier versions of ANSYS Fluent, a distinction was made between solid and fluid zones. This is now determined by properties (that is, material type).

A `type` of zero indicates a dead zone and will be skipped by ANSYS Fluent. If a zone is of mixed type (`element-type`=0), it will have a body that lists the `element-type` of each cell.

Example:

```
(12 (9 1 3d 0 0)(
 1 1 1 3 3 1 1 3 1
 .
 .
 .
 ))
```

Here, there are 3D (hexadecimal) = 61 cells in cell zone 9, of which the first 3 are triangles, the next 2 are quadrilaterals, and so on.

B.1.3.7. Faces

Index:	13
Scheme symbol:	`xf-face`
C macro:	XF_FACE
Status:	required

The format for face sections is as follows:

```
(13 (zone-id first-index last-index bc-type face-type))
```

where

`zone-id` = zone ID of the face section
`first-index` = index of the first face in the list
`last-index` = index of the last face in the list
`bc-type` = ID of the boundary condition represented by the face section
`face-type` = ID of the type(s) of face(s) in the section

The current valid boundary condition types are defined in the following table:

`bc-type`	*description*
2	interior
3	wall
4	pressure-inlet, inlet-vent, intake-fan
5	pressure-outlet, exhaust-fan, outlet-vent

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7	symmetry
8	periodic-shadow
9	pressure-far-field
10	velocity-inlet
12	periodic
14	fan, porous-jump, radiator
20	mass-flow-inlet, mass-flow-outlet
24	interface
31	parent (hanging node)
36	outflow
37	axis

The faces resulting from the intersection of non-conformal grids are placed in a separate face zone, where a factor of 1000 is added to the `bc-type` (for example, 1003 is a wall zone).

The current valid face types are defined in the following table:

`face-type`	*description*	*nodes/face*
0	mixed	
2	linear	2
3	triangular	3
4	quadrilateral	4
5	polygonal	NN

where NN will vary, depending on the specific polygonal face.

A `zone-id` of zero indicates a declaration section, which provides a count of the total number of faces in the file. Such a section omits the `bc-type` and is not followed by a body with further information.

A nonzero `zone-id` indicates a regular face section, and will be followed by a body that contains information about the grid connectivity. Each line of the body will describe one face and will have the following format:

```
n0 n1 n2 c0 c1
```

where,

`n*` = defining nodes (vertices) of the face

`c*` = adjacent cells

This is the format for a 3D grid with a triangular face format. The actual number of nodes depends on the `face-type`. The order of the cell indices is important, and is determined by the right-hand rule: if you curl the fingers of your right hand in the order of the nodes, your thumb will point toward `c0`.

For 2D grids, `n2` is omitted. `c1` is determined by the cross product of two vectors, $\hat{r}$ and $\hat{k}$. The $\hat{r}$ vector extends from `n0` to `n1`, whereas the $\hat{k}$ vector has its origin at `n0` and points out of the grid plane toward the viewer. If you extend your right hand along $\hat{r}$ and curl your fingers in the direction of the angle between $\hat{r}$ and $\hat{k}$, your thumb will point along $\hat{r}\times\hat{k}$ toward `c1`.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the face zone is of mixed type (face-type= 0) or of polygonal type (face-type= 5), each line of the section body will begin with a reference to the number of nodes that make up that particular face, and has the following format:

```
x n0 n1 ... nf c0 c1
```

where,

x = the number of nodes (vertices) of the face

nf = the final node of the face

All cells, faces, and nodes have positive indices. If a face has a cell only on one side, then either c0 or c1 is zero. For files containing only a surface mesh, both these values are zero.

For information on face-node connectivity for various cell types in ANSYS Fluent, refer to Face-Node Connectivity in ANSYS Fluent (p. 121).

B.1.3.8. Face Tree

Index:	59
Scheme symbol:	xf-face-tree
C macro:	XF_FACE_TREE
Status:	only for grids with hanging-node adaption

This section indicates the face hierarchy of the grid containing hanging nodes. The format of the section is as follows:

```
(59 (face-id0 face-id1 parent-zone-id child-zone-id)
(
number-of-kids kid-id-0 kid-id-1 ... kid-id-n
.
.
.
))
```

where,

face-id0 = index of the first parent face in the section

face-id1 = index of the last parent face in the section

parent-zone-id = ID of the zone containing parent faces

child-zone-id = ID of the zone containing children faces

number-of-kids = the number of children of the parent face

kid-id-n = the face IDs of the children

These are in hexadecimal format.

B.1.3.9. Cell Tree

Index:	58
Scheme symbol:	xf-cell-tree
C macro:	XF_CELL_TREE
Status:	only for grids with hanging-node adaption

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This section indicates the cell hierarchy of the grid containing hanging nodes. The format of the section is as follows:

```
(58 (cell-id0 cell-id1 parent-zone-id child-zone-id)
(
number-of-kids kid-id-0 kid-id-1 ... kid-id-n
.
.
.
))
```

where,

`cell-id0` = index of the first parent cell in the section

`cell-id1` = index of the last parent cell in the section

`parent-zone-id` = ID of the zone containing parent cells

`child-zone-id` = ID of the zone containing children cells

`number-of-kids` = the number of children of the parent cell

`kid-id-n` = the cell IDs of the children

These are in hexadecimal format.

B.1.3.10. Interface Face Parents

Index:	61
Scheme symbol:	`xf-face-parents`
C macro:	XF_FACE_PARENTS
Status:	only for grids with non-conformal interfaces

This section indicates the relationship between the intersection faces and original faces. The intersection faces (children) are produced from intersecting two non-conformal surfaces (parents) and are some fraction of the original face. Each child will refer to at least one parent. The format of the section is as follows:

```
(61 (face-id0 face-id1)
(
parent-id-0 parent-id-1
.
.
.
))
```

where,

`face-id0` = index of the first child face in the section

`face-id1` = index of the last child face in the section

`parent-id-*` = index of parent faces

These are in hexadecimal format.

If you set up and save a non-conformal mesh in the solution mode of Fluent and then read it using the meshing mode of Fluent, this section will be skipped; consequently, all the information necessary to

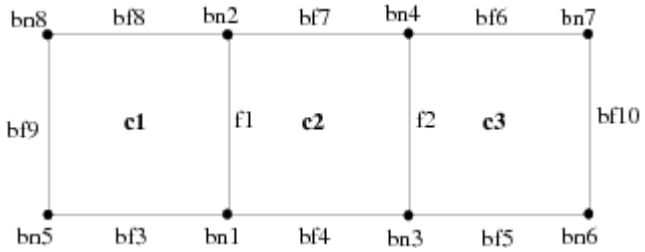
preserve the non-conformal interface will not be maintained. When you switch to or read the mesh back into the solution mode, you will need to recreate the interface.

B.1.3.11. Example Files

B.1.3.11.1. Example 1

Figure 1: Quadrilateral Mesh (p. 2860) illustrates a simple quadrilateral mesh with no periodic boundaries or hanging nodes.

Figure 1: Quadrilateral Mesh



The following describes this mesh:

```

B.1.4. Other (Non-Grid) Case Sections

The following sections store boundary conditions, material properties, and solver control settings.

B.1.4.1. Zone
B.1.4.2. Partitions

B.1.4.1. Zone

Index:	39 or 45
Scheme symbol:	`xf-rp-tv`
C macro:	XF_RP_TV
Status:	required

There is typically one zone section for each zone referenced by the grid. Although some grid zones may not have corresponding zone sections, there cannot be more than one zone section for each zone.

A zone section has the following form:

```
(39 (zone-id zone-type zone-name domain-id)(
(condition1 . value1)
(condition2 . value2)
(condition3 . value3)
.
.
.
 ))
```

Grid generators and other preprocessors need only provide the section header and leave the list of conditions empty, as in

```
(39 (zone-id zone-type zone-name domain-id)())
```

The empty parentheses at the end are required. The solver adds conditions as appropriate, depending on the zone type. When only `zone-id`, `zone-type`, `zone-name`, and `domain-id` are specified, the index 45 is preferred for a zone section. However, the index 39 must be used if boundary conditions

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are present, because any and all remaining information in a section of index 45 after zone-id, zone-type, zone-name, and domain-id will be ignored.

Here the zone-id is in *decimal* format. This is in contrast to the use of hexadecimal in the grid sections.

The zone-type is one of the following:

```
axis
exhaust fan
fan
fluid
inlet vent
intake fan
interface
interior
mass-flow-inlet
mass-flow-outlet
outlet vent
outflow
periodic
porous-jump
pressure-far-field
pressure-inlet
pressure-outlet
radiator
shadow
solid
symmetry
velocity-inlet
wall
```

The interior, fan, porous-jump, and radiator types can be assigned only to zones of faces inside the domain. The interior type is used for the faces within a cell zone; the others are for interior faces that form infinitely thin surfaces within the domain. ANSYS Fluent allows the wall type to be assigned to face zones both on the inside and on the boundaries of the domain. Some zone types are valid only for certain types of grid components. For example, cell (element) zones can be assigned only one of the following types:

```
fluid
 solid
```

All of the other types listed above can be used only for boundary (face) zones.

The zone-name is a user-specified label for the zone. It must be a valid Scheme symbol [1] and is written without quotes. The rules for a valid zone-name (Scheme symbol) are as follows:

- The first character must be a lowercase letter [2] or a special-initial.
- Each subsequent character must be a lowercase letter, a special-initial, a digit, or a special-subsequent.

where a special-initial character is one of the following:

```
! $ % & * / : < = > ? ~ _ ^
```

and a special-subsequent is one of the following:

```
. + -
```

[1] See Revised (4) Report on the Algorithmic Language Scheme, William Clinger and Jonathan Rees (Editors), 2 November 1991, Section 7.1.1.

[2] The Standard actually only requires that case be insignificant; the ANSYS Fluent implementation accomplishes this by converting all uppercase input to lowercase.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Examples of valid zone names are `inlet-port/cold!—, eggs/easy`, and `e=m*c^2`.

Some examples of zone sections produced by grid generators and preprocessors are as follows:

```
(39 (1 fluid fuel 1)())
 (39 (8 pressure-inlet pressure-inlet-8 2)())
 (39 (2 wall wing-skin 3)())
 (39 (3 symmetry mid-plane 1)())
```

The `domain-id` is an integer that appears after the zone name, associating the boundary condition with a particular phase or mixture (sometimes referred to as phase-domains and mixture-domains).

B.1.4.2. Partitions

Index:	40
Scheme symbol:	`xf-partition`
C macro:	`XF_PARTITION`
Status:	only for partitioned grids

This section indicates each cell's partition. The format of the section is as follows:

```
(40 (zone-id first-index last-index partition-count)(
p1
p2
p3
.
.
.
pn
))
```

where,

`p1` = the partition of the cell whose ID is `first-index`

`p2` = the partition of the cell whose ID is `first-index` +1, and so on

`pn` = the partition of the cell whose ID is `last-index`

`partition-count` = the total number of partitions

Partition IDs must be between 0 and one less than `partition-count`.

B.1.5. Data Sections

The following sections store iterations, residuals, and data field values.

B.1.5.1. Grid Size
B.1.5.2. Data Field
B.1.5.3. Residuals

B.1.5.1. Grid Size

Index:	33
Scheme symbol:	`xf-grid-size`
C macro:	`XF_GRID_SIZE`
Status:	optional

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This section indicates the number of cells, faces, and nodes in the grid that corresponds to the data in the file. This information is used to check that the data and grid match. The format is

```
(33 (n-elements n-faces n-nodes))
```

where the integers are written in decimal.

B.1.5.2. Data Field

Index:	300
Scheme symbol:	`xf-rf-seg-data`
C macro:	XF_RF_SEG_DATA
Status:	required

This section lists a flow field solution variable for a cell or face zone. The data are stored in the same order as the cells or faces in the case file. Separate sections are written out for each variable for each face or cell zone on which the variable is stored. The format is

```
(300 (sub-section-id zone-id size n-time-levels
 n-phases first-id last-id)
 ( data for cell or face with id = first-id
 data-for-cell-or-face with id = first-id+1
 ..
 data-for-cell-or-face with id = last-id
 ))
```

where `sub-section-id` is a (decimal) integer that identifies the variable field (for example, 1 for pressure, 2 for velocity). The complete list of these is available in the header file (`xfile.h`), which is located in your installation area.

where,

`zone-id` = the ID number of the cell or face zone

`size` = the length of the variable vector

`zone-id` matches the ID used in case file. `size` is 1 for a scalar, 2 or 3 for a vector, equal to the number of species for variables defined for each species). `n-time-levels` currently are not used.

A sample data file section for the velocity field in a cell zone for a steady-state, single-phase, 2D problem is shown below:

```
(300 (2 16 2 0 0 17 100)
(8.08462024e-01 8.11823010e-02
 8.78750622e-01 3.15509699e-02
 1.06139672e+00 -3.74040119e-02
...
 1.33301604e+00 -5.04243895e-02
 6.21703446e-01 -2.46118382e-02
 4.41687912e-01 -1.27046436e-01
 1.03528820e-01 -1.01711005e-01
 ))
```

The variables that are listed in the data file depend on the models active at the time the file is written. Variables that are required by the solver based on the current model settings but are missing from the data file are set to their default values when the data file is read. Any extra variables that are present in the data file but are not relevant according to current model settings are ignored.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

B.1.5.3. Residuals

Index:	302
Scheme symbol:	`xf-rf-scaled-residuals`
C macro:	XF_RF_SCALED_RESIDUALS
Status:	optional

This section lists the values of the residuals for a particular data field variable at each iteration:

```
(302 (n residual-section-id size domain-id)
(
iteration_number unscaled_residual scaling_factor
 .
 .
 .
 ))
```

where,

n = the number of residuals

`size` = the length of the variable vector

`residual-section-id` = an integer (decimal) indicating the equation

`domain-id` = domain ID

`size` is 1 for a scalar, 2 or 3 for a vector, equal to the number of species for variables defined for each species. The `residual-section-id` indicates the equation for which the residual is stored in the section, according to the C constants defined in a header file (`xfile.h`) available in your installation area, as noted in Grid Sections (p. 2852).

The equations for which residuals are listed in the data file depend on the models active at the time the file is written. If the residual history is missing from the data file for a currently active equation, it is initialized with zeros.

B.2. Mesh Morpher/Optimizer File Formats

This section describes the format of the ASCII text files that can be used as part of the setup for the mesh morpher/optimizer, as described in Using the Mesh Morpher/Optimizer (p. 2125).

The following is an example of a file that can be read or written from the Define Control Points Dialog Box (p. 2685):

```
Control Point Positions
CP No.        X            Y             Z
1             0.73398191   -0.048181638  5.0344162
2             0.51003051   0.52833155    5.100265
3             0.10806149   0.72560567    5.1306067
4             -0.37284759  0.62890923    5.1368165
5             -0.69803506  0.21491928    5.144598
```

The following is an example of a file that can be read or written from the Motion Settings Dialog Box (p. 2749) when **Regular** is selected from the **Control Point Distribution** list in the **Regions** tab of the Mesh Morpher/Optimizer Dialog Box (p. 2734):

```
Reg     CP      Par      X       Y       Z
def-0   2       par1     -1      0       0
def-0   4       par1     2       -1      3
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
def-0   2       par2     0       1       0
def-1   2       par3     0       0       1
def-1   3       par1     2       0       2
```

The following is an example of a file that can be read or written from the Motion Settings Dialog Box (p. 2749) when **Unstructured** is selected from the **Control Point Distribution** list in the **Regions** tab of the Mesh Morpher/Optimizer Dialog Box (p. 2734):

```
Motion Definition
Name         Type        Par         Dir-x       Dir-y       Dir-z       Orig-x      Orig-y      Orig-z
rad-par1-1   Rad         par-1       0           0           1           0           0           0
tra-par2-1   Trans       par-2       1           1           1
rot-par3-1   Rot         par-3       1           0           0           2           1           1

Assignment to Control Points
Name         Control Points...
rad-par1-1   1           2           3           4           5           6           7
```

When creating or editing a text file used to set up the mesh morpher/optimizer, note the following:

- The file can be created from nothing using a text editor or spreadsheet program, as long as it adheres to the formats described in this section. An easier alternative is to apply some sample definitions using the appropriate dialog box, write a file, and then edit the file using a text editor or spreadsheet program.
- The file must be a tab-delimited ASCII text file.
- The names of the deformation regions (for example, `def-0`), deformation parameters (for example, `par1`), and motions (for example, `tra-par2-1`) must correspond to those that exist in the intended case file.
- When defining control points, the coordinates must lie within a deformation region in the intended case file.
- For the motion settings, the control point numbers must range between 1 and the maximum number of available control points in the intended case file.
- The direction components and coordinates can be any real numbers.

B.3. Shell Conduction Settings File Format

This section describes the format of the CSV files that can define shell conduction settings, as described in Managing Shell Conduction Walls (p. 840). The following is an example of such a file:

```
Zone ID,Zone Name,Layer Number,Material,Layer Thickness (m),Heat Generation Rate (w/m3)
15,wall-1,1,substrate,5.00E-08,0
15,wall-1,2,substrate,5.00E-08,0
15,wall-1,3,substrate,5.00E-08,0
15,wall-1,4,substrate,5.00E-08,0
15,wall-1,5,gold,2.50E-08,0
15,wall-1,6,gold,2.50E-08,0
16,wall-2,1,silicon,5.00E-08,6.25E+11
16,wall-2,2,silicon,5.00E-08,6.25E+11
16,wall-2,3,substrate,5.00E-08,0
```

When creating or editing a file that defines the shell conduction settings, note the following:

- The file can be created from nothing using a text editor or spreadsheet program, as long as it adheres to the format described in this section. An easier alternative is to apply some sample shell conduction definitions using the Shell Conduction Manager Dialog Box (p. 2806), generate a file using the **Write...** button, and then edit the file using a text editor or spreadsheet program.
- The file must be a comma-delimited ASCII file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The first line contains the column headings shown in the previous example, and then each of the subsequent lines define the settings for a layer.
- The zone IDs, zone names, layer numbers, and materials (for example, `wall-1`, `substrate`) must correspond to those that exist in the intended case file.
- The layer thicknesses must be positive, nonzero values.
- Information will not be written for any wall that defines the heat generation rate using a UDF.

B.4. 3D Fan Curve File Format

This section describes the format of the ASCII text files that can define the relationship between pressure and flow rate for all of the 3D fan cell zones in a case file, as described in 3D Fan Zones (p. 287). The following is an example of such a file:

```
cell zone id
17 !CELL_ID
Pressure(Pa) Flowrate(m3/s)
-324.0 1.255
-215.0 1.162
-109.0 1.032
0.0 0.997
63.0 0.913
105.0 0.862
302.0 0.584
394.0 0.492
406.0 0.432
443.0 0.365
cell zone id
18 !CELL_ID
Pressure(Pa) Flowrate(m3/s)
-333.0 1.130
-215.0 1.122
-165.0 1.064
0.0 0.981
42.0 0.912
90.0 0.855
112.0 0.786
303.0 0.546
344.0 0.492
395.0 0.451
411.0 0.399
442.0 0.324
```

When creating or editing a file that defines the 3D fan zone curve, note the following:

- The file can be created from nothing using a text editor or spreadsheet program, as long as it adheres to the format described in this section.
- The file must be a tab-delimited ASCII file.
- A single file can define multiple cell zones, but it must be read in each of the applicable **Fluid** dialog boxes.
- For each section that defines the curve for a cell zone, the first three lines must follow the convention shown in the previous example, and then each of the subsequent lines must list the experimental results.
- The zone IDs (for example, 12) must correspond to those that exist in the intended case file.
- The units must match those in the case file.

Appendix C. Nomenclature

A	Area (m^2, ft^2)
$\vec{a}$	Acceleration (m/s^2, ft/s^2)
a	Local speed of sound (m/s, ft/s)
c	Concentration (mass/volume, moles/volume)
C_D	Drag coefficient, defined different ways (dimensionless)
c_p, c_v	Heat capacity at constant pressure, volume (J/kg-K, Btu/lb_m- °F)
d	Diameter; $d_p D_p$, particle diameter (m, ft)
D_H	Hydraulic diameter (m, ft)
$_{ij}D$	Mass diffusion coefficient (m^2/s, ft^2/s)
E	Total energy, activation energy (J, kJ, cal, Btu)
f	Mixture fraction (dimensionless)
$\vec{F}$	Force vector (N, lb_f)
F_D	Drag force (N, lb_f)
$\vec{g}$	Gravitational acceleration (m/s^2, ft/s^2); standard values = 9.80665 m/s^2, 32.1740 ft/s^2
Gr	Grashof number ≡ ratio of buoyancy forces to viscous forces (dimensionless)
H	Total enthalpy (energy/mass, energy/mole)
h	Heat transfer coefficient (W/m^2-K, Btu/ft^2-h- °F)
h	Species enthalpy; h^0, standard state enthalpy of formation (energy/mass, energy/mole)
I	Radiation intensity (energy per area of emitting surface per unit solid angle)
J	Mass flux; diffusion flux (kg/m^2-s, lb_m/ft^2-s)
K	Equilibrium constant = forward rate constant/backward rate constant (units vary)
k	Kinetic energy per unit mass (J/kg, Btu/lb_m)
k	Reaction rate constant, for example, k_1, k_{-1}, $k_{f,r}$, $k_{b,r}$ (units vary)
k	Thermal conductivity (W/m-K, Btu/ft-h- °F)
k_B	Boltzmann constant (1.38×10^{-23} J/molecule-K)
k, k_c	Mass transfer coefficient (units vary); also K, K_c
ℓ, l, L	Length scale (m, cm, ft, in)
Le	Lewis number ≡ ratio of thermal diffusivity to mass diffusivity (dimensionless)
m	Mass (g, kg, lb_m)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$\dot{m}$ Mass flow rate (kg/s, lb_ms)

M_w Molecular weight (kg/kmol, lb_m/lb_mmol)

M Mach number ≡ ratio of fluid velocity magnitude to local speed of sound (dimensionless)

Nu Nusselt number ≡ dimensionless heat transfer or mass transfer coefficient (dimensionless); usually a function of other dimensionless groups

p Pressure (Pa, atm, mm Hg, lb_f/ft^2)

Pe Peclet number $\equiv Re \times Pr$ for heat transfer, and $\equiv Re \times Sc$ for mass transfer (dimensionless)

Pr Prandtl number ≡ ratio of momentum diffusivity to thermal diffusivity (dimensionless)

Q Flow rate of enthalpy (W, Btu/h)

q Heat flux (W/m^2, Btu/ft^2-h)

R Gas-law constant (8.31447 $\times 10^3$ J/kmol-K, 1.98588 Btu/lb_mmol- °F)

r Radius (m, ft)

$\mathcal{R}$ Reaction rate (units vary)

Ra Rayleigh number $\equiv Gr \times Pr$; measure of the strength of buoyancy-induced flow in natural (free) convection (dimensionless)

Re Reynolds number ≡ ratio of inertial forces to viscous forces (dimensionless)

S Total entropy (J/K, J/kmol-K, Btu/lb_mmol- °F)

s Species entropy; s^0, standard state entropy (J/kmol-K, Btu/lb_mmol- °F)

Sc Schmidt number ≡ ratio of momentum diffusivity to mass diffusivity (dimensionless)

S_{ij} Mean rate-of-strain tensor (s^{-1})

T Temperature (K, °C, °R, °F)

t Time (s)

U Free-stream velocity (m/s, ft/s)

u, v, w Velocity magnitude (m/s, ft/s); also written with directional subscripts (for example, v_x, v_y, v_z, v_r)

V Volume (m^3, ft^3)

$\vec{v}$ Overall velocity vector (m/s, ft/s)

We Weber number ≡ ratio of aerodynamic forces to surface tension forces (dimensionless)

X Mole fraction (dimensionless)

Y Mass fraction (dimensionless)

α Permeability, or flux per unit pressure difference (L/m^2-h-atm, ft_3/ft^2-h-(lb_f/ft^2))

α Thermal diffusivity (m^2/s, ft^2/s)

α Volume fraction (dimensionless)

β Coefficient of thermal expansion (K_{-1})

γ Porosity (dimensionless)

γ Ratio of specific heats, c_p/c_v (dimensionless)

Δ Change in variable, final − initial (for example, Δp, Δt, ΔH, ΔS, ΔT)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

δ	Delta function (units vary)
ε	Emissivity (dimensionless)
ε	Lennard-Jones energy parameter (J/molecule)
ε	Turbulent dissipation rate (m^2/s^3, ft^2/s^3)
ε	Void fraction (dimensionless)
η	Effectiveness factor (dimensionless)
η', η''	Rate exponents for reactants, products (dimensionless)
θ_r	Radiation temperature (K)
λ	Molecular mean free path (m, nm, ft)
λ	Wavelength (m, nm, Å, ft)
μ	Dynamic viscosity (cP, Pa-s, lb_m/ft-s)
ν	Kinematic viscosity (m^2/s, ft^2/s)
ν', ν''	Stoichiometric coefficients for reactants, products (dimensionless)
ρ	Density (kg/m^3, lb_m/ft^3)
σ	Stefan-Boltzmann constant ($5.67x10^{-8}$ W/m^2-K^4)
σ	Surface tension (kg/m, dyn/cm, lb_f/ft)
σ_s	Scattering coefficient (m^{-1})
$\bar{\bar{\tau}}$	Stress tensor (Pa, lb_f/ft^2)
τ	Shear stress (Pa, lb_f/ft^2)
τ	Time scale, for example, τ_c, τ_p, τ_c (s)
τ	Tortuosity, characteristic of pore structure (dimensionless)
ϕ	Equivalence ratio (dimensionless)
ϕ	Thiele modulus (dimensionless)
Ω	Angular velocity; Ω_{ij}, Mean rate of rotation tensor (s^{-1})
ω	Specific dissipation rate (s^{-1})
Ω,Ω'	Solid angle (degrees, radians, gradians)
Ω_D	Diffusion collision integral (dimensionless)

Appendix D. Controlling CHEMKIN-CFD Solver Parameters Using Text Commands

You have access to many parameter settings that can be used to control or improve the performance and convergence behavior of the CHEMKIN-CFD solver within ANSYS Fluent. These parameters are accessed through the ANSYS Fluent Text User Interface (TUI), through typed text commands. This appendix describes the available parameters, their default values, and their recommended use.

In general, default settings for the CHEMKIN-CFD parameters should be sufficient for most problems. However, it may be necessary to change these settings to improve performance for specific types of problems. In particular, the most appropriate solver parameters may vary depending on the nature of the chemistry set.

For example, for chemistries with many trace species that have a large impact on solution results (that is, the chemistry is "stiff"), solution tolerances should be relatively small (for example, 1.E-9 to 1.E-12 for absolute tolerances and 1.E-4 to 1.E-5 for relative tolerances). For chemistry descriptions where all of the species included are within a few orders of magnitude in terms of mass fraction, however, much looser tolerances are more appropriate. Also, depending on the characteristic time scales of the dominant chemical reactions, you may need to adjust the maximum time-step used by the CHEMKIN-CFD solver.

```

Table 1: Summary of Basic CHEMKIN-CFD Parameters (p. 2876) and Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877) summarize basic and advanced parameters, respectively. These tables include

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

descriptions of the default values and physical units, where applicable, for each of the CHEMKIN-CFD parameters, as well as a discussion of the recommended parameter usage.

Table 1: Summary of Basic CHEMKIN-CFD Parameters

Parameter	Usage	Default Value
`Print Level`	Controls the level of diagnostic printing to the CHEMKIN-CFD diagnostic output file, where 0 indicates no printing, 1 indicates standard printing, and 2 enables a verbose level of printing that provides details about the solver operations. Note that diagnostic output can significantly contribute to compute time such that high levels of printing should be avoided unless problems are encountered that require diagnosis.	0
`Absolute Tolerance for Gas-phase Species`	Controls the smallest value of a species mass fraction that will be tracked by the CHEMKIN-CFD solver convergence algorithm. This should represent either the smallest mass fraction that is of importance in the problem or, for stiff chemistry, the smallest fraction pertaining to a species that can have a significant effect through chemical reaction on other species of interest. Typical values range from 1.E-6 to 1.E-12.	1.E-8
`Relative Tolerance for Gas-phase Species`	Controls the accuracy to which gas species mass fractions are resolved. Roughly this parameter controls the number of significant digits in the solution. However, this parameter can also be important for convergence of problems with stiff chemistry, as it is important to sufficiently resolve species that have a major impact on trace species of interest. Typical values range from 1.E-3 to 1.E-5.	1.E-4
`Absolute Tolerance for Surface Species`	Controls the smallest value of a surface species site fraction that will be tracked by the CHEMKIN-CFD solver convergence algorithm. This should represent either the smallest mass fraction that is of importance in the problem or, for stiff chemistry, the smallest fraction pertaining to a species that can have a significant effect through chemical reaction on other species of interest. Typical values range from 1.E-6 to 1.E-15.	1.E-8

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameter	Usage	Default Value
Relative Tolerance for Surface Species	Controls the accuracy to which surface species site fractions are resolved. Roughly this parameter controls the number of significant digits in the solution. However, this parameter can also be important for convergence of problems with stiff chemistry, as it is important to sufficiently resolve species that have a major impact on trace species of interest. Typical values range from 1.E-3 to 1.E-5.	1.E-4

Table 2: Summary of Advanced CHEMKIN-CFD Parameters

Parameter	Usage	Default Value
Pseudo Time-stepping Solver Option	Determines which solver to use during pseudo time-stepping used to improve the initial guess in a cell for steady-state simulations. By default, it is set to 1 and a robust solver with strict error control will be used when the steady-state algorithm requires time-stepping assistance. You may optionally revert to a less accurate time-stepping technique, which may be computationally faster but more prone to failure, by setting it to zero. See Advanced Parameters Used in the Steady-State Solution Algorithm (p. 2879) for more information. This parameter is ignored for transient simulations.	1
Pseudo Time-stepping Size	This option is only relevant if the Pseudo Time-stepping Solver Option is set to 1 (the default setting). This controls the time interval for time-stepping when time-stepping is used to assist a steady-state calculation. See Advanced Parameters Used in the Steady-State Solution Algorithm (p. 2879) for more information. A value of 1.E-4 seconds is recommended for combustion problems.	1.E-6 [seconds]
Maximum Pseudo Time-stepping Attempts	This parameter controls how many iterations between time-stepping and steady-state solution attempts can be tried before the solver gives up and registers a failure for the cell. Usually only one attempt is needed, but the maximum can be increased from this default value in difficult cases. Note that in some cases it is most efficient to ignore a small number of cell failures early on in the simulation as long as these cells recover on subsequent iterations. See Advanced Parameters Used in the Steady-State Solution Algorithm (p. 2879) for more information. A value of 10 to 100 is recommended to minimize error messages.	1
Maximum Time Step Allowed	Maximum pseudo time-step value for time integration during steady-state solution. This value is relevant to steady-state simulations only.	1.E-2 [seconds]

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameter	Usage	Default Value
`Minimum Time Step Allowed`	Minimum pseudo time-step value for time integration during steady-state solution. This value is relevant to steady-state simulations only.	1.E-10 [seconds]
`Initial Time Step for Solver`	Initial time-step value for use in time integration. By default, the solver will automatically choose an appropriate initial time step, which is the recommended approach. In rare cases, however, control of initial time step value may improve convergence behavior.	0 (i.e., not specified) [seconds]
`Upper Bound for Gas-species Mass Fraction`	Sets the upper bounds for the gas-phase species mass fractions during steady-state solution. In some cases, it may help convergence to allow species to go slightly over the physical bounds during interim steady-state iterations rather than forcing the bounds to be one.	1.01
`Lower Bound for Gas-species Mass Fraction`	Sets the lower bounds for the gas-phase species mass fractions during steady-state solution. In some cases, it may help convergence to allow species to go slightly negative during interim steady-state iterations rather than forcing the bounds to be zero. A value as negative as about -1.E-4 may be used.	-1.E-12
`Upper Bound for Surface Site Fraction`	Sets the upper bounds for the surface species site fractions during steady-state solution. In some cases, it may help convergence to allow species to go slightly over the physical bounds during interim steady-state iterations rather than forcing the bounds to be one.	1.1
`Lower Bound for Surface Site Fraction`	Sets the lower bounds for the surface species site fractions during steady-state solution. In some cases, it may help convergence to allow species to go slightly negative during interim steady-state iterations rather than forcing the bounds to be zero.	-1.E-4
`Small Positive Value to Replace Negative Species Fractions`	This value will be used to substitute any non-positive species fractions during interim steady-state iterations. In some cases, setting this to a very small positive number may aid convergence for the steady-state solver.	1.E-12
`Enter Auxiliary Input Filename`	Currently not used. Provided for future use.	""
`Enter Arbitrary String`	Currently not used. Provided for future use.	""
`Enter Arbitrary Value`	Currently not used. Provided for future use.	0

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

D.1. Advanced Parameters Used in the Steady-State Solution Algorithm

Many of the parameters listed in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877) are relevant only for steady-state solution. Here a brief description of the steady-state solution algorithm is provided in order to clarify the role of these parameters and their impact on solution convergence.

For steady-state problems, the ANSYS CHEMKIN-CFD solver is called by ANSYS Fluent for each cell during each Fluent iteration towards a steady state. Within each cell, the chemistry solver will attempt to determine an appropriate steady-state using a combination of a modified Newton-iteration procedure and a "pseudo" time-stepping procedure. The Newton-iteration method is used to attempt to directly iterate towards the desired solution. However, at early times in the simulation, this procedure may not succeed, especially when the initial guess is far from the actual steady solution. In such cases, the CHEMKIN-CFD module will automatically switch to a time-stepping mode to advance the initial guess closer to the physical solution. After taking a certain number of time steps, the Newton-iteration algorithm tries again. In this way, the steady-state solution is achieved with a minimum amount of time-stepping. Since time-stepping is computationally expensive, this results in a computationally efficient but robust method for achieving the steady-state solution.

You can control the number of times the CHEMKIN-CFD module is allowed to use time-stepping to advance a solution towards steady-state before reporting a failure for any individual cell (see `Maximum Pseudo Time-stepping Attempts` in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877)).

In performing the pseudo time-stepping procedure, there are two solver options - a "basic" time-stepping procedure and a "robust" time-stepping procedure (see `Pseudo Time-stepping Solver Option` in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877)). The "robust" procedure (default) uses an integration method that is very accurate with error control enforced on all solution variables. This can sometimes be more time consuming but is generally more reliable in tracking transient states towards an eventual steady condition. The "basic" solver option is much more approximate in the time-tracking technique, but is often faster and sufficiently robust for some cases.

When the "robust" time-stepping procedure is selected, you can specify the time interval used for each attempt to advance the solution using time integration (See `Pseudo Time-stepping Size` in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877)). The actual time steps used during the time integration will be automatically determined based on the rate of change of the solution variables. The time interval, however, controls the total time advanced before returning the solution to be used as the next initial guess in the Newton-iteration.method.

In addition to the pseudo time-stepping controls, you may also control certain parameters that affect the convergence behavior of the Newton-iteration algorithm itself. In particular, you can modify the solution bounds imposed during the iterations (see `Upper Bounds and Lower Bounds parameters` in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877)). By extending the bounds slightly outside of the physical limits, the Newton iteration can more easily resolve species fractions that are very near to those limits. This can be especially helpful in early iterations where variable values may be changing rapidly. It is also helpful to try to "reset" any negative species fractions to very small values between iterations, so that these values do not have unphysical effects on reaction rates. For this purpose, you can specify a small positive value, which should not exceed the specified absolute tolerance, as a replacement value for negative fractions (see `Small Positive Value to Replace Negative Species Fractions` in Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

D.2. Setting Up Monitor Cells for the ANSYS CHEMKIN-CFD Chemistry Solver

At the same level of the basic-options and advanced-options in the Text User Interface, that is, under `define/models/species/CHEMKIN-CFD-parameters`, you can add, delete, and list `monitor cells`.

By specifying a `monitor cells` in the CHEMKIN-CFD options, you are requesting additional printout diagnostics for every iteration or time-step at this cell location. Such printout can add significantly to computational times and should be avoided unless there is a problem has been encountered and more diagnosis is needed.

Important

Using monitor cells may add significantly to the job run time. It is recommended that monitor cells only be included if extra diagnosis is required to resolve a convergence problem or local mesh issue, for example.

Monitor cells are added using the `add-cell-monitor` option and providing the physical coordinates that correspond as closely as possible to the centroid location of the desired cell in the Fluent mesh. You can create more than one cell monitor and you can be delete all of them using the `delete-cell-monitor option`. You may also list the currently activated monitor cells using the `list-cell-monitor option`.

D.3. Diagnostic Files and Error Messages

In addition to the standard ANSYS Fluent files produced during a run using the CHEMKIN-CFD solver, the CHEMKIN-CFD module creates special files to hold diagnostic output and error messages that may be helpful in diagnosing a problem with the pre-processing or run steps. In addition, error messages may be written in the ANSYS Fluent Graphical User Interface window during run-time processing.

Table 3: Diagnostic Output Files Created During a CHEMKIN-CFD Run (p. 2880) lists additional files that may be created by the chemistry solver, the data printed to them, and an indication of where they are created in the ANSYS Fluent run process. All files are created within the working directory of the simulation run. The actual names of many of the files will depend on variables, such as the chemistry-set file names, the case-file name, the cell number, iteration or time-step number, and the processor id. Such variables are indicated by < > in Table 3: Diagnostic Output Files Created During a CHEMKIN-CFD Run (p. 2880).

Table 3: Diagnostic Output Files Created During a CHEMKIN-CFD Run

Filename	When File Is Created	Contents Description
`<gas_chemistry>.out`	Always created during pre-processing, upon saving the CHEMKIN mechanism definition.	This file echoes back the gas-phase chemistry reaction set, species names, and elements in formatted text. In addition, detailed error messages are contained in this file in case an error is encountered while processing the gas-phase chemistry input file and gas-phase thermodynamic data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Filename	When File Is Created	Contents Description
chem.asc	Always created during pre-processing, upon saving the CHEMKIN mechanism definition.	A "Linking File" used to transfer the pre-processed information to the CHEMKIN-CFD module at run-time. This file is typically not viewed by the user, but may occasionally be requested by Technical Support during problem diagnosis.
<surface_chemistry>.out	Created during pre-processing, only if surface chemistry box is checked in CHEMKIN mechanism definition.	This file echoes back the surface chemistry reaction set and the surface phase and species names. In addition, detailed error messages are contained in this file in case an error is encountered while processing the surface chemistry input file and surface-species thermodynamic data.
surf.asc	Created during pre-processing, only if surface chemistry box is checked in CHEMKIN mechanism definition.	A "Linking File" used to transfer the pre-processed information to the CHEMKIN-CFD module at run-time. This file is typically not viewed by the user, but may occasionally be requested by Technical Support during problem diagnosis.
<transport_data>.out	Created during pre-processing, only if transport-property box is checked in CHEMKIN mechanism definition.	This file echoes back the transport-data fitting coefficients in formatted text. In addition, detailed error messages are contained in this file in case an error is encountered while processing the gas-phase transport data.
tran.asc	Created during pre-processing, only if transport-property box is checked in CHEMKIN mechanism definition.	A "Linking File" used to transfer the pre-processed information to the CHEMKIN-CFD module at run-time. This file is typically not viewed by the user, but may occasionally be requested by ANSYS Technical Support during problem diagnosis.
KINetics-log.txt	Created when the simulation run is initiated in the subdirectory fluentKINlog.	Messages are written to this file that record the progress of chemistry-set pre-processor and CHEMKIN-CFD solver. The printing level during the simulation run can be controlled by Print Level as indicated in Table 1: Summary of Basic CHEMKIN-CFD Parameters (p. 2876).
KIN-CELL_<cell_id>_<iteration_number>.DBG	Created for Monitor Cells (see Setting Up Monitor Cells for the ANSYS CHEMKIN-CFD Chemistry Solver (p. 2880)) at every iteration or time-step, any time that the Print Level (Table 1: Summary of	Includes debug information, including the actual input sent into the CHEMKIN-CFD module by ANSYS Fluent for the particular cell and iteration. This information may be requested by ANSYS Technical Support when diagnosing cell failures.

Filename	When File Is Created	Contents Description
	Basic CHEMKIN-CFD Parameters (p. 2876)) is >0. Also created any time that a cell fails in the CHEMKIN-CFD solver and the `Print Level` is >0.	

D.4. Error Messages Printed in the ANSYS Fluent Graphical User Interface

Advanced Parameters Used in the Steady-State Solution Algorithm (p. 2879) lists possible error messages that may appear in the ANSYS Fluent Graphical User Interface during run using the CHEMKIN-CFD solver. The table includes recommended actions that may help resolve or narrow down the problem. In some cases, you may be referred to some of the additional diagnostic output files generated by the CHEMKIN-CFD module and listed in Table 3: Diagnostic Output Files Created During a CHEMKIN-CFD Run (p. 2880).

Table 4: Error Messages that May Be Printed to the Fluent GUI

Setting	Value
`Cannot read gas-phase chemistry input file.`	Verify the filename and file path for the gas-phase chemistry input file in the **CHEMKIN Mechanism Import** dialog box and re-import.
`Cannot read surface chemistry input file.`	Verify the filename and file path for the surface chemistry input file in the **CHEMKIN Mechanism Import** dialog box and re-import.
`Cannot read thermodynamic data file.`	Verify the filename and file path for the thermodynamic data file in the **CHEMKIN Mechanism Import** dialog box and re-import.
`Cannot read transport properties data file.`	Verify the filename and file path for the transport-property data file in the **CHEMKIN Mechanism Import** dialog box and re-import.
`Cannot read gas-phase chemistry linking data file during gas-phase pre-processing.`	Check the `<gas_chemistry>.out` file in the working directory for error messages.
`Cannot read gas-phase chemistry linking data file during surface pre-processing.`	Check the `<gas_chemistry>.out` file in the working directory for error messages.
`Cannot read gas-phase chemistry linking data file during transport pre-processing.`	Check the `<gas_chemistry>.out` file in the working directory for error messages.
`Cannot read surface chemistry linking data file during surface pre-processing.`	Check the `<surface_chemistry>.out` file in the working directory for error messages.
`Cannot read transport properties linking data file during transport pre-processing.`	Check the `<transport_data>.out` file in the working directory for error messages.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting	Value
Cannot write gas-phase chemistry output file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Cannot write surface chemistry output file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Cannot write transport properties output file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Cannot write gas-phase chemistry linking data file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Cannot write surface chemistry linking data file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Cannot write transport properties linking data file.	Check file permissions on working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
Gas-phase chemistry file is NULL.	Verify gas-phase chemistry file path in the CHEMKIN Mechanism definition and re-import the chemistry files.
Surface chemistry file is NULL.	Verify surface-chemistry file path in the CHEMKIN Mechanism definition and re-import the chemistry files.
Thermodynamic data file is NULL.	Verify thermodynamic-data file path in the CHEMKIN Mechanism definition and re-import the chemistry files
Transport properties data file is NULL.	Verify transport-data file path in the CHEMKIN Mechanism definition and re-import the chemistry files.
Failure in pre-processing of gas-phase chemistry mechanism.	Check the <gas_chemistry>.out file in the working directory for error messages.
Failure in pre-processing of surface chemistry mechanism.	Check the <surface_chemistry>.out file in the working directory for error messages.
Failure in pre-processing of transport properties.	Check the <transport_data>.out file in the working directory for error messages.
Failure in CHEMKIN Gas-phase library call.	Check to see if the ANSYS Fluent solution has diverged or has unphysical values for the variables. Try turning Print Level > 0 and

Setting	Value
	setting a monitor cell to obtain more information.
`Failure in CHEMKIN Surface library call.`	Check to see if the ANSYS Fluent solution has diverged or has unphysical values for the variables. Try turning `Print Level` > 0 and setting a monitor cell to obtain more information.
`Failure in CHEMKIN Transport library call.`	Check to see if the ANSYS Fluent solution has diverged or has unphysical values for the variables. Try turning `Print Level` > 0 and setting a monitor cell to obtain more information.
`Need to run CHEMKIN-CFD PrePro-cess first.`	Re-import the CHEMKIN chemistry set and make sure it is selected in the **Species Model** dialog box (under **Setup**/**Models**).
`No surface data for the chemistry set.`	Either de-select the Surface Chemistry option in the **CHEMKIN Mechanism Import** dialog box, or make sure that a valid surface chemistry file is indicated.
`No transport data for the chem-istry set.`	Either de-select the Transport Data option in the **CHEMKIN Mechanism Import** dialog box, or make sure that a valid transport data file is indicated.
`Failure in writing data into the diagnostics file.`	Check file permissions on the working directory and make sure that there is only one CHEMKIN-CFD process using these files at a time.
`Error in CHEMKIN-CFD model, see diagnostic output file for de-tails.`	Check the `KINetics-log.txt` file in the subdirectory `fluentKINlog` for error messages. See Error Messages Printed in the ANSYS Fluent Graphical User Interface (p. 2882) for more information.

D.5. Diagnostic Messages in the `KINetics-log.txt` File

The `KINetics-log.txt` file is a "catch-all" for many diagnostic messages that are generated by the CHEMKIN-CFD module. The most common types of messages are error messages related to setup or cell convergence.

Cell-convergence error messages can take a variety of forms. The most common are summarized in Table 5: Other Error Messages in `KINetics-log.txt` (p. 2885). In general, if there are just a few failed cells at the beginning of a simulation it is safe to ignore them. When the number of failed cells continues to grow with each iteration, there is likely an issue with the problem set-up or with the chemistry data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Table 5: Other Error Messages in KINetics-log.txt (p. 2885) contains some broad suggestions of ways to improve cell-convergence behavior based on the type of cell failure message received.

Table 5: Other Error Messages in KINetics-log.txt

Error Message	Recommended Action
FAILURE INITIALIZING SETTINGS FOR THE KINetics STEADY-STATE GAS-PHASE CHEMISTRY SOLVER	Most likely suggests an error in setting the convergence criteria (that is absolute and relative tolerance) and the pseudo-steady-state time stepping parameters. Check that the user-provided values are reasonable.
WARNING: Exceeded allowed time-stepping intervals in cell	Indicates that a convergence problem was encountered during steady-state solution, where time-stepping is used to help advance the steady-state iterations. In this case, you can either ignore the message (see if the cell convergence recovers in subsequent iterations) or try to increase either the time interval or the number of allowed time-stepping intervals (See Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877) for more information).
KINETICS ERROR: SOLUTION FAILED	Indicates that the cell failed to converge (either steady-state or transient).In this case, you can either ignore the message (see if the cell convergence recovers in subsequent iterations) or try to modify some of the user-controlled parameters to improve convergence (See Table 2: Summary of Advanced CHEMKIN-CFD Parameters (p. 2877) for more information).
Warning - The transient chemistry solver tried 500 steps without convergence in this cell; 500 more steps will be allowed	Indicates that the problem is difficult to converge so that the transient solver is taking extra steps. However, it is only a warning and the cell has not actually failed. If you receive an excessive number of these messages, try reducing the absolute or relative solution tolerances that control the CHEMKIN-CFD solver.
KINETICS ERROR: Problem getting species names; Check that the CHEMKIN files have been processed correctly	Indicates a possible error in the pre-processing of the gas-phase chemistry input file. Check the <gas_chemistry>.out file for error messages.
KINETICS ERROR: Problem getting surface chemistry info; Check that the CHEMKIN files have been processed correctly	Indicates a possible error in the pre-processing of the surface chemistry input file. Check the <surface_chemistry>.out file for error messages.
DASPK:...	These messages are from the CHEMKIN-CFD transient solver, DASPK. The exact message

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Error Message	Recommended Action
	usually contains more information about the problem.

Note

During steady-state simulations, once an iteration occurs where there are no failed cells, the effect of previously failed cells in earlier iterations is completely erased.
